As outlined above, the detector may further comprise at least one transfer device. The transfer device preferably may be positioned in a light path in between the object and the detector. As used herein, a transfer device generally is an arbitrary optical element adapted to guide the light beam onto the optical sensor. The guiding may take place with unmodified properties of the light beam or may take place with imaging or modifying properties. Thus, generally, the transfer device might have imaging properties and/or beam-shaping properties, i.e. might change a beam waist and/or a widening angle of the light beam and/or a shape of the cross-section of the light beam when the light beam passes the transfer device. The transfer device, as an example, may comprise one or more elements selected from the group consisting of a lens and a mirror. The mirror may be selected from the group consisting of a planar mirror, a convex mirror and a concave mirror. Additionally or alternatively, one or more prisms may be comprised. Additionally or alternatively, one or more wavelength-selective elements may be comprised, such as one or more filters, specifically color filters, and/or one or more dichroitic mirrors. Again, additionally or alternatively, the transfer device may comprise one or more diaphragms, such as one or more pinhole diaphragms and/or iris diaphragms.

The transfer device can for example comprise one or a plurality of mirrors and/or beam splitters and/or beam deflecting elements in order to influence a direction of the electromagnetic radiation. Alternatively or additionally, the transfer device can comprise one or a plurality of imaging elements which can have the effect of a converging lens and/or a diverging lens. By way of example, the optional transfer device can have one or a plurality of lenses and/or one or a plurality of convex and/or concave mirrors. Once again alternatively or additionally, the transfer device can have at least one wavelength-selective element, for example at least one optical filter. Once again alternatively or additionally, the transfer device can be designed to impress a predefined beam profile on the electromagnetic radiation, for example, at the location of the sensor region and in particular the sensor area. The above-mentioned optional embodiments of the optional transfer device can, in principle, be realized individually or in any desired combination. The at least one transfer device, as an example, may be positioned in front of the detector, i.e. on a side of the detector facing towards the object.

In addition to the at least one longitudinal coordinate of the object, at least one transversal coordinate of the object may be determined. Thus, generally, the evaluation device may further be adapted to determine at least one transversal coordinate of the object by determining a position of the light beam on the matrix of pixels. As an example, the evaluation device may be adapted to determine a center of illumination of the at least one matrix by the light beam, wherein the at least one transversal coordinate of the object is determined by evaluating at least one coordinate of the center of illumination. Thus, the coordinate of the center of illumination may be a pixel coordinate of the center of illumination. As an example, the matrix may comprise rows and columns of pixels, wherein the row number of the light beam and/or the center of the light beam within the matrix may provide an x-coordinate, and wherein the column number of the light beam and/or the center of the light beam within the matrix may provide a y-coordinate.

By providing one or more transversal coordinates, such as x- and/or y-coordinates, the evaluation device is adapted to provide at least one three-dimensional position of the object.

Further options of the present invention refer to potential embodiments of the at least one optical sensor. Generally, an arbitrary optical sensor device having a matrix of pixels used, such as an optical sensor device selected from the group consisting of: an inorganic semiconductor sensor device such as a CCD chip and/or a CMOS chip; an organic semiconductor sensor device. In the latter case, as an example, the optical sensor may, for example, comprise at least one organic photovoltaic device having a matrix of pixels. As used herein, an organic photovoltaic device generally refers to a device having at least one organic photosensitive element and/or at least one organic layer. Therein, generally, any type of organic photovoltaic device may be used, such as organic solar cells and/or an arbitrary device having at least one organic photosensitive layer. As an example, an organic solar cell and/or a dye-sensitized organic solar cell may be comprised. Further, a hybrid device may be used, such as inorganic – organic photovoltaic devices. The detector may comprise one or more organic photovoltaic devices and/or may comprise one or more inorganic photovoltaic devices and/or may comprise a combination consisting of one or more organic photovoltaic devices and one or more inorganic photovoltaic devices.

The optical sensor specifically may comprise at least one dye-sensitized solar cell having at least one patterned electrode. For potential embodiments of dye-sensitized solar cells, reference may be made to WO 2012/110924 A1 and to US provisional applications number 61/739,173 and 61/749,964. The device setups of the dye-sensitized solar cells disclosed therein, specifically of the optical sensors disclosed therein, may generally also be applied to the present invention, with the proviso that at least one of the electrodes of these dye-sensitized solar cells is patterned in order to provide a plurality of pixels. Thus, as an example, one or both of the first and second electrodes of the dye-sensitized solar cells disclosed in the named documents may be patterned. As an example, the first electrode may be patterned to provide a plurality of parallel horizontal stripes, and the second electrode may be patterned to provide a plurality of parallel vertical stripes, or vice versa. Thus, at each crossing point of a stripe of the first electrode and a stripe of the second electrode, a pixel is provided which, by electrically

contacting the respective stripes of the electrodes and measuring an electrical current and/or voltage, may be read out.

The optical sensor specifically may comprise at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid p-semiconducting organic material, and at least one second electrode, with the at least one n-semiconducting metal oxide, the at least one dye and the at least one p-semiconducting organic material being embedded in between the first electrode and the second electrode.

As mentioned above and as will be outlined in further detail below, generally, for potential embodiments of materials or layer combinations which may be used for the first electrode, the at least one n-semiconducting metal oxide, the at least one dye, the at least one p-semiconducting organic material and the at least one second electrode, reference may be made to the above-mentioned WO 2012/110924 A1 as well as to US provisional applications 61/739,173, filed on December 19, 2012, and 61/749,964, filed on January 8, 2013. Still, other embodiments are feasible. Thus, as an example, the n-semiconducting metal oxide may comprise a nanoporous layer of a metal oxide and a dense layer of a metal oxide. The metal oxide preferably may be or may comprise titanium dioxide. For potential dyes, reference may be made to the dyes mentioned in the above-mentioned documents, such as to the dye ID 504. Further, with regard to potential p-semiconducting organic materials, as an example, spiro-MeOTAD may be used, as disclosed in one or more of the above-mentioned documents. Similarly, for potential electrode materials, both transparent and intransparent, reference may be made to these documents. As outlined above, other embodiments are feasible.

Both the first electrode and the second electrode may be transparent. However, other electrode setups may be possible.

As outlined above, preferably, at least one of the first electrode and the second electrode may be a patterned electrode. Thus, as an example, one or both of the first electrode and the second electrode may comprise a plurality of electrode stripes, such as horizontal electrode stripes and/or vertical electrode stripes. As an example for pixelated optical sensors which may also be used in the context of the present invention, reference may be made to EP patent application No. 13171898.3, the full content of which is herewith included by reference. Still, other pixelated optical sensors may be used.

As an example, as outlined above, the first electrode may comprise a plurality of electrode stripes and the second electrode may comprise a plurality of electrode stripes, wherein the electrode stripes of the first electrode are oriented perpendicular to the electrode stripes of the second electrode. As outlined above, at each crossing point of electrode stripes of the first electrode and an electrode stripe of the second electrode, a pixel is formed which may be read out independently.

The detector may further comprise appropriate reading electronics, such as a reading electronics adapted to contact one of the electrode stripes of the first electrode and to contact one of the electrode stripes of the second electrode and to measure a current through the stripes and/or to measure a voltage at the respective stripes. In order to read out the pixels, a sequential reading scheme may be chosen and/or a multiplexing scheme. Thus, as an example, all pixels within one row may be read out simultaneously, before switching to the next row of the matrix, thereby sequentially reading out all pixel rows. Alternatively, a row multiplexing be chosen, reading out all pixels of one column spontaneously, before switching to the next column. However, other readout schemes are possible, such as readout schemes using a plurality of transistors. Generally, passive matrix and/or active matrix readout schemes may be used. As an example of read-out schemes which may be used, reference may be made to US 2007/0080925 A1. Other readout schemes are feasible.

For potential electrode materials, reference may be made to WO 2012/110924 A1 and to US provisional applications number 61/739,173 and 61/749,964. Other embodiments are possible. Specifically, at least one of the first electrode and the second electrode may comprise an electrically conductive polymer. Specifically, a transparent electrically conductive polymer may be used. For potential embodiments of electrically conductive polymers, reference may be made to the named documents.

It shall be noted, however, that any other type of optical sensors, preferably transparent optical sensors, having a plurality of pixels, may be used for the present invention.

In a further aspect of the present invention, a detector system for determining a position of at least one object is disclosed. The detector system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments described above and/or as disclosed in one or more of the embodiments disclosed in further detail below.

The detector system further comprises at least one beacon device adapted to direct at least one light beam towards the detector. As used herein and as will be disclosed in further detail below, a beacon device generally refers to an arbitrary device adapted to direct at least one light beam towards the detector. The beacon device may fully or partially be embodied as an active beacon device, comprising at least one illumination source for generating the light beam. Additionally or alternatively, the beacon device may fully or partially be embodied as a passive beacon device comprising at least one reflective element adapted to reflect a primary light beam generated independently from the beacon device towards the detector.

The beacon device is at least one of attachable to the object, holdable by the object and integratable into the object. Thus, the beacon device may be attached to the object by an arbitrary attachment means, such as one or more connecting elements. Additionally or alternatively, the object may be adapted to hold the beacon device, such as by one or more appropriate holding means. Additionally or alternatively, again, the beacon device may fully or

partially be integrated into the object and, thus, may form part of the object or even may form the object.

Generally, with regard to potential embodiments of the beacon device, reference may be made to one or more of US provisional applications 61/739,173, filed on December 19, 2012, and 61/749,964, filed on January 8, 2013. Still, other embodiments are feasible.

As outlined above, the beacon device may fully or partially be embodied as an active beacon device and may comprise at least one illumination source. Thus, as an example, the beacon device may comprise a generally arbitrary illumination source, such as an illumination source selected from the group consisting of a light-emitting diode (LED), a light bulb, an incandescent lamp and a fluorescent lamp. Other embodiments are feasible.

Additionally or alternatively, as outlined above, the beacon device may fully or partially be embodied as a passive beacon device and may comprise at least one reflective device adapted to reflect a primary light beam generated by an illumination source independent from the object. Thus, in addition or alternatively to generating the light beam, the beacon device may be adapted to reflect a primary light beam towards the detector.

The detector system may comprise one, two, three or more beacon devices. Thus, generally, in case the object is a rigid object which, at least on a microscope scale, thus not change its shape, preferably, at least two beacon devices may be used. In case the object is fully or partially flexible or is adapted to fully or partially change its shape, preferably, three or more beacon devices may be used. Generally, the number of beacon devices may be adapted to the degree of flexibility of the object. Preferably, the detector system comprises at least three beacon devices.

The object generally may be a living or non-living object. The detector system even may comprise the at least one object, the object thereby forming part of the detector system.

Preferably, however, the object may move independently from the detector, in at least one spatial dimension.

The object generally may be an arbitrary object. In one embodiment, the object may be a rigid object. Other embodiments are feasible, such as embodiments in which the object is a non-rigid object or an object which may change its shape.

As will be outlined in further detail below, the present invention may specifically be used for tracking positions and/or motions of a person, such as for the purpose of controlling machines, gaming or simulation of sports. In this or other embodiments, specifically, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat; an article of clothing; a hat; a shoe.

In a further aspect of the present invention, a human-machine interface for exchanging at least one item of information between a user and a machine is disclosed. The human-machine interface comprises at least one detector system according to the present invention, such as to one or more of the embodiments disclosed above and/or according to one or more of the
5 embodiments disclosed in further detail below. The beacon devices are adapted to be at least one of directly or indirectly attached to the user and held by the user. The human-machine interface is designed to determine at least one position of the user by means of the detector system. The human-machine interface further is designed to assign to the position at least one item of information.

10 In a further aspect of the present invention, an entertainment device for carrying out at least one entertainment function is disclosed. The entertainment device comprises at least one human-machine interface according to the present invention. The entertainment device further is designed to enable at least one item of information to be input by a player by means of the
15 human-machine interface. The entertainment device further is designed to vary the entertainment function in accordance with the information.

In a further aspect of the present invention, a tracking system for tracking a position of at least one movable object is disclosed. The tracking system comprises at least one detector system
20 according to the present invention, such as to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed in further detail below. The tracking system further comprises at least one track controller, wherein the track controller is adapted to track a series of positions of the object at specific points in time.

25 In a further aspect of the present invention, a method for determining a position of at least one object is disclosed. The method comprises the following steps, which may be performed in the given order or in a different order. Further, two or more or even all of the method steps may be performed simultaneously and/or overlapping in time. Further, one, two or more or even all of the method steps may be performed repeatedly. The method may further comprise additional
30 method steps. The method comprises the following method steps:

- at least one detection step, wherein at least one light beam traveling from the object to a detector is detected by at least one optical sensor of the detector, the at least one optical sensor having a matrix of pixels; and
- at least one evaluation step, wherein a number N of pixels of the optical sensor is
35 determined which are illuminated by the light beam, wherein at least one longitudinal coordinate of the object is determined by using the number N of pixels which are illuminated by the light beam.

40 The method preferably may be performed by using at least one detector according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed in further detail below. Thus, for preferred optional embodiments of the method, reference may be made to the disclosure of the detector. The method may further be performed by using the detector system, the human-

machine interface, the entertainment device or the tracking system according to the present invention. Other embodiments are feasible.

The method specifically may be performed in such a way that the optical sensor generates at least one signal indicating an intensity of illumination for each of the pixels. Thus, for each of the pixels, an analog and/or digital intensity signal may be generated. In case a digital intensity signal is generated directly or e.g. after analog-digital conversion, the digital signal for each pixel may be a one-bit signal or, preferably, may be a signal having an information depth of more than one bit, such as 4 bit, 8 bit, 16 bit or a different number of bits.

In the evaluation step, for each of the pixels, the signal of the respective pixel may be compared to at least one threshold in order to determine whether the pixel is an illuminated pixel or not.

As outlined above, the threshold may be a predetermined threshold or may be a variable threshold which may be determined according to at least one predetermined algorithm.

In the evaluation step, at least one pixel having the highest illumination out of the pixels is determined by comparing the signals of the pixels. Thus, one or more of the pixels may be determined which have the highest illumination out of the pixels of the matrix.

The knowledge about the one or more pixels having the highest illumination may be used in various ways. Thus, as an example, this information may be used for determining the above-mentioned threshold. As an example, the threshold may be chosen as a fraction of the signal of the at least one pixel having the highest illumination. As outlined above, as an example, the threshold may be chosen by multiplying the signal of the at least one pixel having the highest illumination with a factor of $1/e^2$.

The longitudinal coordinate of the object may be determined by using a predetermined relationship between the number N of pixels which are illuminated by the light beam and the longitudinal coordinate. As outlined above, the predetermined relationship may be an empirical relationship and/or an analytical relationship. As an example, the predetermined relationship may be based on the assumption of the light beam being a Gaussian light beam. Thus, as explained above with respect to the detector, the predetermined relationship may be:

$$N \sim \pi \cdot w_0^2 \cdot \left(1 + \left(\frac{z}{z_0}\right)^2\right),$$

wherein z is the longitudinal coordinate,

wherein w_0 is a minimum beam radius of the light beam when propagating in space,

wherein z_0 is a Rayleigh-length of the light beam with $z_0 = \pi \cdot w_0^2 / \lambda$, λ being the wavelength of the light beam.

Again, preferably, the matrix of pixels may be a two-dimensional matrix. More preferably, the matrix of pixels may be a rectangular matrix.

5 As for the detector, the detector may comprise one optical sensor or, preferably, a plurality of the optical sensors. The optical sensors may be stacked along an optical axis of the detector.

The detector may comprise n optical sensors. Therein, the number N_i of pixels which are illuminated by the light beam may be determined for each of the optical sensors, wherein $i \in \{1, n\}$ denotes the respective optical sensor.

10

The number N_i of pixels which are illuminated by the light beam for each optical sensor may be compared with at least one neighboring optical sensor, thereby resolving an ambiguity in the longitudinal coordinate of the object. Further, additionally or alternatively, the sensor signals of the optical sensors may be normalized for a power of the light beam.

15

In a further aspect of the present invention, a use of the detector according to the present invention, such as to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed in further detail below, is disclosed, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an
20 entertainment application; a security application; a safety application; a human-machine interface application; a tracking application; a photography application, such as an application for digital photography for arts, documentation or technical purposes; a use in combination with at least one time-of-flight detector.

25 Thus, generally, the detector according to the present invention may be applied in various fields of uses. Specifically, the detector may be applied for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a human-machine interface application; a tracking application; a photography application; a mapping application for generating maps of at least one space, such
30 as at least one space selected from the group of a room, a building and a street; a mobile application; a webcam; an audio device; a dolby surround audio system; a computer peripheral device; a gaming application; a camera or video application; a security application; a surveillance application; an automotive application; a transport application; a medical application; a sports' application; a machine vision application; a vehicle application; an airplane
35 application; a ship application; a spacecraft application; a building application; a construction application; a cartography application; a manufacturing application; a use in combination with at least one time-of-flight detector. Additionally or alternatively, applications in local and/or global positioning systems may be named, especially landmark-based positioning and/or navigation, specifically for use in cars or other vehicles (such as trains, motorcycles, bicycles, trucks for
40 cargo transportation), robots or for use by pedestrians. Further, indoor positioning systems may be named as potential applications, such as for household applications and/or for robots used in manufacturing technology.

Thus, as for the optical detectors and devices disclosed in WO 2012/110924 A1 or in US provisional applications 61/739,173, filed on December 19, 2012, 61/749,964, filed on January 8, 2013, and 61/867,169, filed on August 19, 2013, and international patent application PCT/IB2013/061095, filed on December 18, 2013, the detector, the detector system, the
5 human-machine interface, the entertainment device, the tracking system or the camera according to the present invention (in the following simply referred to as “the devices according to the present invention” may be used for a plurality of application purposes, such as one or more of the purposes disclosed in further detail in the following.

Thus, firstly, the devices according to the present invention may be used in mobile phones, tablet computers, laptops, smart panels or other stationary or mobile computer or communication applications. Thus, the devices according to the present invention may be combined with at least one active light source, such as a light source emitting light in the visible range or infrared spectral range, in order to enhance performance. Thus, as an example, the
15 devices according to the present invention may be used as cameras and/or sensors, such as in combination with mobile software for scanning environment, objects and living beings. The devices according to the present invention may even be combined with 2D cameras, such as conventional cameras, in order to increase imaging effects. The devices according to the present invention may further be used for surveillance and/or for recording purposes or as input
20 devices to control mobile devices, especially in combination with voice and/or gesture recognition. Thus, specifically, the devices according to the present invention acting as human-machine interfaces, also referred to as input devices, may be used in mobile applications, such as for controlling other electronic devices or components via the mobile device, such as the mobile phone. As an example, the mobile application including at least one device according to
25 the present invention may be used for controlling a television set, a game console, a music player or music device or other entertainment devices.

Further, the devices according to the present invention may be used in webcams or other peripheral devices for computing applications. Thus, as an example, the devices according to
30 the present invention may be used in combination with software for imaging, recording, surveillance, scanning or motion detection. As outlined in the context of the human-machine interface and/or the entertainment device, the devices according to the present invention are particularly useful for giving commands by facial expressions and/or body expressions. The devices according to the present invention can be combined with other input generating devices
35 like e.g. mouse, keyboard, touchpad, microphone etc. Further, the devices according to the present invention may be used in applications for gaming, such as by using a webcam. Further, the devices according to the present invention may be used in virtual training applications and/or video conferences

40 Further, the devices according to the present invention may be used in mobile audio devices, television devices and gaming devices, as partially explained above. Specifically, the devices according to the present invention may be used as controls or control devices for electronic devices, entertainment devices or the like. Further, the devices according to the present

invention may be used for eye detection or eye tracking, such as in 2D- and 3D-display techniques, especially with transparent displays for augmented reality applications and/or for recognizing whether a display is being looked at and/or from which perspective a display is being looked at.

5

Further, the devices according to the present invention may be used in or as digital cameras such as DSC cameras and/or in or as reflex cameras such as SLR cameras. For these applications, reference may be made to the use of the devices according to the present invention in mobile applications such as mobile phones, as disclosed above.

10

Further, the devices according to the present invention may be used for security or surveillance applications. Thus, as an example, at least one device according to the present invention can be combined with one or more digital and/or analog electronics that will give a signal if an object is within or outside a predetermined area (e.g. for surveillance applications in banks or

15

museums). Specifically, the devices according to the present invention may be used for optical encryption. Detection by using at least one device according to the present invention can be combined with other detection devices to complement wavelengths, such as with IR, x-ray, UV-VIS, radar or ultrasound detectors. The devices according to the present invention may further be combined with an active infrared light source to allow detection in low light surroundings. The

20

devices according to the present invention are generally advantageous as compared to active detector systems, specifically since the devices according to the present invention avoid actively sending signals which may be detected by third parties, as is the case e.g. in radar applications, ultrasound applications, LIDAR or similar active detector devices. Thus, generally, the devices according to the present invention may be used for an unrecognized and undetectable tracking

25

of moving objects. Additionally, the devices according to the present invention generally are less prone to manipulations and irritations as compared to conventional devices.

Further, given the ease and accuracy of 3D detection by using the devices according to the present invention, the devices according to the present invention generally may be used for facial, body and person recognition and identification. Therein, the devices according to the present invention may be combined with other detection means for identification or personalization purposes such as passwords, finger prints, iris detection, voice recognition or other means. Thus, generally, the devices according to the present invention may be used in security devices and other personalized applications.

35

Further, the devices according to the present invention may be used as 3D barcode readers for product identification.

In addition to the security and surveillance applications mentioned above, the devices according to the present invention generally can be used for surveillance and monitoring of spaces and areas. Thus, the devices according to the present invention may be used for surveying and monitoring spaces and areas and, as an example, for triggering or executing alarms in case prohibited areas are violated. Thus, generally, the devices according to the present invention

40

may be used for surveillance purposes in building surveillance or museums, optionally in combination with other types of sensors, such as in combination with motion or heat sensors, in combination with image intensifiers or image enhancement devices and/or photomultipliers.

- 5 Further, the devices according to the present invention may advantageously be applied in camera applications such as video and camcorder applications. Thus, the devices according to the present invention may be used for motion capture and 3D-movie recording. Therein, the devices according to the present invention generally provide a large number of advantages over conventional optical devices. Thus, the devices according to the present invention generally
- 10 require a lower complexity with regard to optical components. Thus, as an example, the number of lenses may be reduced as compared to conventional optical devices, such as by providing the devices according to the present invention having one lens only. Due to the reduced complexity, very compact devices are possible, such as for mobile use. Conventional optical systems having two or more lenses with high quality generally are voluminous, such as due to
- 15 the general need for voluminous beam-splitters. Further, the devices according to the present invention generally may be used for focus/autofocus devices, such as autofocus cameras. Further, the devices according to the present invention may also be used in optical microscopy, especially in confocal microscopy.
- 20 Further, the devices according to the present invention generally are applicable in the technical field of automotive technology and transport technology. Thus, as an example, the devices according to the present invention may be used as distance and surveillance sensors, such as for adaptive cruise control, emergency brake assist, lane departure warning, surround view, blind spot detection, rear cross traffic alert, and other automotive and traffic applications.
- 25 Further, the devices according to the present invention can also be used for velocity and/or acceleration measurements, such as by analyzing a first and second time-derivative of position information gained by using the detector according to the present invention. This feature generally may be applicable in automotive technology, transportation technology or general traffic technology. Applications in other fields of technology are feasible. A specific application in
- 30 an indoor positioning system may be the detection of positioning of passengers in transportation, more specifically to electronically control the use of safety systems such as airbags. The use of an airbag may be prevented in case the passenger is located as such, that the use of an airbag will cause a severe injury.
- 35 In these or other applications, generally, the devices according to the present invention may be used as standalone devices or in combination with other sensor devices, such as in combination with radar and/or ultrasonic devices. Specifically, the devices according to the present invention may be used for autonomous driving and safety issues. Further, in these applications, the devices according to the present invention may be used in combination with
- 40 infrared sensors, radar sensors, which are sonic sensors, two-dimensional cameras or other types of sensors. In these applications, the generally passive nature of the devices according to the present invention is advantageous. Thus, since the devices according to the present invention generally do not require emitting signals, the risk of interference of active sensor

signals with other signal sources may be avoided. The devices according to the present invention specifically may be used in combination with recognition software, such as standard image recognition software. Thus, signals and data as provided by the devices according to the present invention typically are readily processable and, therefore, generally require lower calculation power than established stereovision systems such as LIDAR. Given the low space demand, the devices according to the present invention such as cameras may be placed at virtually any place in a vehicle, such as on a window screen, on a front hood, on bumpers, on lights, on mirrors or other places the like. Various detectors according to the present invention such as one or more detectors based on the effect disclosed within the present invention can be combined, such as in order to allow autonomously driving vehicles or in order to increase the performance of active safety concepts. Thus, various devices according to the present invention may be combined with one or more other devices according to the present invention and/or conventional sensors, such as in the windows like rear window, side window or front window, on the bumpers or on the lights.

A combination of at least one device according to the present invention such as at least one detector according to the present invention with one or more rain detection sensors is also possible. This is due to the fact that the devices according to the present invention generally are advantageous over conventional sensor techniques such as radar, specifically during heavy rain. A combination of at least one device according to the present invention with at least one conventional sensing technique such as radar may allow for a software to pick the right combination of signals according to the weather conditions.

Further, the devices according to the present invention generally may be used as break assist and/or parking assist and/or for speed measurements. Speed measurements can be integrated in the vehicle or may be used outside the vehicle, such as in order to measure the speed of other cars in traffic control. Further, the devices according to the present invention may be used for detecting free parking spaces in parking lots.

Further, the devices according to the present invention may be used in the fields of medical systems and sports. Thus, in the field of medical technology, surgery robotics, e.g. for use in endoscopes, may be named, since, as outlined above, the devices according to the present invention may require a low volume only and may be integrated into other devices. Specifically, the devices according to the present invention having one lens, at most, may be used for capturing 3D information in medical devices such as in endoscopes. Further, the devices according to the present invention may be combined with an appropriate monitoring software, in order to enable tracking and analysis of movements. These applications are specifically valuable e.g. in medical treatments and long-distance diagnosis and tele-medicine.

Further, the devices according to the present invention may be applied in the field of sports and exercising, such as for training, remote instructions or competition purposes. Specifically, the devices according to the present invention may be applied in the fields of dancing, aerobic, football, soccer, basketball, baseball, cricket, hockey, track and field, swimming, polo, handball,

volleyball, rugby, sumo, judo, fencing, boxing etc. The devices according to the present invention can be used to detect the position of a ball, a bat, a sword, motions, etc., both in sports and in games, such as to monitor the game, support the referee or for judgment, specifically automatic judgment, of specific situations in sports, such as for judging whether a point or a goal actually was made.

The devices according to the present invention further may be used in rehabilitation and physiotherapy, in order to encourage training and/or in order to survey and correct movements. Therein, the devices according to the present invention may also be applied for distance diagnostics.

Further, the devices according to the present invention may be applied in the field of machine vision. Thus, one or more of the devices according to the present invention may be used e.g. as a passive controlling unit for autonomous driving and or working of robots. In combination with moving robots, the devices according to the present invention may allow for autonomous movement and/or autonomous detection of failures in parts. The devices according to the present invention may also be used for manufacturing and safety surveillance, such as in order to avoid accidents including but not limited to collisions between robots, production parts and living beings. In robotics, the safe and direct interaction of humans and robots is often an issue, as robots may severely injure humans when they are not recognized. Devices according to the present invention may help robots to position objects and humans better and faster and allow a safe interaction. Given the passive nature of the devices according to the present invention, the devices according to the present invention may be advantageous over active devices and/or may be used complementary to existing solutions like radar, ultrasound, 2D cameras, IR detection etc. One particular advantage of the devices according to the present invention is the low likelihood of signal interference. Therefore multiple sensors can work at the same time in the same environment, without the risk of signal interference. Thus, the devices according to the present invention generally may be useful in highly automated production environments like e.g. but not limited to automotive, mining, steel, etc. The devices according to the present invention can also be used for quality control in production, e.g. in combination with other sensors like 2-D imaging, radar, ultrasound, IR etc., such as for quality control or other purposes. Further, the devices according to the present invention may be used for assessment of surface quality, such as for surveying the surface evenness of a product or the adherence to specified dimensions, from the range of micrometers to the range of meters. Other quality control applications are feasible. In a manufacturing environment, the devices according to the present invention are especially useful for processing natural products such as food or wood, with a complex 3-dimensional structure to avoid large amounts of waste material. Further, devices according to the present invention may be used in to monitor the filling level of tanks, silos etc.

Further, the devices according to the present invention may be used in the polls, airplanes, ships, spacecraft and other traffic applications. Thus, besides the applications mentioned above in the context of traffic applications, passive tracking systems for aircraft, vehicles and the like may be named. The use of at least one device according to the present invention, such as at

least one detector according to the present invention, for monitoring the speed and/or the direction of moving objects is feasible. Specifically, the tracking of fast moving objects on land, sea and in the air including space may be named. The at least one device according to the present invention, such as the at least one detector according to the present invention, specifically may be mounted on a still-standing and/or on a moving device. An output signal of the at least one device according to the present invention can be combined e.g. with a guiding mechanism for autonomous or guided movement of another object. Thus, applications for avoiding collisions or for enabling collisions between the tracked and the steered object are feasible. The devices according to the present invention generally are useful and advantageous due to the low calculation power required, the instant response and due to the passive nature of the detection system which generally is more difficult to detect and to disturb as compared to active systems, like e.g. radar. The devices according to the present invention are particularly useful but not limited to e.g. speed control and air traffic control devices.

The devices according to the present invention generally may be used in passive applications. Passive applications include guidance for ships in harbors or in dangerous areas, and for aircraft at landing or starting. Wherein, fixed, known active targets may be used for precise guidance. The same can be used for vehicles driving in dangerous but well defined routes, such as mining vehicles.

Further, as outlined above, the devices according to the present invention may be used in the field of gaming. Thus, the devices according to the present invention can be passive for use with multiple objects of the same or of different size, color, shape, etc., such as for movement detection in combination with software that incorporates the movement into its content. In particular, applications are feasible in implementing movements into graphical output. Further, applications of the devices according to the present invention for giving commands are feasible, such as by using one or more of the devices according to the present invention for gesture or facial recognition. The devices according to the present invention may be combined with an active system in order to work under e.g. low light conditions or in other situations in which enhancement of the surrounding conditions is required. Additionally or alternatively, a combination of one or more the devices according to the present invention with one or more IR or VIS light sources is possible. A combination of a detector according to the present invention with special devices is also possible, which can be distinguished easily by the system and its software, e.g. and not limited to, a special color, shape, relative position to other devices, speed of movement, light, frequency used to modulate light sources on the device, surface properties, material used, reflection properties, transparency degree, absorption characteristics, etc. The device can, amongst other possibilities, resemble a stick, a racquet, a club, a gun, a knife, a wheel, a ring, a steering wheel, a bottle, a ball, a glass, a vase, a spoon, a fork, a cube, a dice, a figure, a puppet, a teddy, a beaker, a pedal, a switch, a glove, jewelry, a musical instrument or an auxiliary device for playing a musical instrument, such as a plectrum, a drumstick or the like. Other options are feasible.

Further, the devices according to the present invention generally may be used in the field of building, construction and cartography. Thus, generally, one or more devices according to the present invention may be used in order to measure and/or monitor environmental areas, e.g. countryside or buildings. Therein, one or more the devices according to the present invention
5 may be combined with other methods and devices or can be used solely in order to monitor progress and accuracy of building projects, changing objects, houses, etc. the devices according to the present invention can be used for generating three-dimensional models of scanned environments, in order to construct maps of rooms, streets, houses, communities or landscapes, both from ground or from air. Potential fields of application may be construction,
10 cartography, real estate management, land surveying or the like.

One or more devices according to the present invention can further be used for scanning of objects, such as in combination with CAD or similar software, such as for additive manufacturing and/or 3D printing. Therein, use may be made of the high dimensional accuracy
15 of the devices according to the present invention, e.g. in x-, y- or z- direction or in any arbitrary combination of these directions, such as simultaneously. Further, the devices according to the present invention may be used in inspections and maintenance, such as pipeline inspection gauges.

As outlined above, the devices according to the present invention may further be used in manufacturing, quality control or identification applications, such as in product identification or size identification (such as for finding an optimal place or package, for reducing waste etc.). Further, the devices according to the present invention may be used in logistics applications. Thus, the devices according to the present invention may be used for optimized loading or
20 packing containers or vehicles. Further, the devices according to the present invention may be used for monitoring or controlling of surface damages in the field of manufacturing, for monitoring or controlling rental objects such as rental vehicles, and/or for insurance applications, such as for assessment of damages. Further, the devices according to the present invention may be used for identifying a size of material, object or tools, such as for optimal
25 material handling, especially in combination with robots. Further, the devices according to the present invention may be used for process control in production, e.g. for observing filling level of tanks. Further, the devices according to the present invention may be used for maintenance of production assets like, but not limited to, tanks, pipes, reactors, tools etc. Further, the devices according to the present invention may be used for analyzing 3D-quality marks. Further, the
30 devices according to the present invention may be used in manufacturing tailor-made goods such as tooth inlays, dental braces, prosthesis, clothes or the like. The devices according to the present invention may also be combined with one or more 3D-printers for rapid prototyping, 3D-copying or the like. Further, the devices according to the present invention may be used for detecting the shape of one or more articles, such as for anti-product piracy and for anti-
35 counterfeiting purposes.
40

Thus, specifically, the present application may be applied in the field of photography. Thus, the detector may be part of a photographic device, specifically of a digital camera. Specifically, the

detector may be used for 3D photography, specifically for digital 3D photography. Thus, the detector may form a digital 3D camera or may be part of a digital 3D camera. As used herein, the term photography generally refers to the technology of acquiring image information of at least one object. As further used herein, a camera generally is a device adapted for performing photography. As further used herein, the term digital photography generally refers to the technology of acquiring image information of at least one object by using a plurality of light-sensitive elements adapted to generate electrical signals indicating an intensity and/or color of illumination, preferably digital electrical signals. As further used herein, the term 3D photography generally refers to the technology of acquiring image information of at least one object in three spatial dimensions. Accordingly, a 3D camera is a device adapted for performing 3D photography. The camera generally may be adapted for acquiring a single image, such as a single 3D image, or may be adapted for acquiring a plurality of images, such as a sequence of images. Thus, the camera may also be a video camera adapted for video applications, such as for acquiring digital video sequences.

Thus, generally, the present invention further refers to a camera, specifically a digital camera, more specifically a 3D camera or digital 3D camera, for imaging at least one object. As outlined above, the term imaging, as used herein, generally refers to acquiring image information of at least one object. The camera comprises at least one detector according to the present invention. The camera, as outlined above, may be adapted for acquiring a single image or for acquiring a plurality of images, such as image sequence, preferably for acquiring digital video sequences. Thus, as an example, the camera may be or may comprise a video camera. In the latter case, the camera preferably comprises a data memory for storing the image sequence.

As used within the present invention, the expression "position" generally refers to at least one item of information regarding one or more of an absolute position and an orientation of one or more points of the object. Thus, specifically, the position may be determined in a coordinate system of the detector, such as in a Cartesian coordinate system. Additionally or alternatively, however, other types of coordinate systems may be used, such as polar coordinate systems and/or spherical coordinate systems.

As outlined above and as will be outlined in further detail below, the present invention preferably may be applied in the field of human-machine interfaces, in the field of sports and/or in the field of computer games. Thus, preferably, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat; an article of clothing; a hat; a shoe. Other embodiments are feasible.

As used herein, the object generally may be an arbitrary object, chosen from a living object and a non-living object. Thus, as an example, the at least one object may comprise one or more articles and/or one or more parts of an article. Additionally or alternatively, the object may be or may comprise one or more living beings and/or one or more parts thereof, such as one or more body parts of a human being, e.g. a user, and/or an animal.

With regard to the coordinate system for determining the position of the object, which may be a coordinate system of the detector, the detector may constitute a coordinate system in which an optical axis of the detector forms the z-axis and in which, additionally, an x-axis and a y-axis may be provided which are perpendicular to the z-axis and which are perpendicular to each other. As an example, the detector and/or a part of the detector may rest at a specific point in this coordinate system, such as at the origin of this coordinate system. In this coordinate system, a direction parallel or antiparallel to the z-axis may be regarded as a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. An arbitrary direction perpendicular to the longitudinal direction may be considered a transversal direction, and an x- and/or y-coordinate may be considered a transversal coordinate.

Alternatively, other types of coordinate systems may be used. Thus, as an example, a polar coordinate system may be used in which the optical axis forms a z-axis and in which a distance from the z-axis and a polar angle may be used as additional coordinates. Again, a direction parallel or antiparallel to the z-axis may be considered a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. Any direction perpendicular to the z-axis may be considered a transversal direction, and the polar coordinate and/or the polar angle may be considered a transversal coordinate.

As used herein, a detector for determining a position of at least one object generally is a device adapted for providing at least one item of information on the position of the at least one object and/or a part thereof. Thus, the position may refer to an item of information fully describing the position of the object or a part thereof, preferably in the coordinate system of the detector, or may refer to a partial information, which only partially describes the position. The detector generally may be a device adapted for detecting light beams, such as the light beams traveling from the beacon devices towards the detector.

The evaluation device and the detector may fully or partially be integrated into a single device. Thus, generally, the evaluation device also may form part of the detector. Alternatively, the evaluation device and the detector may fully or partially be embodied as separate devices. The detector may comprise further components.

The detector may be a stationary device or a mobile device. Further, the detector may be a stand-alone device or may form part of another device, such as a computer, a vehicle or any other device. Further, the detector may be a hand-held device. Other embodiments of the detector are feasible.

As used herein, an optical sensor generally is a device which is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the optical sensor by the light beam. Preferably, as outlined above and as will be outlined in further detail below, the detector according to the present invention may comprise a plurality of optical sensors, preferably as a sensor stack.

The at least one optical sensor may comprise one or more photo detectors, preferably one or more organic photodetectors and, most preferably, one or more dye-sensitized organic solar cells (DSCs, also referred to as dye solar cells), such as one or more solid dye-sensitized organic solar cells (sDSCs). Thus, preferably, the detector may comprise one or more DSCs (such as one or more sDSCs) acting as the at least one optical sensor, preferably a stack of a plurality of DSCs (preferably a stack of a plurality of sDSCs) acting as the at least one optical sensor. Additionally or alternatively, the detector may comprise other types of optical sensors, as outlined in further detail above.

As outlined above, the detector according to the present invention specifically may comprise a plurality of the optical sensors, which are also referred to as pixelated sensors or pixelated optical sensors. Specifically, the detector may comprise a stack of the optical sensors, such as a stack of transparent optical sensors.

Thus, the detector may comprise at least one stack of the optical sensors, and the detector may be adapted to acquire a three-dimensional image of a scene within a field of view of the detector. The optical sensors of the stack may have identical spectral properties, such as identical or uniform absorption spectra. Alternatively, the optical sensors of the stack may have differing spectral properties. Thus, the stack may comprise at least one first optical sensor having a first spectral sensitivity and at least one second optical sensor having a second spectral sensitivity, wherein the first spectral sensitivity and the second spectral sensitivity are different. The stack specifically may comprise optical sensors having differing spectral properties in an alternating sequence. The detector may be adapted to acquire a multicolor three-dimensional image, preferably a full-color three-dimensional image, by evaluating sensor signals of the optical sensors having differing spectral properties.

Thus, generally, the pixelated sensors, specifically the transparent pixelated sensors, may be used to record images at different distances to the detector, such as at different distances to the at least one optional transfer device and, more specifically, to at least one lens of the detector. If more than one pixelated sensor is used, several images at different distances to the detector may be recorded simultaneously. Preferably the distances to the lens are as such, that different parts of the images are in focus. Thus, the images can be used in image-processing techniques known as focus stacking, z-stacking, focal plane merging. One application of these techniques is obtaining images with greater depth of field, which is especially helpful in imaging techniques with typically very shallow depth of field such as macro photography or optical microscopy. Another application is to obtain distance information using algorithms, convolution based algorithms such as depth from focus or depth from defocus. Another application is to optimize the images to obtain a greater artistic or scientific merit.

The detector having the plurality of pixelated sensors also may be used to record a light-field behind a lens or lens system of the detector, comparable to a plenoptic or light-field camera. Thus, specifically, the detector may be embodied as a light-field camera adapted for acquiring images in multiple focal planes, such as simultaneously. The term light-field, as used herein,

generally refers to the spatial light propagation of light inside the detector such as inside camera. The detector according to the present invention, specifically having a stack of optical sensors, may have the capability of directly recording a light-field within the detector or camera, such as behind a lens. The plurality of pixelated sensors may record images at different
5 distances from the lens. Using, e.g., convolution-based algorithms such as “depth from focus” or “depth from defocus”, the propagation direction, focus points, and spread of the light behind the lens can be modeled. From the modeled propagation of light behind the lens, images at various distances to the lens can be extracted, the depth of field can be optimized, pictures that are in focus at various distances can be extracted, or distances of objects can be calculated. Further
10 information may be extracted.

Once the light propagation inside the detector, such as behind a lens of the detector, is modeled and/or recorded, this knowledge of light propagation provides a large number of advantages. Thus, the light-field may be recorded in terms of beam parameters for one or more light beams
15 of a scene captured by the detector. As an example, for each light beam recorded, two or more beam parameters may be recorded, such as one or more Gaussian beam parameters, e.g. a beam waist, a minimum beam waist as a focal point, a Rayleigh length, or other beam parameters. Several representations of light beams may be used and beam parameters may be chosen accordingly.

This knowledge of light propagation, as an example, allows for slightly modifying the observer position after recording an image stack using image processing techniques. In a single image, an object may be hidden behind another object and is not visible. However, if the light scattered by the hidden object reaches the lens and through the lens one or more of the sensors, the
25 object may be made visible, by changing the distance to the lens and/or the image plane relative to the optical axis, or even using non-planar image planes. The change of the observer position may be compared to looking at a hologram, in which changing the observer position slightly changes the image.

The knowledge of light propagation inside the detector, such as by modeling the light propagation behind the lens, may further allow for storing the image information in a more compact way as compared to conventional technology of storing each image recorded by each individual optical sensor. The memory demand for storing all images of each optical sensor typically scales with the number of sensors times the number of pixels. The memory demand of
35 the light propagation scales with the number of modeled light beams times the number of parameters per light beam. Typical model functions for light beams may be Gaussians, Lorentzians, Bessel functions, especially spherical Bessel functions, other functions typically used for describing diffraction effects in physics, or typical spread functions used in depth from defocus techniques such as point spread functions, line spread functions or edge spread
40 functions.

The use of several pixelated sensors further allows for correcting lens errors in an image processing step after recording the images. Optical instruments often become expensive and

challenging in construction, when lens errors need to be corrected. These are especially problematic in microscopes and telescopes. In microscopes, a typical lens error is that rays of varying distance to the optical axis are distorted differently (spherical aberration). In telescopes, varying the focus may occur from differing temperatures in the atmosphere. Static errors such as spherical aberration or further errors from production may be corrected by determining the errors in a calibration step and then using a fixed image processing such as fixed set of pixels and sensor, or more involved processing techniques using light propagation information. In cases in which lens errors are strongly time-dependent, i.e. dependent on weather conditions in telescopes, the lens errors may be corrected by using the light propagation behind the lens, calculating extended depth of field images, using depth from focus techniques, and others.

As outlined above, the detector according to the present invention may further allow for color detection. For color detection in stacks of several pixelated sensors, the single stacks may have pixels that have different absorption properties, equal or similar to the so-called Bayer pattern, and color information may be obtained by interpolation techniques. A further method is to use sensors of alternating color, wherein different sensors in the stack may record different colors. In a Bayer pattern, color may be interpolated between same-color pixels. In a stack of sensors, the image information such as color and brightness, etc., can also be obtained by interpolation techniques.

The evaluation device may be or may comprise one or more integrated circuits, such as one or more application-specific integrated circuits (ASICs), and/or one or more data processing devices, such as one or more computers, preferably one or more microcomputers and/or microcontrollers. Additional components may be comprised, such as one or more preprocessing devices and/or data acquisition devices, such as one or more devices for receiving and/or preprocessing of the sensor signals, such as one or more AD-converters and/or one or more filters. Further, the evaluation device may comprise one or more measurement devices, such as one or more measurement devices for measuring electrical currents and/or electrical voltages. Thus, as an example, the evaluation device may comprise one or more measurement devices for measuring electrical currents through and/or electrical voltages of the pixels. Further, the evaluation device may comprise one or more data storage devices. Further, the evaluation device may comprise one or more interfaces, such as one or more wireless interfaces and/or one or more wire-bound interfaces.

The at least one evaluation device may be adapted to perform at least one computer program, such as at least one computer program adapted for performing or supporting one or more or even all of the method steps of the method according to the present invention. As an example, one or more algorithms may be implemented which, by using the sensor signals as input variables, may determine the position of the object.

The evaluation device can be connected to or may comprise at least one further data processing device that may be used for one or more of displaying, visualizing, analyzing, distributing, communicating or further processing of information, such as information obtained

by the optical sensor and/or by the evaluation device. The data processing device, as an example, may be connected or incorporate at least one of a display, a projector, a monitor, an LCD, a TFT, a loudspeaker, a multichannel sound system, an LED pattern, or a further visualization device. It may further be connected or incorporate at least one of a communication device or communication interface, a connector or a port, capable of sending encrypted or unencrypted information using one or more of email, text messages, telephone, bluetooth, Wi-Fi, infrared or internet interfaces, ports or connections. It may further be connected or incorporate at least one of a processor, a graphics processor, a CPU, an Open Multimedia Applications Platform (OMAP™), an integrated circuit, a system on a chip such as products from the Apple A series or the Samsung S3C2 series, a microcontroller or microprocessor, one or more memory blocks such as ROM, RAM, EEPROM, or flash memory, timing sources such as oscillators or phase-locked loops, counter-timers, real-time timers, or power-on reset generators, voltage regulators, power management circuits, or DMA controllers. Individual units may further be connected by buses such as AMBA buses.

The evaluation device and/or the data processing device may be connected by or have further external interfaces or ports such as one or more of serial or parallel interfaces or ports, USB, Centronics Port, FireWire, HDMI, Ethernet, Bluetooth, RFID, Wi-Fi, USART, or SPI, or analog interfaces or ports such as one or more of ADCs or DACs, or standardized interfaces or ports to further devices such as a 2D-camera device using an RGB-interface such as CameraLink. The evaluation device and/or the data processing device may further be connected by one or more of interprocessor interfaces or ports, FPGA-FPGA-interfaces, or serial or parallel interfaces ports. The evaluation device and the data processing device may further be connected to one or more of an optical disc drive, a CD-RW drive, a DVD+RW drive, a flash drive, a memory card, a disk drive, a hard disk drive, a solid state disk or a solid state hard disk.

The evaluation device and/or the data processing device may be connected by or have one or more further external connectors such as one or more of phone connectors, RCA connectors, VGA connectors, hermaphrodite connectors, USB connectors, HDMI connectors, 8P8C connectors, BCN connectors, IEC 60320 C14 connectors, optical fiber connectors, D-subminiature connectors, RF connectors, coaxial connectors, SCART connectors, XLR connectors, and/or may incorporate at least one suitable socket for one or more of these connectors.

Possible embodiments of a single device incorporating one or more of the detectors according to the present invention, the evaluation device or the data processing device, such as incorporating one or more of the optical sensor, optical systems, evaluation device, communication device, data processing device, interfaces, system on a chip, display devices, or further electronic devices, are: mobile phones, personal computers, tablet PCs, televisions, game consoles or further entertainment devices. In a further embodiment, the 3D-camera functionality which will be outlined in further detail below may be integrated in devices that are available with conventional 2D-digital cameras, without a noticeable difference in the housing or

appearance of the device, where the noticeable difference for the user may only be the functionality of obtaining and or processing 3D information.

Specifically, an embodiment incorporating the detector and/or a part thereof such as the evaluation device and/or the data processing device may be: a mobile phone incorporating a display device, a data processing device, the optical sensor, optionally the sensor optics, and the evaluation device, for the functionality of a 3D camera. The detector according to the present invention specifically may be suitable for integration in entertainment devices and/or communication devices such as a mobile phone.

A further embodiment of the present invention may be an incorporation of the detector or a part thereof such as the evaluation device and/or the data processing device in a device for use in automotive, for use in autonomous driving or for use in car safety systems such as Daimler's Intelligent Drive system, wherein, as an example, a device incorporating one or more of the optical sensors, optionally one or more optical systems, the evaluation device, optionally a communication device, optionally a data processing device, optionally one or more interfaces, optionally a system on a chip, optionally one or more display devices, or optionally further electronic devices may be part of a vehicle, a car, a truck, a train, a bicycle, an airplane, a ship, a motorcycle. In automotive applications, the integration of the device into the automotive design may necessitate the integration of the optical sensor, optionally optics, or device at minimal visibility from the exterior or interior. The detector or a part thereof such as the evaluation device and/or the data processing device may be especially suitable for such integration into automotive design.

As used herein, the term light generally refers to electromagnetic radiation in one or more of the visible spectral range, the ultraviolet spectral range and the infrared spectral range. Therein, the term visible spectral range generally refers to a spectral range of 380 nm to 780 nm. The term infrared spectral range generally refers to electromagnetic radiation in the range of 780 nm to 1 mm, preferably in the range of 780 nm to 3.0 micrometers. The term ultraviolet spectral range generally refers to electromagnetic radiation in the range of 1 nm to 380 nm, preferably in the range of 100 nm to 380 nm. Preferably, light as used within the present invention is visible light, i.e. light in the visible spectral range.

The term light beam generally refers to an amount of light emitted and/or reflected into a specific direction. Thus, the light beam may be a bundle of the light rays having a predetermined extension in a direction perpendicular to a direction of propagation of the light beam. Preferably, the light beams may be or may comprise one or more Gaussian light beams which may be characterized by one or more Gaussian beam parameters, such as one or more of a beam waist, a Rayleigh-length or any other beam parameter or combination of beam parameters suited to characterize a development of a beam diameter and/or a beam propagation in space.

As outlined above, preferably, specifically in case a plurality of optical sensors is provided, at least one of the optical sensors is a transparent optical sensor. Thus, in case a stack of the optical sensors is provided, preferably all optical sensors of the plurality and/or the stack or all optical sensors of the plurality and/or the stack but one optical sensor are transparent. As an example, in case a stack of optical sensors is provided, wherein the optical sensors are arranged along the optical axis of the detector, preferably all optical sensors but the last optical sensor furthest away from the object may be transparent optical sensors. The last optical sensor, i.e. the optical sensor on the side of the stack facing away from the object, may be a transparent optical sensor or an intransparent optical sensor. Exemplary embodiments will be given below.

As outlined above, the optical sensor preferably comprises an organic photodetector such as an organic solar cell and/or an sDSC. In order to provide a transparent optical sensor, the optical sensor may have two transparent electrodes. Thus, at least one first electrode and/or the at least one second electrode of the optical sensor preferably may fully or partially be transparent. In order to provide a transparent electrode, a transparent conductive oxide may be used (TCO), such as indium-doped tin oxide (ITO) and/or fluorine-doped tin oxide (FTO). Additionally or alternatively, metal layers may be used, such as thin layers of one or more metal selected from the group consisting of Al, Ag, Au and Pt, such as metal layers having a thickness of below 50 nm, preferably below 40 nm. In order to support connectivity, additionally or alternatively, conductive organic materials may be used, such as conductive polymers. Thus, as an example, one or more of the electrodes of the at least one optical sensor may comprise one or more transparent conductive polymers. As an example, one or more conductive polymer films having a surface conductivity of at least 0.00001 S/cm, at least 0.001 S/cm or at least 0.01 S/cm may be used, preferably of at least 0.1 S/cm or, more preferably, of at least 1 S/cm or even at least 10 S/cm or at least 100 S/cm. As an example, the at least one conductive polymer may be selected from the group consisting of: a poly-3,4-ethylenedioxythiophene (PEDOT), preferably PEDOT being electrically doped with at least one counter ion, more preferably PEDOT doped with sodium polystyrene sulfonate (PEDOT:PSS); a polyaniline (PANI); a polythiophene. Preferably, the conductive polymer provides an electric resistivity of 0.1 – 20 k Ω between the partial electrodes, preferably an electric resistivity of 0.5 – 5.0 k Ω and, more preferably, an electric resistivity of 1.0 – 3.0 k Ω . Generally, as used herein, a conductive material may be a material which has a specific electrical resistance of less than 10⁴, less than 10³, less than 10², or of less than 10 Ω m. Preferably, the conductive material has a specific electrical resistance of less than 10⁻¹, less than 10⁻², less than 10⁻³, less than 10⁻⁵, or less than 10⁻⁶ Ω m. Most preferably, the specific electrical resistance of the conductive material is less than 5 x 10⁻⁷ Ω m or is less than 1 x 10⁻⁷ Ω m, particularly in the range of the specific electrical resistance of aluminum.

Generally, the optical sensor may comprise an arbitrary optical sensor having a plurality of pixels arranged in a matrix. The optical sensor, as outlined above and for reasons of example only, may comprise at least one semiconductor detector, in particular an organic semiconductor detector comprising at least one organic material, preferably an organic solar cell and

particularly preferably a dye solar cell or dye-sensitized solar cell, in particular a solid dye solar cell or a solid dye-sensitized solar cell. Preferably, the optical sensor is or comprises a DSC or sDSC. Thus, preferably, the optical sensor comprises at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid p-semiconducting organic material, and at least one second electrode. In a preferred embodiment, the optical sensor comprises at least one DSC or, more preferably, at least one sDSC. As outlined above, preferably, the at least one optical sensor is a transparent optical sensor or comprises at least one transparent optical sensor. Thus, preferably, both the first electrode and the second electrode are transparent or, in case a plurality of optical sensors is provided, at least one of the optical sensors is designed such that both the first electrode and the second electrode are transparent. As outlined above, in case a stack of optical sensors is provided, preferably all optical sensors of the stack are transparent but the last optical sensor of the stack furthest away from the object. The last optical sensor may be transparent or intransparent. In the latter case, the last optical sensor may be designed such that its electrode facing towards the object is transparent, whereas its electrode facing away from the object may be intransparent.

As outlined above, the detector preferably has a plurality of optical sensors. More preferably, the plurality of optical sensors is stacked, such as along the optical axis of the detector. Thus, the optical sensors may form an optical sensor stack. The optical sensor stack preferably may be oriented such that the sensor regions of the optical sensors are oriented perpendicular to the optical axis. Thus, as an example, sensor areas or sensor surfaces of the single optical sensors may be oriented in parallel, wherein slight angular tolerances might be tolerable, such as angular tolerances of no more than 10° , preferably of no more than 5° .

In case stacked optical sensors are provided, the at least one transversal optical sensor preferably fully or partially may be located on a side of the stacked optical sensors facing towards the object. The at least one optional transversal optical sensor may as well be part of the sensor stack. Generally, any other arrangement is feasible. The optical sensors preferably are arranged such that the at least one light beam traveling from the object towards the detector illuminates all optical sensors, preferably sequentially. For the purpose of normalizing the sensor signals of the optical sensors, use may be made of the fact that, in case the single longitudinal sensor signals are generated by one and the same light beam, differences in the single longitudinal sensor signals are generally only due to differences in the cross-sections of the light beam at the location of the respective sensor regions of the single optical sensors. Thus, by comparing the single longitudinal sensor signals, information on a beam cross-section may be generated even if the overall power of the light beam is unknown.

Further, the above-mentioned stacking of the optical sensors and the generation of a plurality of longitudinal sensor signals by these stacked optical sensors may be used by the evaluation device in order to resolve an ambiguity in a known relationship between a beam cross-section of the light beam and the longitudinal coordinate of the beacon device. Thus, even if the beam properties of the light beam propagating from the beacon device to the detector are known fully

or partially, it is known that, in many beams, the beam cross-section narrows before reaching a focal point and, afterwards, widens again. Such is the case e.g. for Gaussian light beams. Thus, before and after a focal point in which the light beam has the narrowest beam cross-section, positions along the axis of propagation of the light beam occur in which the light beam has the same cross-section. Thus, as an example, at a distance z_0 before and after the focal point, the cross-section of the light beam is identical. Thus, in case only one optical sensor is used, a specific cross-section of the light beam might be determined, in case the overall power or intensity of the light beam is known. By using this information, the distance z_0 of the respective optical sensor from the focal point might be determined. However, in order to determine whether the respective optical sensor is located before or behind the focal point, additional information may be required, such as a history of movement of the object and/or the detector and/or information on whether the detector is located before or behind the focal point. In typical situations, this additional information may not be available. Therefore, by using a plurality of optical sensors, additional information may be gained in order to resolve the above-mentioned ambiguity. Thus, in case the evaluation device, by evaluating the longitudinal sensor signals, recognizes that the beam cross-section of the light beam on a first optical sensor is larger than the beam cross-section of the light beam on a second optical sensor, wherein the second optical sensor is located behind the first optical sensor, the evaluation device may determine that the light beam is still narrowing and that the location of the first optical sensor is situated before the focal point of the light beam. Contrarily, in case the beam cross-section of the light beam on the first optical sensor is smaller than the beam cross-section of the light beam on the second optical sensor, the evaluation device may determine that the light beam is widening and that the location of the second optical sensor is situated behind the focal point. Thus, generally, the evaluation device may be adapted to recognize whether the light beam widens or narrows, by comparing the longitudinal sensor signals of different longitudinal sensors.

The optical sensor stack preferably may comprise at least three optical sensors, more preferably at least four optical sensors, even more preferably at least five optical sensors or even at least six optical sensors. By tracking the longitudinal sensor signals of the optical sensors, even a beam profile of the light beam might be evaluated.

As used herein and as used in the following, the diameter of the light beam or, equivalently, a beam waist or twice the beam waist of the light beam might be used to characterize the beam cross-section of the light beam at a specific location. As outlined above, a known relationship might be used between the longitudinal position of the object and/or the respective beacon device, i.e. the beacon device emitting and/or reflecting the light beam, and the beam cross-section in order to determine the longitudinal coordinate of the beacon device by evaluating the at least one longitudinal sensor signal. As an example, as outlined above, a Gaussian relationship might be used, assuming that the light beam propagates at least approximately in a Gaussian manner. For this purpose, the light beam might be shaped appropriately, such as by using an illumination source generating a light beam having known propagation properties, such as a known Gaussian profile. For this purpose, the illumination source itself may generate the light beam having the known properties, which, for example, is the case for many types of

lasers, as the skilled person knows. Additionally or alternatively, the illumination source and/or the detector may have one or more transfer devices, such as one or more beam-shaping elements, such as one or more lenses and/or one or more diaphragms, in order to provide a light beam having known properties, as the skilled person will recognize. Thus, as an example, one or more transfer devices may be provided, such as one or more transfer devices having known beam-shaping properties. Additionally or alternatively, the illumination source and/or the detector, such as the at least one optional transfer device, may have one or more wavelength-selective elements, such as one or more filters, such as one or more filter elements for filtering out wavelengths outside an excitation maximum of the at least one transversal optical sensor and/or the at least one optical sensor.

Thus, generally, the evaluation device may be adapted to compare the beam cross-section and/or the diameter of the light beam with known beam properties of the light beam in order to determine the at least one item of information on the longitudinal position of the object, preferably from a known dependency of a beam diameter of the light beam on at least one propagation coordinate in a direction of propagation of the light beam and/or from a known Gaussian profile of the light beam.

As outlined above, the at least one optical sensor or pixelated sensor of the detector, as an example, may be or may comprise at least one organic optical sensor. As an example, the at least one optical sensor may be or may comprise at least one organic solar cell, such as at least one dye-sensitized solar cell (DSC), preferably at least one solid DSC or sDSC. Specifically, the at least one optical sensor may be or may comprise at least one optical sensor capable of showing an effect of the sensor signal being dependent on a photon density or flux of photons. In FiP sensors, given the same total power p of illumination, the sensor signal i is generally dependent on a flux F of photons, i.e. the number of photons per unit area. In other words, the at least one optical sensor may comprise at least one optical sensor which is defined as a FiP sensor, i.e. as an optical sensor capable of providing a sensor signal, the sensor having at least one sensor region, such as a plurality of sensor regions like e.g. pixels, wherein the sensor signal, given the same total power of illumination of the sensor region by the light beam, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area. This effect including potential embodiments of optical sensors exhibiting this effect (such as sDSCs) is disclosed in further detail in WO 2012/110924 A1, in US provisional applications 61/739,173, filed on December 19, 2012, 61/749,964, filed on January 8, 2013, and 61/867,169, filed on August 19, 2013, and international patent application PCT/IB2013/061095, filed on December 18, 2013. The embodiments of optical sensors exhibiting the FiP effect as disclosed in these prior art documents, which all are included herewith by reference, may also be used as optical sensors in the detector according to the present invention, besides the fact that the optical sensors or at least one of the optical sensors are pixelated. Thus, the optical sensors as used in one or more of the above-mentioned prior art documents, in a pixelated fashion, may also be used in the context of the present invention. A pixelation may simply be achieved by an appropriate patterning of the first and/or second

electrodes of these optical sensors. Thus, each of the pixels of the pixelated optical sensors exhibiting the above-mentioned FiP-effect may, by itself, form a FiP sensor.

Thus, the detector according to the present invention specifically may fully or partially be embodied as a pixelated FiP camera, i.e. as a camera in which the at least one optical sensor or, in case a plurality of optical sensors is provided, at least one of the optical sensors, are embodied as pixelated FiP sensors. In pixelated FiP-cameras, pictures may be recorded in a similar way as disclosed above in the setup of the light-field camera. Thus, the detector may comprise a stack of optical sensors, each optical sensor being embodied as a pixelated FiP sensor. Pictures may be recorded at different distances from the lens. A depth can be calculated from these pictures using approaches such as depth-from-focus and/or depth-from-defocus.

The FiP measurement typically necessitates two or more FiP sensors such as organic solar cells exhibiting the FiP effect. The photon density on the different cells may vary as such, that a current ratio of at least 1/100 is obtained between a cell close to focus and a cell out of focus. If the ratio is closer to 1, the measurement may be imprecise.

The at least one evaluation device may specifically be embodied to compare signals generated by pixels of different optical sensors, the pixels being located on a line parallel to an optical axis of the detector. A light cone of the light beam might cover a single pixel in the focus region. In the out-of-focus region, only a small part of the light cone will cover the pixel. Thus, in a stack of pixelated FiP sensors, the signal of the pixel of the sensor being out of focus will generally be much smaller than the signal of the pixel of the sensor being in focus. Consequently, the signal ratio will improve. For a calculation of the distance between the object and the detector, more than two optical sensors may be used in order to further increase the precision.

Thus, generally, the at least one optical sensor may comprise at least one stack of optical sensors, each optical sensor having at least one sensor region and being capable of providing at least one sensor signal, wherein the sensor signal, given the same total power of illumination of the sensor region by the light beam, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area, wherein the evaluation device may be adapted to compare at least one sensor signal generated by at least one pixel of a first one of the optical sensors with at least one sensor signal generated by at least one pixel of a second one of the optical sensors, specifically for determining a distance between the object and the detector and/or a z-coordinate of the object. The evaluation device may further be adapted for evaluating the sensor signals of the pixels. Thus, one or more evaluation algorithms may be used. Additionally or alternatively, other means of evaluation may be used, such as by using one or more lookup tables, such as one or more lookup tables comprising FiP sensor signal values or ratios thereof and corresponding z-coordinates of the object and/or corresponding distances between the object and the detector. An analysis of several FiP-signals, taking into account the distance to the lens and/or a distance between the optical

sensors may also result in information regarding the light beam, such as the spread of the light beam and, thus, the conventional FiP-distance.

As outlined above, the present invention further relates to a human-machine interface for exchanging at least one item of information between a user and a machine. The human-machine interface as proposed may make use of the fact that the above-mentioned detector in one or more of the embodiments mentioned above or as mentioned in further detail below may be used by one or more users for providing information and/or commands to a machine. Thus, preferably, the human-machine interface may be used for inputting control commands.

Generally, as used herein, the at least one position of the user may imply one or more items of information on a position of the user as a whole and/or one of or more body parts of the user. Thus, preferably, the position of the user may imply one or more items of information on a position of the user as provided by the evaluation device of the detector. The user, a body part of the user or a plurality of body parts of the user may be regarded as one or more objects the position of which may be detected by the at least one detector device. Therein, precisely one detector may be provided, or a combination of a plurality of detectors may be provided. As an example, a plurality of detectors may be provided for determining positions of a plurality of body parts of the user and/or for determining a position of at least one body part of the user.

The detector according to the present invention, comprising the at least one optical sensor and the at least one evaluation device, may further be combined with one or more other types of sensors or detectors. Thus, the detector comprising the at least one optical sensor having the matrix of pixels (in the following also simply referred to as the pixelated optical sensor and/or the pixelated sensor) and the at least one evaluation device may further comprise at least one additional detector. The at least one additional detector may be adapted for detecting at least one parameter, such as at least one of: a parameter of a surrounding environment, such as a temperature and/or a brightness of a surrounding environment; a parameter regarding a position and/or orientation of the detector; a parameter specifying a state of the object to be detected, such as a position of the object, e.g. an absolute position of the object and/or an orientation of the object in space. Thus, generally, the principles of the present invention may be combined with other measurement principles in order to gain additional information and/or in order to verify measurement results or reduce measurement errors or noise.

Specifically, the detector according to the present invention may further comprise at least one time-of-flight (ToF) detector adapted for detecting at least one distance between the at least one object and the detector by performing at least one time-of-flight measurement. As used herein, a time-of-flight measurement generally refers to a measurement based on a time a signal needs for propagating between two objects or from one object to a second object and back. In the present case, the signal specifically may be one or more of an acoustic signal or an electromagnetic signal such as a light signal. A time-of-flight detector consequently refers to a detector adapted for performing a time-of-flight measurement. Time-of-flight measurements are well-known in various fields of technology such as in commercially available distance

measurement devices or in commercially available flow meters, such as ultrasonic flow meters. Time-of-flight detectors even may be embodied as time-of-flight cameras. These types of cameras are commercially available as range-imaging camera systems, capable of resolving distances between objects based on the known speed of light.

5 Presently available ToF detectors generally are based on the use of a pulsed signal, optionally in combination with one or more light sensors such as CMOS-sensors. A sensor signal produced by the light sensor may be integrated. The integration may start at two different points in time. The distance may be calculated from the relative signal intensity between the two
10 integration results.

Further, as outlined above, ToF cameras are known and may generally be used, also in the context of the present invention. These ToF cameras may contain pixelated light sensors. However, since each pixel generally has to allow for performing two integrations, the pixel
15 construction generally is more complex and the resolutions of commercially available ToF cameras is rather low (typically 200x200 pixels). Distances below ~40 cm and above several meters typically are difficult or impossible to detect. Furthermore, the periodicity of the pulses leads to ambiguous distances, as only the relative shift of the pulses within one period is measured.

20 ToF detectors, as standalone devices, typically suffer from a variety of shortcomings and technical challenges. Thus, in general, ToF detectors and, more specifically, ToF cameras suffer from rain and other transparent objects in the light path, since the pulses might be reflected too early, objects behind the raindrop are hidden, or in partial reflections the
25 integration will lead to erroneous results. Further, in order to avoid errors in the measurements and in order to allow for a clear distinction of the pulses, low light conditions are preferred for ToF-measurements. Bright light such as bright sunlight can make a ToF-measurement impossible. Further, the energy consumption of typical ToF cameras is rather high, since pulses must be bright enough to be back-reflected and still be detectable by the camera. The
30 brightness of the pulses, however, may be harmful for eyes or other sensors or may cause measurement errors when two or more ToF measurements interfere with each other. In summary, current ToF detectors and, specifically, current ToF-cameras suffer from several disadvantages such as low resolution, ambiguities in the distance measurement, limited range of use, limited light conditions, sensitivity towards transparent objects in the light path, sensitivity
35 towards weather conditions and high energy consumption. These technical challenges generally lower the aptitude of present ToF cameras for daily applications such as for safety applications in cars, cameras for daily use or human-machine-interfaces, specifically for use in gaming applications.

40 In combination with the detector according to the present invention, having the at least one optical sensor comprising the matrix of pixels and as well as the above-mentioned principle of evaluating the number of illuminated pixels, the advantages and capabilities of both systems may be combined in a fruitful way. Thus, the detector may provide advantages at bright light

conditions, while the ToF detector generally provides better results at low-light conditions. A combined device, i.e. a detector according to the present invention further including at least one ToF detector, therefore provides increased tolerance with regard to light conditions as compared to both single systems. This is especially important for safety applications, such as in cars or other vehicles.

Specifically, the detector may be designed to use at least one ToF measurement for correcting at least one measurement performed by using the detector according to the present invention and vice versa. Further, the ambiguity of a ToF measurement may be resolved by using the detector. A measurement using the pixelated detector specifically may be performed whenever an analysis of ToF measurements results in a likelihood of ambiguity. Additionally or alternatively, measurements using the pixelated detector may be performed continuously in order to extend the working range of the ToF detector into regions which are usually excluded due to the ambiguity of ToF measurements. Additionally or alternatively, the pixelated detector may cover a broader or an additional range to allow for a broader distance measurement region. The pixelated detector, specifically the pixelated camera, may further be used for determining one or more important regions for measurements to reduce energy consumption or to protect eyes. Thus the pixelated detector may be adapted for detecting one or more regions of interest. Additionally or alternatively, the pixelated detector may be used for determining a rough depth map of one or more objects within a scene captured by the detector, wherein the rough depth map may be refined in important regions by one or more ToF measurements. Further, the pixelated detector may be used to adjust the ToF detector, such as the ToF camera, to the required distance region. Thereby, a pulse length and/or a frequency of the ToF measurements may be pre-set, such as for removing or reducing the likelihood of ambiguities in the ToF measurements. Thus, generally, the pixelated detector may be used for providing an autofocus for the ToF detector, such as for the ToF camera.

As outlined above, a rough depth map may be recorded by the pixelated detector, such as the pixelated camera. Further, the rough depth map, containing depth information or z-information regarding one or more objects within a scene captured by the detector, may be refined by using one or more ToF measurements. The ToF measurements specifically may be performed only in important regions. Additionally or alternatively, the rough depth map may be used to adjust the ToF detector, specifically the ToF camera.

Further, the use of the pixelated detector in combination with the at least one ToF detector may solve the above-mentioned problem of the sensitivity of ToF detectors towards the nature of the object to be detected or towards obstacles or media within the light path between the detector and the object to be detected, such as the sensitivity towards rain or weather conditions. A combined pixelated/ToF measurement may be used to extract the important information from ToF signals, or measure complex objects with several transparent or semi-transparent layers. Thus, objects made of glass, crystals, liquid structures, phase transitions, liquid motions, etc. may be observed. Further, the combination of a pixelated detector and at least one ToF detector will still work in rainy weather, and the overall detector will generally be less dependent

on weather conditions. As an example, measurement results provided by the pixelated detector may be used to remove the errors provoked by rain from ToF measurement results, which specifically renders this combination useful for safety applications such as in cars or other vehicles.

5

The implementation of at least one ToF detector into the detector according to the present invention may be realized in various ways. Thus, the at least one pixelated detector and the at least one ToF detector may be arranged in a sequence, within the same light path. As an example, at least one transparent pixelated detector may be placed in front of at least one ToF detector. Additionally or alternatively, separate light paths or split light paths for the pixelated detector and the ToF detector may be used. Therein, as an example, light paths may be separated by one or more beam-splitting elements, such as one or more of the beam splitting elements listed above or listed in further detail below. As an example, a separation of beam paths by wavelength-selective elements may be performed. Thus, e.g., the ToF detector may make use of infrared light, whereas the pixelated detector may make use of light of a different wavelength. In this example, the infrared light for the ToF detector may be separated off by using a wavelength-selective beam splitting element such as a hot mirror. Additionally or alternatively, light beams used for the measurement using the pixelated detector and light beams used for the ToF measurement may be separated by one or more beam-splitting elements, such as one or more semitransparent mirrors, beam-splitter cubes, polarization beam splitters or combinations thereof. Further, the at least one pixelated detector and the at least one ToF detector may be placed next to each other in the same device, using distinct optical pathways. Various other setups are feasible.

25 The at least one optional ToF detector may be combined with basically any of the embodiments of the detector according to the present invention. Specifically, the at least one ToF detector which may be a single ToF detector or a ToF camera, may be combined with a single optical sensor or with a plurality of optical sensors such as a sensor stack. Further, the detector may also comprise one or more imaging devices such as one or more inorganic imaging devices like
30 CCD chips and/or CMOS chips, preferably one or more full-color CCD chips or full-color CMOS chips. Additionally or alternatively, the detector may further comprise one or more thermographic cameras.

As outlined above, the human-machine interface may comprise a plurality of beacon devices
35 which are adapted to be at least one of directly or indirectly attached to the user and held by the user. Thus, the beacon devices each may independently be attached to the user by any suitable means, such as by an appropriate fixing device. Additionally or alternatively, the user may hold and/or carry the at least one beacon device or one or more of the beacon devices in his or her hands and/or by wearing the at least one beacon device and/or a garment containing the
40 beacon device on a body part.

The beacon device generally may be an arbitrary device which may be detected by the at least one detector and/or which facilitates detection by the at least one detector. Thus, as outlined

above or as will be outlined in further detail below, the beacon device may be an active beacon device adapted for generating the at least one light beam to be detected by the detector, such as by having one or more illumination sources for generating the at least one light beam.

Additionally or alternatively, the beacon device may fully or partially be designed as a passive

5 beacon device, such as by providing one or more reflective elements adapted to reflect a light beam generated by a separate illumination source. The at least one beacon device may permanently or temporarily be attached to the user in a direct or indirect way and/or may be carried or held by the user. The attachment may take place by using one or more attachment means and/or by the user himself or herself, such as by the user holding the at least one
10 beacon device by hand and/or by the user wearing the beacon device.

Additionally or alternatively, the beacon devices may be at least one of attached to an object and integrated into an object held by the user, which, in the sense of the present invention, shall be included into the meaning of the option of the user holding the beacon devices. Thus, as will
15 be outlined in further detail below, the beacon devices may be attached to or integrated into a control element which may be part of the human-machine interface and which may be held or carried by the user, and of which the orientation may be recognized by the detector device.

Thus, generally, the present invention also refers to a detector system comprising at least one detector device according to the present invention and which, further, may comprise at least
20 one object, wherein the beacon devices are one of attached to the object, held by the object and integrated into the object. As an example, the object preferably may form a control element, the orientation of which may be recognized by a user. Thus, the detector system may be part of the human-machine interface as outlined above or as outlined in further detail below. As an example, the user may handle the control element in a specific way in order to transmit one or
25 more items of information to a machine, such as in order to transmit one or more commands to the machine.

Alternatively, the detector system may be used in other ways. Thus, as an example, the object of the detector system may be different from a user or a body part of the user and, as an
30 example, may be an object which moves independently from the user. As an example, the detector system may be used for controlling apparatuses and/or industrial processes, such as manufacturing processes and/or robotics processes. Thus, as an example, the object may be a machine and/or a machine part, such as a robot arm, the orientation of which may be detected by using the detector system.

35 The human-machine interface may be adapted in such a way that the detector device generates at least one item of information on the position of the user or of at least one body part of the user. Specifically in case a manner of attachment of the at least one beacon device to the user is known, by evaluating the position of the at least one beacon device, at least one item of
40 information on a position and/or an orientation of the user or of a body part of the user may be gained.

The beacon device preferably is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user. As outlined above, the beacon device may fully or partially be designed as an active beacon device. Thus, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be transmitted to the detector, preferably at least one light beam having known beam properties. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

The object, which may form part of the detector system, may generally have an arbitrary shape. Preferably, the object being part of the detector system, as outlined above, may be a control element which may be handled by a user, such as manually. As an example, the control element may be or may comprise at least one element selected from the group consisting of: a glove, a jacket, a hat, shoes, trousers and a suit; a stick that may be held by hand; a bat; a club; a racket; a cane; a toy, such as a toy gun. Thus, as an example, the detector system may be part of the human-machine interface and/or of the entertainment device.

As used herein, an entertainment device is a device which may serve the purpose of leisure and/or entertainment of one or more users, in the following also referred to as one or more players. As an example, the entertainment device may serve the purpose of gaming, preferably computer gaming. Thus, the entertainment device may be implemented into a computer, a computer network or a computer system or may comprise a computer, a computer network or a computer system which runs one or more gaming software programs.

The entertainment device comprises at least one human-machine interface according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed below. The entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface. The at least one item of information may be transmitted to and/or may be used by a controller and/or a computer of the entertainment device.

The at least one item of information preferably may comprise at least one command adapted for influencing the course of a game. Thus, as an example, the at least one item of information may include at least one item of information on at least one orientation of the player and/or of one or more body parts of the player, thereby allowing for the player to simulate a specific position and/or orientation and/or action required for gaming. As an example, one or more of the following movements may be simulated and communicated to a controller and/or a computer of the entertainment device: dancing; running; jumping; swinging of a racket; swinging of a bat; swinging of a club; pointing of an object towards another object, such as pointing of a toy gun towards a target.

The entertainment device as a part or as a whole, preferably a controller and/or a computer of the entertainment device, is designed to vary the entertainment function in accordance with the

information. Thus, as outlined above, a course of a game might be influenced in accordance with the at least one item of information. Thus, the entertainment device might include one or more controllers which might be separate from the evaluation device of the at least one detector and/or which might be fully or partially identical to the at least one evaluation device or which
5 might even include the at least one evaluation device. Preferably, the at least one controller might include one or more data processing devices, such as one or more computers and/or microcontrollers.

As further used herein, a tracking system is a device which is adapted to gather information on
10 a series of past positions of the at least one object and/or at least one part of the object. Additionally, the tracking system may be adapted to provide information on at least one predicted future position and/or orientation of the at least one object or the at least one part of the object. The tracking system may have at least one track controller, which may fully or partially be embodied as an electronic device, preferably as at least one data processing
15 device, more preferably as at least one computer or microcontroller. Again, the at least one track controller may fully or partially comprise the at least one evaluation device and/or may be part of the at least one evaluation device and/or may fully or partially be identical to the at least one evaluation device.

The tracking system comprises at least one detector according to the present invention, such as
20 at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time, such as by recording groups of data or data pairs, each group
25 of data or data pair comprising at least one position information and at least one time information.

The tracking system may further comprise the at least one detector system according to the present invention. Thus, besides the at least one detector and the at least one evaluation device
30 and the optional at least one beacon device, the tracking system may further comprise the object itself or a part of the object, such as at least one control element comprising the beacon devices or at least one beacon device, wherein the control element is directly or indirectly attachable to or integratable into the object to be tracked.

The tracking system may be adapted to initiate one or more actions of the tracking system itself and/or of one or more separate devices. For the latter purpose, the tracking system, preferably the track controller, may have one or more wireless and/or wire-bound interfaces and/or other types of control connections for initiating at least one action. Preferably, the at least one track controller may be adapted to initiate at least one action in accordance with at least one actual
40 position of the object. As an example, the action may be selected from the group consisting of: a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.

As an example of application of a tracking system, the tracking system may be used for continuously pointing at least one first object to at least one second object even though the first object and/or the second object might move. Potential examples, again, may be found in industrial applications, such as in robotics and/or for continuously working on an article even though the article is moving, such as during manufacturing in a manufacturing line or assembly line. Additionally or alternatively, the tracking system might be used for illumination purposes, such as for continuously illuminating the object by continuously pointing an illumination source to the object even though the object might be moving. Further applications might be found in communication systems, such as in order to continuously transmit information to a moving object by pointing a transmitter towards the moving object.

The optional transfer device can, as explained above, be designed to feed light propagating from the object to the detector to the optical sensor, preferably successively. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the optical sensor. The optional transfer device can also, as explained in even greater detail below, be wholly or partly a constituent part of at least one optional illumination source, for example by the illumination source being designed to provide a light beam having defined optical properties, for example having a defined or precisely known beam profile, for example at least one Gaussian beam, in particular at least one laser beam having a known beam profile.

For potential embodiments of the optional illumination source, reference may be made to WO 2012/110924 A1. Still, other embodiments are feasible. Light emerging from the object can originate in the object itself, but can also optionally have a different origin and propagate from this origin to the object and subsequently toward the transversal and/or longitudinal optical sensor. The latter case can be effected for example by at least one illumination source being used. This illumination source can for example be or comprise an ambient illumination source and/or may be or may comprise an artificial illumination source. By way of example, the detector itself can comprise at least one illumination source, for example at least one laser and/or at least one incandescent lamp and/or at least one semiconductor illumination source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. On account of their generally defined beam profiles and other properties of handleability, the use of one or a plurality of lasers as illumination source or as part thereof, is particularly preferred. The illumination source itself can be a constituent part of the detector or else be formed independently of the detector. The illumination source can be integrated in particular into the detector, for example a housing of the detector. Alternatively or additionally, at least one illumination source can also be integrated into the at least one beacon device or into one or more of the beacon devices and/or into the object or connected or spatially coupled to the object.

The light emerging from the beacon devices can accordingly, alternatively or additionally from the option that said light originates in the respective beacon device itself, emerge from the

illumination source and/or be excited by the illumination source. By way of example, the electromagnetic light emerging from the beacon device can be emitted by the beacon device itself and/or be reflected by the beacon device and/or be scattered by the beacon device before it is fed to the detector. In this case, emission and/or scattering of the electromagnetic radiation
5 can be effected without spectral influencing of the electromagnetic radiation or with such influencing. Thus, by way of example, a wavelength shift can also occur during scattering, for example according to Stokes or Raman. Furthermore, emission of light can be excited, for example, by a primary illumination source, for example by the object or a partial region of the object being excited to generate luminescence, in particular phosphorescence and/or
10 fluorescence. Other emission processes are also possible, in principle. If a reflection occurs, then the object can have for example at least one reflective region, in particular at least one reflective surface. Said reflective surface can be a part of the object itself, but can also be for example a reflector which is connected or spatially coupled to the object, for example a reflector plaque connected to the object. If at least one reflector is used, then it can in turn also be
15 regarded as part of the detector which is connected to the object, for example, independently of other constituent parts of the detector.

The beacon devices and/or the at least one optional illumination source independently from each other and generally may emit light in at least one of: the ultraviolet spectral range,
20 preferably in the range of 200 nm to 380 nm; the visible spectral range (380 nm to 780 nm); the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers. Most preferably, the at least one illumination source is adapted to emit light in the visible spectral range, preferably in the range of 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm.

The feeding of the light beam to the optical sensor can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is produced on the optional sensor area of the optical sensor. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects
30 can be detected. Preferably, the optional transfer device is designed in such a way that the light spot, for example in the case of an object arranged within a visual range of the detector, is arranged completely on a sensor region and/or on a sensor area of the optical sensor. By way of example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

The evaluation device can comprise in particular at least one data processing device, in particular an electronic data processing device, which can be designed to generate the at least one item of information on the position of the object. Thus, the evaluation device may be designed to use the number of illuminated pixels of the optical sensor or of each optical sensor
40 as input variables and to generate the at least one item of information on the position of the object by processing these input variables. The processing can be done in parallel, subsequently or even in a combined manner. The evaluation device may use an arbitrary process for generating these items of information, such as by calculation and/or using at least

one stored and/or known relationship. The relationship can be a predetermined analytical relationship or can be determined or determinable empirically, analytically or else semi-empirically. Particularly preferably, the relationship comprises at least one calibration curve, at least one set of calibration curves, at least one function or a combination of the possibilities mentioned. One or a plurality of calibration curves can be stored for example in the form of a set of values and the associated function values thereof, for example in a data storage device and/or a table. Alternatively or additionally, however, the at least one calibration curve can also be stored for example in parameterized form and/or as a functional equation.

By way of example, the evaluation device can be designed in terms of programming for the purpose of determining the items of information. The evaluation device can comprise in particular at least one computer, for example at least one microcomputer. Furthermore, the evaluation device can comprise one or a plurality of volatile or nonvolatile data memories. As an alternative or in addition to a data processing device, in particular at least one computer, the evaluation device can comprise one or a plurality of further electronic components which are designed for determining the items of information, for example an electronic table and in particular at least one look-up table and/or at least one application-specific integrated circuit (ASIC).

Overall, in the context of the present invention, the following embodiments are regarded as preferred:

Embodiment 1: A detector for determining a position of at least one object, the detector comprising:

- at least one optical sensor, the optical sensor being adapted to detect a light beam traveling from the object towards the detector, the optical sensor having at least one matrix of pixels; and
- at least one evaluation device, the evaluation device being adapted to determine a number N of pixels of the optical sensor which are illuminated by the light beam, the evaluation device further being adapted to determine at least one longitudinal coordinate of the object by using the number N of pixels which are illuminated by the light beam.

Embodiment 2: The detector according to the preceding embodiment, wherein the optical sensor is adapted to generate at least one signal indicating an intensity of illumination for each of the pixels.

Embodiment 3: The detector according to the preceding embodiment, wherein the evaluation device is adapted to compare, for each of the pixels, the signal to at least one threshold in order to determine whether the pixel is an illuminated pixel or not.

Embodiment 4: The detector according to the preceding embodiment, wherein the evaluation device is adapted to determine at least one pixel having the highest illumination out of the pixels by comparing the signals of the pixels.

Embodiment 5: The detector according to the preceding embodiment, wherein the evaluation device is further adapted to choose the threshold as a fraction of the signal of the at least one pixel having the highest illumination.

- 5 Embodiment 6: The detector according to the preceding embodiment, wherein the evaluation device is adapted to choose the threshold by multiplying the signal of the at least one pixel having the highest illumination with a factor of $1/e^2$.

- 10 Embodiment 7: The detector according to any one of the preceding embodiments, wherein the evaluation device is adapted to determine the longitudinal coordinate of the object by using a predetermined relationship between the number N of pixels which are illuminated by the light beam and the longitudinal coordinate.

- 15 Embodiment 8: The detector according to the preceding embodiment, wherein the predetermined relationship is based on the assumption of the light beam being a Gaussian light beam.

- Embodiment 9: The detector according to any one of the two preceding embodiments, wherein the predetermined relationship is

20

$$N \sim \pi \cdot w_0^2 \cdot \left(1 + \left(\frac{z}{z_0}\right)^2\right),$$

- wherein z is the longitudinal coordinate,
 wherein w_0 is a minimum beam radius of the light beam when propagating in space,
 25 wherein z_0 is a Rayleigh-length of the light beam with $z_0 = \pi \cdot w_0^2 / \lambda$, λ being the wavelength of the light beam.

- Embodiment 10: The detector according to any one of the preceding embodiments, wherein the matrix of pixels is a two-dimensional matrix.

30

- Embodiment 11: The detector according to any one of the preceding embodiments, wherein the matrix of pixels is a rectangular matrix.

- Embodiment 12: The detector according to any one of the preceding embodiments, wherein the detector comprises a plurality of the optical sensors.

35

- Embodiment 13: The detector according to the preceding embodiment, wherein the optical sensors are stacked along an optical axis of the detector.

- 40 Embodiment 14: The detector according to any one of the two preceding embodiments, wherein the detector comprises n optical sensors, wherein the evaluation device is adapted to determine

the number N_i of pixels which are illuminated by the light beam for each of the optical sensors, wherein $i \in \{1, n\}$ denotes the respective optical sensor.

Embodiment 15: The detector according to any one of the three preceding embodiments, wherein the evaluation device is adapted to compare the number N_i of pixels which are illuminated by the light beam for each optical sensor with at least one neighboring optical sensor, thereby resolving an ambiguity in the longitudinal coordinate of the object.

Embodiment 16: The detector according to any one of the four preceding embodiments, wherein the evaluation device is adapted to normalize sensor signals of the optical sensors for a power of the light beam.

Embodiment 17: The detector according to any one of the five preceding embodiments, wherein at least one of the optical sensors is transparent.

Embodiment 18: The detector according to any one of the six preceding embodiments, wherein at least two of the optical sensors have a differing spectral sensitivity, wherein the evaluation device is adapted to determine a color of the light beam by comparing sensor signals of the optical sensors having the differing spectral sensitivity.

Embodiment 19: The detector according to any one of the preceding embodiments, wherein the evaluation device is further adapted to determine at least one transversal coordinate of the object by determining a position of the light beam on the matrix of pixels.

Embodiment 20: The detector according to the preceding embodiment, wherein the evaluation device is adapted to determine a center of illumination of the matrix by the light beam, wherein the at least one transversal coordinate of the object is determined by evaluating at least one coordinate of the center of illumination.

Embodiment 21: The detector according to the preceding embodiment, wherein the coordinate of the center of illumination is a pixel coordinate of the center of illumination.

Embodiment 22: The detector according to any one of the three preceding embodiments, wherein the evaluation device is adapted to provide at least one three-dimensional position of the object.

Embodiment 23: The detector according to any one of the preceding embodiments, wherein the detector further comprises at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensor.

Embodiment 24: The detector according to the preceding embodiment, wherein the transfer device has imaging properties.

Embodiment 25: The detector according to any one of the two preceding embodiments, wherein the transfer device comprises at least one element selected from the group consisting of a lens, a mirror, a prism, a wavelength-selective element; a diaphragm.

- 5 Embodiment 26: The detector according to any one of the preceding embodiments, wherein the optical sensor comprises at least one organic photovoltaic device.

10 Embodiment 27: The detector according to any one of the preceding embodiments, wherein the optical sensor comprises at least one dye-sensitized solar cell having at least one patterned electrode.

15 Embodiment 28: The detector according to any one of the preceding embodiments, wherein the optical sensor comprises at least one first electrode, at least one second electrode and at least one light-sensitive layer embedded in between the first electrode and the second electrode.

20 Embodiment 29: The detector according to the preceding embodiment, wherein the first electrode comprises a plurality of first electrode stripes and wherein the second electrode comprises a plurality of second electrode stripes, wherein the first electrode stripes are oriented perpendicular to the second electrode stripes.

25 Embodiment 30: The detector according to any one of the preceding embodiments, wherein the optical sensor comprises at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid p-semiconducting organic material, and at least one second electrode, with the at least one n-semiconducting metal oxide, the at least one dye and the at least one p-semiconducting organic material being embedded in between the first electrode and the second electrode.

30 Embodiment 31: The detector according to the preceding embodiment, wherein both the first electrode and the second electrode are transparent.

Embodiment 32: The detector according to any one of the two preceding embodiments, wherein at least one of the first electrode and the second electrode is the patterned electrode.

35 Embodiment 33: The detector according to any one of the three preceding embodiments, wherein the first electrode comprises a plurality of first electrode stripes and wherein the second electrode comprises a plurality of second electrode stripes, wherein the first electrode stripes are oriented perpendicular to the second electrode stripes.

40 Embodiment 34: The detector according to any one of the four preceding embodiments, wherein at least one of the first electrode and the second electrode comprise an electrically conductive polymer.

Embodiment 35: The detector according to any one of the preceding embodiments, wherein the detector comprises at least one stack of the optical sensors, wherein the detector is adapted to acquire a three-dimensional image of a scene within a field of view of the detector.

- 5 Embodiment 36: The detector according to the preceding embodiment, wherein the optical sensors of the stack have differing spectral properties.

- Embodiment 37: The detector according to the preceding embodiment, wherein the stack comprises at least one first optical sensor having a first spectral sensitivity and at least one
10 second optical sensor having a second spectral sensitivity, wherein the first spectral sensitivity and the second spectral sensitivity are different.

- Embodiment 38: The detector according to any one of the two preceding embodiments, wherein the stack comprises optical sensors having differing spectral properties in an alternating
15 sequence.

- Embodiment 39: The detector according to any one of the three preceding embodiments, wherein the detector is adapted to acquire a multicolor three-dimensional image, preferably a full-color three-dimensional image, by evaluating sensor signals of the optical sensors having
20 differing spectral properties.

- Embodiment 40: The detector according to any one of the preceding embodiments, wherein the detector further comprises at least one time-of-flight detector adapted for detecting at least one distance between the at least one object and the detector by performing at least one time-of-flight measurement.
25

- Embodiment 41: The detector according to any one of the preceding embodiments, wherein the at least one optical sensor comprises at least one optical sensor having at least one sensor region and being capable of providing at least one sensor signal, wherein the sensor signal,
30 given the same total power of illumination of the sensor region by the light beam, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area.

- Embodiment 42: The detector according to any one of the preceding embodiments, wherein the
35 at least one optical sensor comprises at least one stack of optical sensors, each optical sensor having at least one sensor region and being capable of providing at least one sensor signal, wherein the sensor signal, given the same total power of illumination of the sensor region by the light beam, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area, wherein the evaluation device is adapted to compare at
40 least one sensor signal generated by at least one pixel of a first one of the optical sensors with at least one sensor signal generated by at least one pixel of a second one of the optical sensors.

Embodiment 43: A detector system for determining a position of at least one object, the detector system comprising at least one detector according to any one of the preceding embodiments, the detector system further comprising at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the
5 object, holdable by the object and integratable into the object.

Embodiment 44: The detector system according to the preceding embodiment, wherein the beacon device comprises at least one illumination source.

10 Embodiment 45: The detector system according to any one of the two preceding embodiments, wherein the beacon device comprises at least one reflective device adapted to reflect a primary light beam generated by an illumination source independent from the object.

Embodiment 46: The detector system according to any one of the three preceding
15 embodiments, wherein the detector system comprises at least two beacon devices, preferably at least three beacon devices.

Embodiment 47: The detector system according to any one of the four preceding embodiments, wherein the detector system further comprises the at least one object.
20

Embodiment 48: The detector system according to the preceding embodiment, wherein the object is a rigid object.

Embodiment 49: The detector system according to any one of the two preceding embodiments,
25 wherein the object is selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat; an article of clothing; a hat; a shoe.

Embodiment 50: A human-machine interface for exchanging at least one item of information
30 between a user and a machine, wherein the human-machine interface comprises at least one detector system according to any one of the preceding embodiments referring to a detector system, wherein the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user and held by the user, wherein the human-machine interface is designed to determine at least one position of the user by means of the detector system,
35 wherein the human-machine interface is designed to assign to the position at least one item of information.

Embodiment 51: An entertainment device for carrying out at least one entertainment function, wherein the entertainment device comprises at least one human-machine interface according to
40 the preceding embodiment, wherein the entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface, wherein the entertainment device is designed to vary the entertainment function in accordance with the information.

Embodiment 52: A tracking system for tracking a position of at least one movable object, the tracking system comprising at least one detector system according to any one of the preceding embodiments referring to a detector system, the tracking system further comprising at least one track controller, wherein the track controller is adapted to track a series of positions of the object at specific points in time.

Embodiment 53: A camera for imaging at least one object, the camera comprising at least one detector according to any one of the preceding embodiments referring to a detector.

Embodiment 54: A method for determining a position of at least one object, the method comprising the following steps:

- at least one detection step, wherein at least one light beam traveling from the object to a detector is detected by at least one optical sensor of the detector, the at least one optical sensor having at least one matrix of pixels; and
- at least one evaluation step, wherein a number N of pixels of the optical sensor is determined which are illuminated by the light beam, wherein at least one longitudinal coordinate of the object is determined by using the number N of pixels which are illuminated by the light beam.

Embodiment 55: The method according to the preceding embodiment, wherein the optical sensor generates at least one signal indicating an intensity of illumination for each of the pixels.

Embodiment 56: The method according to the preceding embodiment, wherein, in the evaluation step, for each of the pixels, the signal is compared to at least one threshold in order to determine whether the pixel is an illuminated pixel or not.

Embodiment 57: The method according to the preceding embodiment, wherein, in the evaluation step, at least one pixel having the highest illumination out of the pixels is determined by comparing the signals of the pixels.

Embodiment 58: The method according to the preceding embodiment, wherein the threshold is chosen as a fraction of the signal of the at least one pixel having the highest illumination.

Embodiment 59: The method according to the preceding embodiment, wherein the threshold is chosen by multiplying the signal of the at least one pixel having the highest illumination with a factor of $1/e^2$.

Embodiment 60: The method according to any one of the preceding method embodiments, wherein the longitudinal coordinate of the object is determined by using a predetermined relationship between the number N of pixels which are illuminated by the light beam and the longitudinal coordinate.

Embodiment 61: The method according to the preceding embodiment, wherein the predetermined relationship is based on the assumption of the light beam being a Gaussian light beam.

- 5 Embodiment 62: The method according to any one of the two preceding embodiments, wherein the predetermined relationship is

$$N \sim \pi \cdot w_0^2 \cdot \left(1 + \left(\frac{z}{z_0}\right)^2\right),$$

- 10 wherein z is the longitudinal coordinate,
wherein w_0 is a minimum beam radius of the light beam when propagating in space,
wherein z_0 is a Rayleigh-length of the light beam with $z_0 = \pi \cdot w_0^2 / \lambda$, λ being the wavelength of the light beam.

- 15 Embodiment 63: The method according to any one of the preceding method embodiments, wherein the matrix of pixels is a two-dimensional matrix.

Embodiment 64: The method according to any one of the preceding method embodiments, wherein the matrix of pixels is a rectangular matrix.

- 20 Embodiment 65: The method according to any one of the preceding method embodiments, wherein the detector comprises a plurality of the optical sensors.

- 25 Embodiment 66: The method according to the preceding embodiment, wherein the optical sensors are stacked along an optical axis of the detector.

- Embodiment 67: The method according to any one of the two preceding embodiments, wherein the detector comprises n optical sensors, wherein the number N_i of pixels which are illuminated by the light beam is determined for each of the optical sensors, wherein $i \in \{1, n\}$ denotes the
30 respective optical sensor.

- Embodiment 68: The method according to any one of the three preceding embodiments, wherein the number N_i of pixels which are illuminated by the light beam for each optical sensor is compared with at least one neighboring optical sensor, thereby resolving an ambiguity in the
35 longitudinal coordinate of the object.

Embodiment 69: The method according to any one of the four preceding embodiments, wherein the sensor signals of the optical sensors are normalized for a power of the light beam.

- 40 Embodiment 70: A use of the detector according to any one of the preceding embodiments relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a safety

application; a human-machine interface application; a tracking application; a photography application; a use in combination with at least one time-of-flight detector.

Brief description of the figures

5

Further optional details and features of the invention are evident from the description of preferred exemplary embodiments which follows in conjunction with the dependent claims. In this context, the particular features may be implemented alone or with several in combination. The invention is not restricted to the exemplary embodiments. The exemplary embodiments are shown schematically in the figures. Identical reference numerals in the individual figures refer to identical elements or elements with identical function, or elements which correspond to one another with regard to their functions.

Exemplary embodiments

Fig. 1 shows, in a highly schematic illustration, an exemplary embodiment of a detector 110, having a plurality of optical sensors 112. The detector 110 specifically may be embodied as a camera 111 or may be part of a camera 111. The camera 111 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible. Fig. 1 further shows an embodiment of a detector system 114, which, besides the at least one detector 110, comprises one or more beacon devices 116, which, in this exemplary embodiment, are attached and/or integrated into an object 118, the position of which shall be detected by using the detector 110. Fig. 1 further shows an exemplary embodiment of a human-machine interface 120, which comprises the at least one detector system 114, and, further, an entertainment device 122, which comprises the human-machine interface 120. The figure further shows an embodiment of a tracking system 124 for tracking a position of the object 118, which comprises the detector system 114. The components of the devices and systems shall be explained in further detail in the following.

The detector 110, besides the one or more optical sensors 112, comprises at least one evaluation device 126. The evaluation device 126 may be connected to the optical sensors 112 by one or more connectors 128 and/or one or more interfaces. Further, the connector 128 may comprise one or more drivers and/or one or more measurement devices for generating sensor signals, as will be explained with regard to Figs. 2A and 2B below. Further, instead of using the at least one optional connector 128, the evaluation device 126 may fully or partially be integrated into the optical sensors 112 and/or into a housing 130 of the detector 110. Additionally or alternatively, the evaluation device 126 may fully or partially be designed as a separate device.

In this exemplary embodiment, the object 118, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element 132, the position of which may be manipulated by a user 134. As an example, the object 118 may be or may comprise a bat, a record, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 118 are possible. Further, the user 134 himself or herself may be considered as the object 118, the position of which shall be detected.

As outlined above, the detector 110 comprises the plurality of optical sensors 112. The optical sensors 112 may be located inside the housing 130 of the detector 110. Further, at least one transfer device 136 may be comprised, such as one or more optical systems, preferably comprising one or more lenses 138. An opening 140 inside the housing 130, which, preferably, is located concentrically with regard to an optical axis 142 of the detector 110, preferably defines a direction of view 144 of the detector 110. A coordinate system 146 may be defined, in which a direction parallel or antiparallel to the optical axis 142 is defined as a longitudinal direction, whereas directions perpendicular to the optical axis 142 may be defined as transversal directions. In the coordinate system 146, symbolically depicted in Fig. 1, a

longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other types of coordinate systems 146 are feasible.

The detector 110 may comprise one or more of the optical sensors 112. Preferably, as depicted in Fig. 1, a plurality of optical sensors 112 is comprised, which, more preferably, are stacked along the optical axis 142, in order to form a sensor stack 148. In the embodiment shown in Fig. 1, five optical sensors 112 are depicted. It shall be noted, however, that embodiments having a different number of optical sensors 112 are feasible.

The optical sensors 112 or, at least, the optical sensors 112 besides the optical sensor 112 facing away from the object 118, preferably are transparent to light beams 150 traveling from the object 118 and/or one or more of the beacon devices 116 towards the detector 110, such that the at least one light beam 150 sequentially passes the optical sensors 112.

The detector 110 is adapted for determining a position of the at least one object 118. For this purpose, as will be explained with respect to Fig. 2A and the exemplary embodiment of one of the optical sensors 112 depicted therein, each of the optical sensors 112 comprises a matrix 152 of pixels 154. In this exemplary embodiment, the matrix 152 is a rectangular matrix, in which the pixels 154 are arranged in rows in an x-dimension and columns in a y-dimension, as symbolically depicted by the coordinate system 146 depicted in Fig. 2A. The plane of the matrix 152 may be perpendicular to the optical axis 142 of the detector 110 and, thus, may be perpendicular to the longitudinal coordinate z. However, other embodiments are feasible, such as embodiments having non-planar optical sensors 112 and/or embodiments having non-rectangular matrices of pixels 154.

The detector 110 is adapted to determine a position of the object 118, and the optical sensor 112 is adapted to detect the light beam 150 traveling from the object 118 towards the detector 110, specifically from one or more of the beacon devices 116. The light beam 150, directly and/or after being modified by the transfer device 136, such as being focused by the lens 138, creates a light spot 156 on a sensor surface 158 of the optical sensor 112 or of each of the optical sensors 112. Each of the pixels 154 may be adapted to generate an individual signal, also referred to as a sensor signal or a pixel signal, which represents an intensity of illumination of the respective pixel. Thus, as an example, in Fig. 2A, a multiplexing measuring scheme is depicted which may be used for generating sensor signals for each of the pixels 154. Thus, each of the columns of the matrix 152 may be connected to a respective current measurement device 160. A switch 162 may be provided for contacting each of the rows of the matrix 152. Thus, a multiplexing measurement scheme may be implemented in which the rows of the matrix 152 are contacted sequentially. Thus, in a first step, the uppermost row of the matrix 152 may be contacted by switch 162, thereby allowing for measuring electrical currents through each of the pixels of the uppermost row of the matrix 152. The currents may be provided in an analogue format and/or may be transformed into a digital format, such as by providing one or more analogue-digital-converters. Thus, measurement values for each of the pixels of the uppermost pixel row of matrix 152 may be generated, such as by providing 4-bit grayscale values, 8-bit

grayscale values or other information formats. The respective information values representing the sensor signals of the pixels 154 may be provided to the evaluation device 126, which may comprise one or more volatile and/or non-volatile data memories 164. Subsequently, by switching switch 162 to contact the second row of the matrix 152, sensor signals for each bit of the second row are generated, followed by sensor values of the subsequent rows. After finishing one measurement of the complete matrix 152, the routine may start anew, such as by contacting the first row of the matrix 152 again. Thus, by using this multiplexing scheme or other multiplexing schemes, sensor signals for each of the pixels 154 may be generated. Since the multiplexing may be performed at a high repetition rate, it may be assumed that neither the intensity of the light beam 150 nor the position of the light spot 156 changes significantly during one multiplexing cycle. However, it shall be noted that, specifically for fast moving objects 118, other schemes for generating sensor values may be used, such as measurement schemes creating sensor values for each pixel 154 of the matrix 152 simultaneously.

As outlined above, preferably, the matrix 152 preferably contains at least 10 pixel rows and at least 10 pixel columns. Thus, as an example, at least 20 pixel rows and at least 20 pixel columns may be present, preferably at least 50 pixel rows and 50 pixel columns and, more preferably, at least 100 pixel rows and 100 pixel columns. Thus, specifically, standard formats may be used, such as VGA and/or SVGA.

The sensor signals provided by the pixels 154 may be used to determine the position of the object 118. Thus, firstly, as outlined in Fig. 2A, the sensor signals of the pixels 154 may be compared, in order to determine the one or more pixels having the highest intensity of illumination by the light beam 150. This center of illumination, such as the center of the light spot 156, may be used for determining coordinates $x_{\max}$ and $y_{\max}$, representing transversal coordinates of the light spot 156. By using known imaging equations, such as the well-known lens equation, a transversal coordinate of the object 118 and/or the respective beacon device 116 emitting the light beam 150 in the coordinate system 146 may be determined from the coordinates $x_{\max}$, $y_{\max}$. Thus, by determining a transversal position of the light spot 156 on the sensor surface 158 of the optical sensor 112, a transversal position of the object 118 and/or a part of the object 118 may be determined.

Further, as outlined above and as will be explained in further detail below, the detector 110 is adapted to determine a longitudinal coordinate of the object 118 and/or of the at least one beacon device 116. For this purpose, a diameter and/or equivalent diameter of the light spot 156 may be evaluated, as will be explained in the following.

Thus, the evaluation device 126 is adapted to determine a number N of pixels 152 which are illuminated by the light beam 150. For this purpose, a threshold method may be used, in which the sensor signals of each of the pixels 154 are compared to one or more thresholds determining whether the respective pixel 154 is illuminated or not. The one or more thresholds may determine a borderline 166 of the light spot 156, as depicted in Fig. 2A. As an example, assuming a Gaussian illumination with a typical Gaussian intensity profile, the borderline 166

may be chosen as a line at which the intensity of the light spot 156 has dropped from a central intensity I_0 (which is the intensity at pixel coordinates $x_{\max}$, $y_{\max}$) to $1/e^2 \cdot I_0$.

The threshold method may easily be implemented, as an example, by using a histogram analysis of the sensor values of one image (such as of one scan of a multiplexing scheme and/or of one image of pixels simultaneously taken), as symbolically depicted in Fig. 2B. It shall be noted that the histogram analysis in Fig. 2B does not fully correspond to the image as depicted in Fig. 2A. In Fig. 2B, on a horizontal axis, the sensor signals of the pixels 154 acquired in one image, denoted by " I " (non withstanding the fact that other sensor signals than currents may be used, such as bit values or grayscale values), are given. On the vertical axis, denoted by "#", the counts for each of the sensor signals are given, i.e. the number of pixels 154 providing the respective sensor signal I . Thus, as an example, grayscale values may be given on the horizontal axis, and the number of pixels showing the respective grayscale values in one image may be given on the vertical axis. The highest sensor signal noted within this image is marked as I_0 . By providing an appropriate threshold $1/e^2 \cdot I_0$ (and/or the closest integer value to this threshold, such as the next integer value above $1/e^2 \cdot I_0$ and/or the next integer value below $1/e^2 \cdot I_0$ – within the present invention, these options shall be enclosed), as symbolically depicted in Fig. 2B, the pixel counts in this histogram analysis may be divided into counts for non-illuminated pixels 154 (denoted by reference number 168 in Fig. 2B and marked by white bars), i.e. the sensor signals of pixels 154 outside the borderline 166 in Fig. 2A, and counts for illuminated pixels (denoted by reference number 170 in Fig. 2B and marked by filled bars), i.e. pixels 154 within the borderline 166 in Fig. 2A. Thus, by using this threshold method and/or other threshold methods, illuminated pixels and non-illuminated pixels may be distinguished, such as by using an appropriate histogram analysis.

This distinguishing of illuminated and non-illuminated pixels allows for counting the number N of the pixels 154 which are illuminated by the light beam 150. Thus, an integration over the illuminated pixels 170 in Fig. 2B and their respective counts leads to the number N of illuminated pixels. Other methods for determining the number N of illuminated pixels may be used additionally or alternatively.

As given in equation (4) or, for a plurality of optical sensors 112, in equation (4') above, the number N of illuminated pixels is proportional to the area of the light spot 156. Thus, since the diameter of any type of light beam 150 varies with propagation, by evaluating the number N of illuminated pixels, a longitudinal coordinate of the object 118 or, specifically, of one or more beacon devices 116 emitting the respective light beam 150 may be determined. As an example, by assuming Gaussian properties of the light beam 150, equations (6) and/or (6') given above may be used. As an example, the light beam 150 itself may have Gaussian properties.

Additionally or alternatively, the at least one transfer device 136 with the at least one optional lens 138 may be used for beam-shaping wherein, still, the spatial information on the longitudinal position of the object 118 or, specifically, the respective beacon device 116, is contained in the propagation properties of the shaped light beam 150.

In case the detector 110 has a narrow viewing angle, the distance between the object 118 and the detector 110 may be considered a distance in the z-dimension, only. However, since, by using the matrix 152 and e.g. the algorithm given above, transversal coordinates x and/or y may be determined in addition, the full traveling distance of the light beam 150 may easily be
5 calculated, taking into account an offset of the respective beacon device 116 from the optical axis 152. Specifically, for objects which are located off-axis, reference may be made to the explanations regarding figure 5 below.

As outlined above, preferably, a plurality of the optical sensors 112 is provided, such as by
10 providing the sensor stack 148. The redundancy of the optical sensors 112 may be used in various ways.

Thus, as outlined above, by determining the number N of illuminated pixels for one of the optical sensors 112, a beam waste may be determined. However, as may easily be derived from one
15 or more of equations (3), (6) or (6') given above, the longitudinal coordinate z derived thereby is ambiguous with respect to the focal point. Thus, by simply determining one beam waste and/or one number N of illuminated pixels, uncertainty may arise whether the respective image was taken at a specific distance z before or after a focal point of the Gaussian light beam 150. This ambiguousness may be resolved in various ways. Thus, firstly, a movement of the detector 110
20 and/or the object 118 may be tracked, such as by using a series of images and/or a track controller 172 of the tracking system 124. Thus, a history of movements of the object 118 may be tracked, providing additional spatial information of the object 118 may allow for determining whether the respective optical sensor 112 is positioned before or after a focal point of the light beam 150. Additionally or alternatively, however, as will be explained with respect to Figs. 3A
25 and 3B, a redundancy of information provided by the optical sensor stack 148 may be used for resolving this ambiguousness of the longitudinal coordinate. Thus, in Fig. 3A, a side view of a simplified beam path of the light beam 150, traveling from one or more of the beacon devices 116 towards the detector 110, is depicted. As can be seen, due to Gaussian beam propagation properties, the light beam 150 within the sensor stack 148 narrows, up to a focal point 174,
30 which, in this exemplary embodiment, occurs close to the middle one of the optical sensors 112. Other embodiments of the beam path are feasible. In Fig. 3B, views of the sensor surfaces 158 of the optical sensors and the respective light spots 156 for each of the optical sensors 112 of the setup in Fig. 3A are given. The optical sensors 112 are numbered by numbers 1 through 5, as in Fig. 3A. As can be seen, the light spot 156 in the middle optical sensor 112, close to the
35 focal point 174, is smallest, whereas the diameter of the light spots 156 to the right and to the left of this middle sensor (sensor number 3) widens. As can be seen by comparing the diameter of the light spots 156 of the optical sensors 1 and 5 or 2 and 4, the diameter is ambiguous. However, by comparing a specific diameter with diameters of light spots of neighboring optical sensors, it may be determined whether the light beam widens or narrows, i.e. whether the
40 respective optical sensor 112 is positioned before or after the focal point 174. Thus, the above-mentioned ambiguousness may be resolved, and a z-coordinate may be determined, such as in the coordinate system 146 and/or in another coordinate system.

The optical sensors 112 of the sensor stack 148, as outlined above, preferably are transparent to the light beam 150. For the last optical sensor 112 of the sensor stack 148, facing away from the object 118, such as the optical sensor 112 named "5" in Fig. 3A, a transparency not necessarily has to be present. Thus, this last optical sensor 112 may also be intransparent.

As further outlined above, providing a plurality of the optical sensors 112, such as in a stacked fashion, may, additionally or alternatively, also be used for other purposes. Thus, the optical sensors 112 may provide different spectral sensitivities, in order to provide at least one information on a color of the light beam 150. Thus, in Fig. 3C, extinction coefficients of three of the optical sensors 112 are given as a function of the wavelength λ . These extinction coefficients or any other measure indicating a spectrum of absorption of the respective optical sensors 112, may be adjusted by providing appropriate absorptive materials, such as appropriate dyes, within the optical sensors 112. As an example, in case the optical sensors 112 comprise dye-sensitized solar cells (DSCs, specifically sDSCs), an appropriate dye may be chosen. As an example, in Fig. 3C, different spectral sensitivities (such as normalized sensitivities) ε are given for optical sensors 1, 2 and 3, as an example, as a function of the wavelength λ . Assuming that the total power of the light beam remains identical for all light spots 156 on the sensor surfaces 158, or, with known attenuation of the light beam 150 after passing a specific optical sensor 112, a ratio of the sensor signals of the respective optical sensors 112 having different absorption properties may be used for determining a color of the light beam 150. As an example, for each of the optical sensors 112, a total sensor signal may be determined by adding the sensor signals of each of the pixels 154. Alternatively, a respective representative sensor signal for each of the optical sensors 112 may be determined, such as a peak value or maximum value of the sensor signals. Again, alternatively, the sensor signals of the pixels 154 within the light spots 156 may be integrated, thereby generating a representative sensor signal for each of the optical sensors 112. In the exemplary embodiment depicted in Fig. 3C, an information on a green component of the light beam 150, e.g., may be determined by dividing the sensor signal of the third optical sensor 112 (sensor number 3) by a sum of the sensor signals of optical sensors 1, 2 and 3. Similarly, a yellow component of the light beam 150 may be determined by dividing the sensor signal of the first optical sensor by a sum of the sensor signals of optical sensors 1, 2 and 3. Again, similarly, a red component of the light beam 150 may be determined by dividing the sensor signal of the second optical sensor 112 by a sum of the sensor signals of optical sensors 1, 2 and 3. Other embodiments and/or algorithms for determining colors are feasible. Thus, as an example, the absorption spectra of three of the optical sensors 112 may be similar to the absorption materials used as a basis of the above-mentioned CIE coordinate system, thereby directly allowing for determining CIE coordinates of the light beam 150. It shall be noted that the determination of the color of the light beam 150 is independent from the above-described determination of the longitudinal coordinate of the object 118, since the above-mentioned algorithm is simply based on a counting of illuminated and non-illuminated pixels, independent from the color of the light beam 150. Thus, e.g. in the threshold method and histogram analysis described with regard to Figs. 2A and 2B above, an internal normalization of the intensity of the light beam and/or the color of the light beam may take place, since, as outlined above, the threshold may be chosen as a function and/or fraction of a

maximum intensity and/or of a maximum sensor signal. Thus, the determination of the longitudinal coordinate by using the above-mentioned pixel count is independent from the fact that the respective optical sensors 112 within the sensor stack 148 may have different spectral absorption properties.

As outlined above, the determination of a position of the object 118 and/or a part thereof by using the detector 110 may be used for providing a human-machine interface 120, in order to provide at least one item of information to a machine 176. In the embodiment schematically depicted in Fig. 1, the machine 176 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 126 even may fully or partially be integrated into the machine 176, such as into the computer. The same holds true for the track controller 172, which may also fully or partially form part of the computer of the machine 176.

Similarly, as outlined above, the human-machine interface 120 may form part of an entertainment device 122. The machine 176, specifically the computer, may also form part of the entertainment device 122. Thus, by means of the user 134 functioning as the object 118 and/or by means of the user 134 handling a control device 132 functioning as the object 118, the user 134 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment function, such as controlling the course of a computer game.

As outlined above, the one optical sensor 112 and/or one or more of the optical sensors 112 preferably may fully or partially be transparent with regard to the light beam 150. In Figs. 4A to 4C, an exemplary setup of a transparent optical sensor 112 is depicted in various views.

Therein, Fig. 4A shows a top view, Fig. 4B shows a cross-sectional view along line A-A in Fig. 4A, and Fig. 4C shows a cross-sectional view along line B-B in Fig. 4A.

The optical sensor 112 may comprise a transparent substrate 178, such as a glass substrate and/or a plastic substrate. For potential details of the substrate 178, reference may be made to documents WO 2012/110924 A1 and US provisional applications no. 61/739,173 and/or 61/749,964. However, other embodiments are feasible. The illumination by the light beam 150 may take place through the substrate 178 and/or from an opposite side. Thus, the bottom side of the substrate 178 in Fig. 4B may form the sensor surface 158. Alternatively, an illumination from the opposing surface may take place.

On top of the substrate 178, a first electrode 180 is deposited, which, in this embodiment, may comprise a plurality of first electrode stripes 182. Preferably, the first electrode 180 is fully or partially transparent. Thus, as an example, the first electrode 180 may fully or partially be made of a transparent conductive oxide, such as fluorine-doped tin oxide (FTO) and/or indium-doped tin oxide (ITO). For further details of the first electrode 180, reference may be made to WO 2012/110924 A1 and/or one or more of US provisional applications no. 61/739,173 and/or 61/749,964. However, other embodiments are feasible. A patterning of the first electrode stripes 182 may take place by appropriate patterning techniques which are generally known to the

skilled person in the field of display technology, e.g. etching and/or lithographic techniques. Thus, as an example, a large-area coating by the material of the first electrode 180 on the substrate 178 may be provided, wherein the areas of the first electrode stripes 182 may be covered by photoresist and wherein the uncovered regions may be etched by an appropriate
5 etching means, as known to the skilled person in the technical field of display manufacturing, such as LCD manufacturing.

On top of the first electrode 180, one or more light-sensitive layers 184, such as a light-sensitive layer setup comprising one, two, three or more layers, are deposited. As an example, the light-
10 sensitive layers 184 may comprise a layer setup of a dye-sensitized solar cell (DSC), more specifically of a solid dye-sensitized solar cell (sDSC), such as disclosed in WO 2012/110924 A1 and/or one or more of the US provisional applications 61/739,173 and/or 61/749,964. Thus, the light-sensitive layers 184 may comprise one or more layers of an n-semiconducting metal oxide, preferably a nanoporous metal oxide, such as TiO_2 , which may directly or indirectly be
15 deposited on top of the first electrode 180. Further, the n-semiconducting metal oxide may fully or partially be sensitized with one or more dyes, such as one or more organic dyes, preferably one or more of the dyes disclosed in WO 2012/110924 A1 and/or one or more of US provisional applications no. 61/739,173 and/or 61/749,964. Other embodiments are feasible.

On top of the dye-sensitized n-semiconducting metal oxide, one or more layers of a p-semiconducting and/or conducting material may be deposited. Thus, preferably, one or more solid p-semiconducting organic materials may be used which may directly or indirectly be deposited on top of the n-semiconducting metal oxide. As an example, reference may be made to one or more of the p-semiconducting materials as disclosed in WO 2012/110924 A1 and/or
20 as disclosed in one or more of US provisional applications no. 61/739,173 and/or 61/749,964. As a preferred example, Spiro-MeOTAD may be used.

It shall be noted that the named light-sensitive layers 184, which preferably may comprise one or more organic light-sensitive layers 184, may also be provided in a different layer setup. Thus,
30 basically, any type of light-sensitive material, such as an organic, inorganic or hybrid layer setup, may be used, which is adapted to provide an electric signal in accordance with an illumination of the layer setup.

As can be seen specifically in the top view of Fig. 4A, the one or more light-sensitive layers 184 preferably are patterned such that one or more contact areas 186 for contacting the first electrode stripes 182 remain uncovered by the light-sensitive layer 184. This patterning may be performed in various ways. Thus, a large-area coating of the light-sensitive layers 184 may be applied, and the contact areas 186 may, subsequently, be uncovered, such as by laser ablation and/or mechanical ablation. Additionally or alternatively, however, the one or more light-
40 sensitive layers 184 may fully or partially be applied to the setup in a patterned way, such as by using appropriate printing techniques. Combinations of the named techniques are feasible.

On top of the at least one light-sensitive layer 184, at least one second electrode 188 is deposited. Again, this at least one second electrode 188 preferably may comprise a plurality of electrode stripes, which, in this embodiment, are denoted by reference number 190 (second electrode stripes). As can be seen specifically in the top view of Fig. 4A, the second electrode stripes 190 preferably are oriented essentially perpendicular to the first electrode stripes 182, such as at an angle of $90^\circ \pm 20^\circ$, preferably $90^\circ \pm 10^\circ$ and more preferably $90^\circ \pm 5^\circ$. It shall be noted, however, that other electrode geometries for the first electrode 180 and the second electrode 188 are feasible.

As can be seen in the top view of Fig. 4A, each of the second electrode stripes 190 comprises at least one contact area 192 which allows for an electrical contacting of the second electrode stripes 190.

As further may be derived from the top view in Fig. 4A, the layer setup of the optical sensor 112 provides a plurality of areas in which the second electrode stripes 190 cross the first electrode stripes 182. Each of these areas, by itself, forms an individual optical sensor, which is also referred to as a pixel 154 and which may be contacted electrically by electrically contacting the appropriate contact areas 186, 192 of the respective electrode stripes 182, 190. Thus, by measuring an electrical current through these individual optical sensors, each of the pixels 154 may provide an individual optical signal, as explained above. In this embodiment, the pixels 154 may be arranged in a rectangular setup, forming a rectangular matrix 152. It shall be noted, however, that other setups are feasible, such as non-rectangular matrix setups. Thus, as an example, honeycomb structures or other geometric setups may be realized.

In addition to the layer setup shown in Figs. 4A to 4C, the optical sensor 112 may comprise one or more encapsulation elements, such as one or more encapsulation layers and/or one or more cover elements, such as glass lids and/or plastic lids. The latter, for example, may be glued on top of the layer setup shown e.g. in Figs. 4B and 4C, preferably by leaving open the contact areas 186, 192.

The second electrode stripes 190 preferably may comprise one or more metal layers, such as one or more layers of a metal selected from the group consisting of: Al, Ag, Au, Pt, Cu. Additionally or alternatively, combinations of two or more metals may be used, such as metal alloys. As an example, one or more metal alloys selected from the group of NiCr, AlNiCr, MoNb and AlNd may be used. Still, other embodiments are feasible. Preferably, as for the first electrode stripes 182, the second electrode stripes 190 may fully or partially be transparent. This transparency may be realized in various ways. Thus, as an example, thin metal layers may be used, such as metal layers having a thickness of below 50 nm, such as a thickness of ≤ 30 nm or ≤ 20 nm. At these layer thicknesses, the typical metals still are transparent. Additionally or alternatively, however, non-metallic conductive materials may be used, such as conductive polymers. As an example, PEDOT:PSS and/or PANI may be used. For further potential details of the setup of the second electrode 188, reference may be made to WO 2012/110924 A1, US 61/739,173 and/or 61/749,964, as mentioned above.

The second electrode stripes 190 may be applied to the layer setup by using typical application techniques. Thus, as an example, one or more metal layers may be deposited by using physical vapor deposition (such as evaporation and/or sputtering). Conductive non-metallic materials, such as conductive polymers, may e.g. be applied by using typical coating techniques, such as spin-coating and/or printing. Other techniques are feasible. The patterning of the second electrode stripes 190 may be performed in various ways. Thus, when using evaporation techniques and/or vacuum deposition techniques, a mask technique may be used, such as evaporation through shadow masks. Additionally or alternatively, printing may be performed in a patterned way. Thus, as an example, screen-printing and/or inkjet-printing may be used for patterning conductive polymers. Again, additionally or alternatively, one or more separating patterns may be provided on the layer setup and/or on the substrate 178, such as photoresist patterns, which sub-divide the second electrode 188 into the second electrode stripes 190.

It shall further be noted that the layer setup of the first electrode 180, the one or more light-sensitive layers 184 and the second electrode 188 may as well be inverted. Thus, as an example, the layer setup of the DSC, specifically the sDSC, may be inverted, as compared to the layer setup described above. Further, additionally or alternatively, the setup of the electrodes 180, 188 may be inverted, thus providing the second electrode 188 on the substrate 178, providing the one or more light-sensitive layers 184 directly or indirectly on top of this second electrode, and providing the first electrode 180 on top of this at least one light-sensitive layer 184. Various variations of the setup are feasible. Further, it shall be noted that one or more of electrodes 180, 188 may as well be intransparent. Thus, as explained above, a detector 110 having only one optical sensor 112 is feasible. In this case, the optical sensor 112 not necessarily has to be transparent. Thus, as an example, the second electrode 188 may be intransparent, such as by using thick metal layers, in case light is transmitted into the optical sensor 112 via sensor surface 158. In case light is transmitted into the optical sensor 112 from the other side, the first electrode 180 may be an intransparent electrode. Further, in case a sensor stack 148 is used, as e.g. in the setup of Fig. 1, the last optical sensor 112 of the sensor stack 148, facing away from the object 118, not necessarily has to be transparent. Thus, an intransparent optical sensor 112 may be used.

In figure 5, in addition to the explanations given above with regard to figures 2A to 3B, a further embodiment of a detector 110 and of a camera 111 are shown in a partial perspective view, which, in the following, will be used for further explaining an embodiment for determining the position of at least one object 118 (not shown in this figure) emitting a light beam 150. The detector 110 and/or the camera 111 may be part of a detector system 114, a human-machine interface 120, an entertainment device 122 or a tracking system 124 and may comprise additional components which are not depicted in figure 5. Thus, as an example, the evaluation device 126 is not depicted. With regard to potential embodiments of the evaluation device 126 and/or with regard to further details, reference may be made to the embodiments shown above.

As can be seen, in this preferred embodiment, the detector 110, again, comprises a plurality of optical sensors 112, which, again, are arranged in a sensor stack 148. For potential

embodiments of the optical sensors 112 and the sensor stack 148, reference may be made to the embodiments disclosed above.

The sensor stack 148 comprises at least two optical sensors 112, wherein, in this embodiment, only two optical sensors 112 are shown, one optical sensor 112 facing towards the object 118, of the last optical sensor 112 in figure 5) and one optical sensor 112 facing away from the object 118 (right optical sensor 112). Preferably, at least one of the optical sensors 112 is at least partially transparent with regard to the light beam 150, such that at least part of the light beam 150, in an unattenuated fashion or in an attenuated fashion, with unchanged spectral properties or modified spectral properties, may pass through the optical sensor 112. Thus, in figure 5, the left optical sensor 112 may fully or partially be transparent, whereas the right optical sensor 112 may be intransparent or transparent.

The light beam 150 may propagate in a direction of propagation 194, along an axis of propagation 196, which may be parallel or nonparallel to the z-axis which, preferably, is oriented orthogonally to the sensor surfaces 158 of the optical sensors 112.

As outlined above with regard to figures 2A and 2B, and as outlined above with regard to figures 3A and 3B, light spots 156 created by the light beam 150 on the optical sensors 112 may be evaluated. Thus, as outlined above, for one or more of the light spots 156, a center 198 may be determined, at least within the boundaries of resolution given by the pixels 154. As an example, in figure 5, the optical sensors 112 contain matrices 152 of pixels 154, wherein each pixel is characterized by its row (symbolically denoted by row identifier A to I in figure 5) and its column (symbolically denoted by column identifier 1 to 7 in figure 5). Other embodiments of identifying pixel coordinates are feasible, such as by using numbers both as row identifiers and as column identifiers. Thus, in the exemplary embodiment shown in figure 5, the center 198 of the light spot 156 for the left optical sensor 112 may be identified to be located in between rows D and E and in between columns 4 and 5, whereas the center 198 of the light spot 156 on the right optical sensor 112 may be identified to be located in row D and column 6. Thus, by connecting the centers 198, the axis of propagation 196 of the light beam 150 may easily be determined. Consequently, the direction of the object 118 with regard to the detector 110 may be determined. Thus, since the center 198 of the light spot 156 on the right optical sensor 112 is shifted towards the right (i.e. towards higher column numbers), it may be determined that the object 118 is located off centered from the z-Axis towards the right.

Further, as outlined above, by evaluating beam waist w_0 , a longitudinal coordinate of the object 118 may be determined. Thus, as an example, the beam waist may be dependent on the longitudinal coordinate according to one or more of the above-mentioned relationships, specifically according to a Gaussian relationship. In case the direction of propagation 194 is non-parallel to the optical axis or z-coordinate, as depicted in figure 5, the longitudinal coordinate of the object 118 may be a coordinate along the axis of propagation 196. Since, e.g. by comparing the coordinates of the centers 198, the axis of propagation 196 may easily be determined, and angular relationship between the z-axis and the axis of propagation 196 is known, and, thus, a coordinate transformation is easily possible. Thus, generally, by evaluating

the pixel counts of one or more optical sensors 112, the position of the object 118 may be determined. Further, since each of the optical sensors 112 may be used for generating an image of the object 118 and since the longitudinal coordinate of the object 118 and/or of one or more points of the object 118 are known, a three-dimensional image of the object 118 may be generated.

In Figure 6, a schematic setup of a detector 110 according to the present invention to be used as a light-field camera is shown. Basically, the setup shown in Figure 6 may correspond to the embodiment shown in Figures 1 or any other of the embodiments shown herein. The detector 110 comprises a sensor stack 148 of optical sensors 112, also referred to as pixelated sensors, which specifically may be transparent. As an example, pixelated organic optical sensors may be used, such as organic solar cells, specifically sDSCs. In addition, the detector 110 may comprise at least one transfer device 136 such as at least one lens 138 or lens system, adapted for imaging objects 118. Additionally, in this embodiment or other embodiments, the detector 110 may comprise at least one imaging device 196, such as a CCD and/or a CMOS imaging device.

As outlined above, the detector 110 in the embodiment shown herein is suited to act as a light-field camera. Thus, light-beams 150 propagating from various objects 118 or beacon devices 116, symbolically denoted by A, B and C in Figure 6, are focused by the transfer device 136 into corresponding images, denoted by A', B' and C' in Figure 6. By using the stack 148 of optical sensors 112, a three-dimensional image may be captured. Thus, specifically in case the optical sensors 112 are FiP-sensors, i.e. sensors for which the sensor signals are dependent on the photon density, the focal points for each of the light beams 150 may be determined by evaluating sensor signals of neighboring optical sensors 112. Thus, by evaluating the sensor signals of the stack 148, beam parameters of the various light beams 150 may be determined, such as a focal position, spreading parameters or other parameters. Thus, as an example, each light beam 150 and/or one or more light beams 150 of interest may be determined in terms of their beam parameters and may be represented by a parameter representation and/or vector representation. Thus, since the optical qualities and properties of the transfer device 136 are generally known, as soon as the beam parameters of the light beams 150 are determined by using the stack 148, a scene captured by the optical detector 110, containing one or more objects 118, may be represented by a simplified set of beam parameters. For further details of the light-field camera shown in Figure 6, reference may be made to the description of the various possibilities given above.

Further, as outlined above, the optical sensors 112 of the stack 148 of optical sensors may have identical or different wavelength sensitivities. Thus, the stack 148 may, besides the optional imaging device 196, comprise two types of optical sensors 112, such as in an alternating fashion. Therein, a first type and a second type of optical sensors 112 may be provided in the stack 148. The optical sensors 112 of the first type and the second type specifically may be arranged in an alternating fashion along the optical axis 142. The optical sensors 112 of the first type may have a first spectral sensitivity, such as a first absorption spectrum, such as a first

absorption spectrum defined by a first dye, and the optical sensors 112 of the second type may have a second spectral sensitivity different from the first spectral sensitivity, such as a second absorption spectrum, such as a second absorption spectrum defined by a second dye. By evaluating sensor signals of these two or more types of optical sensors 112, color information may be obtained. Thus, in addition to the beam parameters which may be derived, the two or more types of optical sensors 112 may allow for deriving additional color information, such as for deriving a full-color three-dimensional image. Thus, as an example, color information may be derived by comparing the sensor signals of the optical sensors 112 of different color with values stored in a look-up table. Thus, the setup of Figure 6 may be embodied as a monochrome, a full-color or multicolor light-field camera.

As outlined above, the detector 110 may further comprise one or more time-of-flight detectors. This possibility is shown in Figure 7. The detector 110, firstly, comprises at least one component comprising the one or more pixelated optical sensors 112, such as a sensor stack 148. In the embodiment shown in Figure 7, the at least one unit comprising the optical sensors 112 is denoted as a camera 111. It shall be noted, however, that other embodiments are feasible. For details of potential setups of the camera 111, reference may be made to the setups shown above, such as the embodiment shown in Figure 1, or other embodiments of the detector 110. Basically any setup of the detector 110 as disclosed above may also be used in the context of the embodiment shown in Figure 7.

Further, the detector 110 comprises at least one time-of-flight (ToF) detector 198. As shown in Figure 7, the ToF detector 198 may be connected to the evaluation device 126 of the detector 110 or may be provided with a separate evaluation device. As outlined above, the ToF detector 198 may be adapted, by emitting and receiving pulses 200, as symbolically depicted in Figure 7, to determine a distance between the detector 110 and the object 118 or, in other words, a z-coordinate along the optical axis 142.

The at least one optional ToF detector 198 may be combined with the at least one detector having the pixelated optical sensors 112 such as the camera 111 in various ways. Thus, as an example and as shown in Figure 7, the at least one camera 111 may be located in a first partial beam path 202, and the ToF detector 198 may be located in a second partial beam path 204. The partial beam paths 202, 204 may be separated and/or combined by at least one beam-splitting element 206. As an example, the beam-splitting element 206 may be a wavelength-indifferent beam-splitting element 206, such as a semi-transparent mirror. Additionally or alternatively, a wavelength-dependency may be provided, thereby allowing for separating different wavelengths. As an alternative, or in addition to the setup shown in Figure 7, other setups of the ToF detector 198 may be used. Thus, the camera 111 and the ToF detector 198 may be arranged in line, such as by arranging the ToF detector 198 behind the camera 111. In this case, preferably, no intransparent optical sensor is provided in the camera 111, and all optical sensors 112 are at least partially transparent. Again, as an alternative or in addition, the ToF detector 198 may also be arranged independently from the camera 111, and different light paths may be used, without combining the light paths. Various setups are feasible.

As outlined above, the ToF detector 198 and the camera 111 may be combined in a beneficial way, for various purposes, such as for resolving ambiguities, for increasing the range of weather conditions in which the optical detector 110 may be used, or for extending a distance range between the object 118 and the optical detector 110. For further details, reference may be made to the description above.

Patent claims

1. A detector (110) for determining a position of at least one object (118), the detector (110) comprising:
 - 5 - at least one optical sensor (112), the optical sensor (112) being adapted to detect a light beam (150) traveling from the object (118) towards the detector (110), the optical sensor (112) having at least one matrix (152) of pixels (154); and
 - 10 - at least one evaluation device (126), the evaluation device (126) being adapted to determine a number N of pixels (154) of the optical sensor (112) which are illuminated by the light beam (150), the evaluation device (126) further being adapted to determine at least one longitudinal coordinate of the object (118) by using the number N of pixels (154) which are illuminated by the light beam (150).
- 15 2. The detector (110) according to the preceding claim, wherein the optical sensor (112) is adapted to generate at least one signal indicating an intensity of illumination for each of the pixels (154).
- 20 3. The detector (110) according to the preceding claim, wherein the evaluation device (126) is adapted to compare, for each of the pixels (154), the signal to at least one threshold in order to determine whether the pixel is an illuminated pixel or not.
- 25 4. The detector (110) according to the preceding claim, wherein the evaluation device (126) is adapted to determine at least one pixel having the highest illumination out of the pixels (154) by comparing the signals of the pixels (154).
5. The detector (110) according to the preceding claim, wherein the evaluation device (126) is further adapted to choose the threshold as a fraction of the signal of the at least one pixel having the highest illumination.
- 30 6. The detector (110) according to the preceding claim, wherein the evaluation device (126) is adapted to choose the threshold by multiplying the signal of the at least one pixel having the highest illumination with a factor of $1/e^2$.
- 35 7. The detector (110) according to any one of the preceding claims, wherein the evaluation device (126) is adapted to determine the longitudinal coordinate of the object (118) by using a predetermined relationship between the number N of pixels (154) which are illuminated by the light beam (150) and the longitudinal coordinate.
- 40 8. The detector (110) according to the preceding claim, wherein the predetermined relationship is based on the assumption of the light beam (150) being a Gaussian light beam (150).

9. The detector (110) according to any one of the two preceding claims, wherein the predetermined relationship is

$$N \sim \pi \cdot w_0^2 \cdot \left(1 + \left(\frac{z}{z_0}\right)^2\right),$$

5

wherein z is the longitudinal coordinate,
 wherein w_0 is a minimum beam radius of the light beam (150) when propagating in space,
 wherein z_0 is a Rayleigh-length of the light beam (150) with $z_0 = \pi \cdot w_0^2 / \lambda$, λ being the
 wavelength of the light beam (150).

10

10. The detector (110) according to any one of the preceding claims, wherein the detector (110) comprises a plurality of the optical sensors (112).

15

11. The detector (110) according to the preceding claim, wherein the detector (110) comprises n optical sensors (112), wherein the evaluation device (126) is adapted to determine the number N_i of pixels (154) which are illuminated by the light beam (150) for each of the optical sensors (112), wherein $i \in \{1, n\}$ denotes the respective optical sensor (112).

20

12. The detector (110) according to any one of the two preceding claims, wherein the evaluation device (126) is adapted to compare the number N_i of pixels (154) which are illuminated by the light beam (150) for each optical sensor (112) with at least one neighboring optical sensor (112), thereby resolving an ambiguity in the longitudinal coordinate of the object (118).

25

13. The detector (110) according to any one of the three preceding claims, wherein at least one of the optical sensors (112) is transparent.

30

14. The detector (110) according to any one of the four preceding claims, wherein at least two of the optical sensors (112) have a differing spectral sensitivity, wherein the evaluation device (126) is adapted to determine a color of the light beam (150) by comparing sensor signals of the optical sensors (112) having the differing spectral sensitivity.

35

15. The detector (110) according to any one of the preceding claims, wherein the evaluation device (126) is further adapted to determine at least one transversal coordinate of the object (118) by determining a position of the light beam (150) on the matrix (152) of pixels (154).

40

16. The detector (110) according to any one of the preceding claims, wherein the detector (110) further comprises at least one transfer device (136), the transfer device (136) being adapted to guide the light beam (150) onto the optical sensor (112).

17. The detector (110) according to any one of the preceding claims, wherein the optical sensor (112) comprises at least one first electrode (180), at least one second electrode (188) and at least one light-sensitive layer (184) embedded in between the first electrode (180) and the second electrode (188), wherein the first electrode (180) comprises a plurality of first electrode stripes (182) and wherein the second electrode (188) comprises a plurality of second electrode stripes (190), wherein the first electrode stripes (182) are oriented perpendicular to the second electrode stripes (190).
18. A detector system (114) for determining a position of at least one object (118), the detector system (114) comprising at least one detector (110) according to any one of the preceding claims, the detector system (114) further comprising at least one beacon device (116) adapted to direct at least one light beam (150) towards the detector (110), wherein the beacon device (116) is at least one of attachable to the object (118), holdable by the object (118) and integratable into the object (118).
19. A human-machine interface (120) for exchanging at least one item of information between a user (134) and a machine (176), wherein the human-machine interface (120) comprises at least one detector system (114) according to the preceding claim, wherein the at least one beacon device (116) is adapted to be at least one of directly or indirectly attached to the user (134) and held by the user (134), wherein the human-machine interface (120) is designed to determine at least one position of the user (134) by means of the detector system (114), wherein the human-machine interface (120) is designed to assign to the position at least one item of information.
20. An entertainment device (122) for carrying out at least one entertainment function, wherein the entertainment device (122) comprises at least one human-machine interface (120) according to the preceding claim, wherein the entertainment device (122) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (120), wherein the entertainment device (122) is designed to vary the entertainment function in accordance with the information.
21. A tracking system (124) for tracking a position of at least one movable object (118), the tracking system (124) comprising at least one detector system (114) according to any one of the preceding claims referring to a detector system (114), the tracking system (124) further comprising at least one track controller (172), wherein the track controller (172) is adapted to track a series of positions of the object (118) at specific points in time.
22. A camera (111) for imaging at least one object (118), the camera (111) comprising at least one detector (110) according to any one of the preceding claims referring to a detector (110).

23. A method for determining a position of at least one object (118), the method comprising the following steps:
- at least one detection step, wherein at least one light beam (150) traveling from the object (118) to a detector (110) is detected by at least one optical sensor (112) of the detector (110), the at least one optical sensor (112) having at least one matrix (152) of pixels (154); and
 - at least one evaluation step, wherein a number N of pixels (154) of the optical sensor (112) is determined which are illuminated by the light beam (150), wherein at least one longitudinal coordinate of the object (118) is determined by using the number N of pixels (154) which are illuminated by the light beam (150).
24. A use of the detector (110) according to any one of the preceding claims relating to a detector (110), for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a safety application; a human-machine interface (120) application; a tracking application; a photography application; a use in combination with at least one time-of-flight detector (198).

- ☒ Box No. VIII Certain observations on the international application

2. FURTHER ACTION

If a demand for international preliminary examination is made, this opinion will usually be considered to be a written opinion of the International Preliminary Examining Authority ("IPEA") except that this does not apply where the applicant chooses an Authority other than this one to be the IPEA and the chosen IPEA has notified the International Bureau under Rule 66.1bis(b) that written opinions of this International Searching Authority will not be so considered.

If this opinion is, as provided above, considered to be a written opinion of the IPEA, the applicant is invited to submit to the IPEA a written reply together, where appropriate, with amendments, before the expiration of 3 months from the date of mailing of Form PCT/ISA/220 or before the expiration of 22 months from the priority date, whichever expires later.

For further options, see Form PCT/ISA/220.

Box No. I Basis of the opinion

1. With regard to the **language**, this opinion has been established on the basis of:
 - ☒ the international application in the language in which it was filed.
 - ☐ a translation of the international application into , which is the language of a translation furnished for the purposes of international search (Rules 12.3(a) and 23.1 (b)).
2. ☐ This opinion has been established taking into account the **rectification of an obvious mistake** authorized by or notified to this Authority under Rule 91 (Rule 43*bis*.1(a))
3. ☐ With regard to any **nucleotide and/or amino acid sequence** disclosed in the international application, this opinion has been established on the basis of a sequence listing:
 - a. ☐ forming part of the international application as filed:
 - ☐ in the form of an Annex C/ST.25 text file.
 - ☐ on paper or in the form of an image file.
 - b. ☐ furnished together with the international application under PCT Rule 13*ter*.1(a) for the purposes of international search only in the form of an Annex C/ST.25 text file.
 - c. ☐ furnished subsequent to the international filing date for the purposes of international search only:
 - ☐ in the form of an Annex C/ST.25 text file (Rule 13*ter*.1(a)).
 - ☐ on paper or in the form of an image file (Rule 13*ter*.1(b) and Administrative Instructions, Section 713).
4. ☐ In addition, in the case that more than one version or copy of a sequence listing has been filed or furnished, the required statements that the information in the subsequent or additional copies is identical to that forming part of the application as filed or does not go beyond the application as filed, as appropriate, were furnished.
5. Additional comments:

The following observations on the clarity of the claims, description, and drawings or on the question whether the claims are fully supported by the description, are made:

see separate sheet

Re Item V

Reasoned statement with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

Reference is made to the following documents:

- D1 DE 198 46 619 A1 (BYK GARDNER GMBH [DE]) 27 April 2000 (2000-04-27)
- D2 CN 108 363 482 A (JIANGSU SIDIANLING ROBOT CO LTD) 3 August 2018 (2018-08-03)
- D3 US 2018/033146 A1 (BLEYER MICHAEL [US] ET AL) 1 February 2018 (2018-02-01)
- D4 WO 2019/042956 A1 (TRINAMIX GMBH [DE]) 7 March 2019 (2019-03-07)

- 1 The present application does not meet the criteria of Article 33(1) PCT, because the subject-matter of independent claims 1, 24 and 25 is not new in the sense of Article 33(2) PCT.

Claim 1

A detector for identifying at least one material property comprising

- at least one sensor element comprising a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein the sensor element is configured for recording at least one reflection image of a light beam originating from at least one object (D1: claim 1; D2: claim 1 - camera; D3: claim 1, claim 11 - imaging system)

- at least one evaluation device configured for determining the material property by evaluation of at least one beam profile of the reflection image (D1: claim 1; D2: claim 1 - processor, depth information; D3: claim 1, claim 11 - intensity profile determination),

wherein the evaluation device is configured for determining at least one distance feature by applying at least one distance dependent image filter to the reflection image, wherein the distance dependent image filter is at least one filter selected from the group consisting of: a depth-from-photon-ratio filter; a depth-from-defocus filter; or a linear combination thereof; or a further distance dependent image filter which correlates to the depth-from-photon-ratio filter and/or the depth-from-defocus filter or a linear combination thereof, being one of the

depth-from-photon-ratio filter or the depth-from-defocus filter or a linear combination thereof, (D1: claim 29; D2: claim 1 - triangulation; D3: claims 1, 4 - depth map, triangulation)

wherein the evaluation device is configured for determining at least one material feature by applying at least one material dependent image filter to the reflection image, wherein the material dependent image filter is at least one filter selected from the group consisting of: a luminance filter; a spot shape filter; a squared norm gradient; a standard deviation; a smoothness filter such as a Gaussian filter or median filter; a grey-level-occurrence-based contrast filter; a grey-level-occurrence-based energy filter; a grey-level-occurrence-based homogeneity filter; a grey-level-occurrence-based dissimilarity filter; a Law's energy filter; a threshold area filter; or a linear combination thereof; or a further material dependent image filter Mother which correlates to one or more of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof, being one of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof (D1: claim 1, col. 14, l. 38-66; D2: claim 1 - median filter; D3: claim 6, [0036]),

wherein the evaluation device is configured for determining a longitudinal coordinate and the material property by evaluating the distance feature and the material feature (D1: claims 1 and 29; D2: claim 1 - median filtering, processing depth image; D3: claim 6, [0037]).

The method according to **claim 24** is disclosed in the same manner.

Claim 25

A use of the detector according to any one of the preceding claims relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a logistics application; a tracking application; an outdoor application; a mobile application; a communication application; a photography

- application; a machine vision application; a robotics application; a quality control application; a manufacturing application (D1: col 2, l. 31-38; D2: claim 1; D3: [0013]).
- 2 The present application does not meet the criteria of Article 33(1) PCT, because the subject-matter of independent **claim 23** does not involve an inventive step in the sense of Article 33(3) PCT.
- Inertial measurement units are generally known, being adapted to receive data of a sensor as defined in claim 1, a material property detector, does not allow to establish a technical effect resulting from this feature.
- 3 The dependent claims do not contain particular features which appear suitable for rendering the independent claims clear, new and defining inventive subject matter:
- Claims 2, 3, 5-7 relate to further vague definitions of the filters, not adding any more substance.
- Claim 4 relates to material properties usually determined: e.g. D1: column 14, lines 38-45; D3: claim 1.
- Claim 8: see D3, claim 6
- Claims 9-11: Recursive, iterative or simultaneous application of filters and applying a further filter are considered usual alternatives.
- Claims 12, 13: Using combined signals from sensor elements or a convolution based algorithm are considered common measures.
- Claim 14: A CMOS sensor is a common matrix sensor.
- Claim 15: D1, claim 7
- Claim 16: A diffractive optical element is a usual means for producing such patterns.
- The features of claims 17-20 are known from D4, claims 19-22, which the skilled person would turn to in order to find implementations.
- Claim 21: D2, claim 1
- Claim 22: D3, claim 1

Re Item VIII

Certain observations on the international application

The claims are not clear (Article 6 PCT) and the disclosure of the invention defined therein is not sufficient for enabling the skilled person to carry it out (Article 5 PCT).

The independent claims 1 and 24 relate to determining a longitudinal coordinate and a material property. It is neither clear how it is arrived at the desired distance feature and material feature nor which "further" filters are covered by the claim. The vague indication of correlation with one of the listed filters is an infinite definition of filters which does not allow to put into practice the invention or determine what is covered by the claims. The list of filters contains filters which are not commonly known and lack a definition in the claims.

The sign φ_{1m} in claim 10 is not defined.

Claim 23: As the detector as defined in claim 1 determines a material property, it is not clear how it can be used in an inertial measurement unit. A disclosure in this respect is also missing in the description.

-------------------------------------	--	--	----------

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for a filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application.

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

Receipt is acknowledged of this non-provisional utility patent application. The application will be taken up for examination in due course. Applicant will be notified as to the results of the examination. Any correspondence concerning the application must include the following identification information: the U.S. APPLICATION NUMBER, FILING DATE, NAME OF FIRST INVENTOR, and TITLE OF INVENTION. Fees transmitted by check or draft are subject to collection.

Please verify the accuracy of the data presented on this receipt. If an error is noted on this Filing Receipt, please submit a written request for a corrected Filing Receipt, including a properly marked-up ADS showing the changes with strike-through for deletions and underlining for additions. If you received a "Notice to File Missing Parts" or other Notice requiring a response for this application, please submit any request for correction to this Filing Receipt with your reply to the Notice. When the USPTO processes the reply to the Notice, the USPTO will generate another Filing Receipt incorporating the requested corrections provided that the request is grantable.

PROTECTING YOUR INVENTION OUTSIDE THE UNITED STATES

Since the rights granted by a U.S. patent extend only throughout the territory of the United States and have no effect in a foreign country, an inventor who wishes patent protection in another country must apply for a patent in a specific country or in regional patent offices. Applicants may wish to consider the filing of an international application under the Patent Cooperation Treaty (PCT). An international (PCT) application generally has the same effect as a regular national patent application in each PCT-member country. The PCT process **simplifies** the filing of patent applications on the same invention in member countries, but **does not result** in a grant of "an international patent" and does not eliminate the need of applicants to file additional documents and fees in countries where patent protection is desired.

Almost every country has its own patent law, and a person desiring a patent in a particular country must make an application for patent in that country in accordance with its particular laws. Since the laws of many countries differ in various respects from the patent law of the United States, applicants are advised to seek guidance from specific foreign countries to ensure that patent rights are not lost prematurely.

Applicants also are advised that in the case of inventions made in the United States, the Director of the USPTO must issue a license before applicants can apply for a patent in a foreign country. The filing of a U.S. patent application serves as a request for a foreign filing license. The application's filing receipt contains further information and guidance as to the status of applicant's license for foreign filing.

Applicants may wish to consult the USPTO booklet, "General Information Concerning Patents" (specifically, the section entitled "Treaties and Foreign Patents") for more information on timeframes and deadlines for filing foreign patent applications. The guide is available either by contacting the USPTO Contact Center at 800-786-9199, or it can be viewed on the USPTO website at <http://www.uspto.gov/web/offices/pac/doc/general/index.html>.

For information on preventing theft of your intellectual property (patents, trademarks and copyrights), you may wish to consult the U.S. Government website, <http://www.stopfakes.gov>. Part of a Department of Commerce initiative, this website includes self-help "toolkits" giving innovators guidance on how to protect intellectual property in specific countries such as China, Korea and Mexico. For questions regarding patent enforcement issues, applicants may call the U.S. Government hotline at 1-866-999-HALT (1-866-999-4258).

LICENSE FOR FOREIGN FILING UNDER

Title 35, United States Code, Section 184

Title 37, Code of Federal Regulations, 5.11 & 5.15

GRANTED

The applicant has been granted a license under 35 U.S.C. 184, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" followed by a date appears on this form. Such licenses are issued in all applications where the conditions for issuance of a license have been met, regardless of whether or not a license may be required as set forth in 37 CFR 5.15. The scope and limitations of this license are set forth in 37 CFR 5.15(a) unless an earlier license has been issued under 37 CFR 5.15(b). The license is subject to revocation upon written notification. The date indicated is the effective date of the license, unless an earlier license of similar scope has been granted under 37 CFR 5.13 or 5.14.

This license is to be retained by the licensee and may be used at any time on or after the effective date thereof unless it is revoked. This license is automatically transferred to any related applications(s) filed under 37 CFR 1.53(d). This license is not retroactive.

The grant of a license does not in any way lessen the responsibility of a licensee for the security of the subject matter as imposed by any Government contract or the provisions of existing laws relating to espionage and the national security or the export of technical data. Licensees should apprise themselves of current regulations especially with respect to certain countries, of other agencies, particularly the Office of Defense Trade Controls, Department of State (with respect to Arms, Munitions and Implements of War (22 CFR 121-128)); the Bureau of Industry and Security, Department of Commerce (15 CFR parts 730-774); the Office of Foreign Assets Control, Department of Treasury (31 CFR Parts 500+) and the Department of Energy.

NOT GRANTED

No license under 35 U.S.C. 184 has been granted at this time, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" DOES NOT appear on this form. Applicant may still petition for a license under 37 CFR 5.12, if a license is desired before the expiration of 6 months from the filing date of the application. If 6 months has lapsed from the filing date of this application and the licensee has not received any indication of a secrecy order under 35 U.S.C. 181, the licensee may foreign file the application pursuant to 37 CFR 5.15(b).

SelectUSA

The United States represents the largest, most dynamic marketplace in the world and is an unparalleled location for business investment, innovation, and commercialization of new technologies. The U.S. offers tremendous resources and advantages for those who invest and manufacture goods here. Through SelectUSA, our nation works to promote and facilitate business investment. SelectUSA provides information assistance to the international investor

community; serves as an ombudsman for existing and potential investors; advocates on behalf of U.S. cities, states, and regions competing for global investment; and counsels U.S. economic development organizations on investment attraction best practices. To learn more about why the United States is the best country in the world to develop technology, manufacture products, deliver services, and grow your business, visit <http://www.SelectUSA.gov> or call +1-202-482-6800.

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Application of: Friedrich Schick et al.

Serial No.: 17/439,492

Filed: September 15, 2021

Confirmation No.: 9002

For: DETECTOR FOR IDENTIFYING AT LEAST ONE MATERIAL PROPERTY

February 9, 2022

To The Commissioner for Patents,

Sir:

REQUEST FOR CORRECTED FILING RECEIPT

Applicant respectfully requests that the Filing Receipt in the above-referenced application be corrected to reflect the correct spelling of the applicant as shown on the Application Data Sheet.

A marked-up copy of the Filing Receipt reflecting the requested change, and the Application Data Sheet (ADS) as filed on September 15, 2021 showing the correct spelling, are attached.

Applicants further request that a new, corrected filing receipt be issued.

Since this was a Patent Office error it is believed that no fee is due. The Commissioner is hereby authorized to charge any deficiency or credit any overpayment of fees for this Request to Deposit Account No. 012384.

Respectfully submitted,

/Christopher M. Goff/

Receipt is acknowledged of this non-provisional utility patent application. The application will be taken up for examination in due course. Applicant will be notified as to the results of the examination. Any correspondence concerning the application must include the following identification information: the U.S. APPLICATION NUMBER, FILING DATE, NAME OF FIRST INVENTOR, and TITLE OF INVENTION. Fees transmitted by check or draft are subject to collection.

Please verify the accuracy of the data presented on this receipt. If an error is noted on this Filing Receipt, please submit a written request for a corrected Filing Receipt, including a properly marked-up ADS showing the changes with strike-through for deletions and underlining for additions. If you received a "Notice to File Missing Parts" or other Notice requiring a response for this application, please submit any request for correction to this Filing Receipt with your reply to the Notice. When the USPTO processes the reply to the Notice, the USPTO will generate another Filing Receipt incorporating the requested corrections provided that the request is grantable.

DETECTOR FOR IDENTIFYING AT LEAST ONE MATERIAL PROPERTY

Preliminary Class

Statement under 37 CFR 1.55 or 1.78 for AIA (First Inventor to File) Transition Applications: No

PROTECTING YOUR INVENTION OUTSIDE THE UNITED STATES

Since the rights granted by a U.S. patent extend only throughout the territory of the United States and have no effect in a foreign country, an inventor who wishes patent protection in another country must apply for a patent in a specific country or in regional patent offices. Applicants may wish to consider the filing of an international application under the Patent Cooperation Treaty (PCT). An international (PCT) application generally has the same effect as a regular national patent application in each PCT-member country. The PCT process **simplifies** the filing of patent applications on the same invention in member countries, but **does not result** in a grant of "an international patent" and does not eliminate the need of applicants to file additional documents and fees in countries where patent protection is desired.

Almost every country has its own patent law, and a person desiring a patent in a particular country must make an application for patent in that country in accordance with its particular laws. Since the laws of many countries differ in various respects from the patent law of the United States, applicants are advised to seek guidance from specific foreign countries to ensure that patent rights are not lost prematurely.

Applicants also are advised that in the case of inventions made in the United States, the Director of the USPTO must issue a license before applicants can apply for a patent in a foreign country. The filing of a U.S. patent application serves as a request for a foreign filing license. The application's filing receipt contains further information and guidance as to the status of applicant's license for foreign filing.

Applicants may wish to consult the USPTO booklet, "General Information Concerning Patents" (specifically, the section entitled "Treaties and Foreign Patents") for more information on timeframes and deadlines for filing foreign patent applications. The guide is available either by contacting the USPTO Contact Center at 800-786-9199, or it can be viewed on the USPTO website at <http://www.uspto.gov/web/offices/pac/doc/general/index.html>.

For information on preventing theft of your intellectual property (patents, trademarks and copyrights), you may wish to consult the U.S. Government website, <http://www.stopfakes.gov>. Part of a Department of Commerce initiative, this website includes self-help "toolkits" giving innovators guidance on how to protect intellectual property in specific countries such as China, Korea and Mexico. For questions regarding patent enforcement issues, applicants may call the U.S. Government hotline at 1-866-999-HALT (1-866-999-4258).

LICENSE FOR FOREIGN FILING UNDER

Title 35, United States Code, Section 184

Title 37, Code of Federal Regulations, 5.11 & 5.15

GRANTED

The applicant has been granted a license under 35 U.S.C. 184, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" followed by a date appears on this form. Such licenses are issued in all applications where the conditions for issuance of a license have been met, regardless of whether or not a license may be required as set forth in 37 CFR 5.15. The scope and limitations of this license are set forth in 37 CFR 5.15(a) unless an earlier license has been issued under 37 CFR 5.15(b). The license is subject to revocation upon written notification. The date indicated is the effective date of the license, unless an earlier license of similar scope has been granted under 37 CFR 5.13 or 5.14.

This license is to be retained by the licensee and may be used at any time on or after the effective date thereof unless it is revoked. This license is automatically transferred to any related applications(s) filed under 37 CFR 1.53(d). This license is not retroactive.

The grant of a license does not in any way lessen the responsibility of a licensee for the security of the subject matter as imposed by any Government contract or the provisions of existing laws relating to espionage and the national security or the export of technical data. Licensees should apprise themselves of current regulations especially with respect to certain countries, of other agencies, particularly the Office of Defense Trade Controls, Department of State (with respect to Arms, Munitions and Implements of War (22 CFR 121-128)); the Bureau of Industry and Security, Department of Commerce (15 CFR parts 730-774); the Office of Foreign Assets Control, Department of Treasury (31 CFR Parts 500+) and the Department of Energy.

NOT GRANTED

No license under 35 U.S.C. 184 has been granted at this time, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" DOES NOT appear on this form. Applicant may still petition for a license under 37 CFR 5.12, if a license is desired before the expiration of 6 months from the filing date of the application. If 6 months has lapsed from the filing date of this application and the licensee has not received any indication of a secrecy order under 35 U.S.C. 181, the licensee may foreign file the application pursuant to 37 CFR 5.15(b).

SelectUSA

The United States represents the largest, most dynamic marketplace in the world and is an unparalleled location for business investment, innovation, and commercialization of new technologies. The U.S. offers tremendous resources and advantages for those who invest and manufacture goods here. Through SelectUSA, our nation works to promote and facilitate business investment. SelectUSA provides information assistance to the international investor

community; serves as an ombudsman for existing and potential investors; advocates on behalf of U.S. cities, states, and regions competing for global investment; and counsels U.S. economic development organizations on investment attraction best practices. To learn more about why the United States is the best country in the world to develop technology, manufacture products, deliver services, and grow your business, visit <http://www.SelectUSA.gov> or call +1-202-482-6800.

Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it contains a valid OMB control number.

Foreign Priority Information:

This section allows for the applicant to claim priority to a foreign application. Providing this information in the application data sheet constitutes the claim for priority as required by 35 U.S.C. 119(b) and 37 CFR 1.55. When priority is claimed to a foreign application that is eligible for retrieval under the priority document exchange program (PDX)ⁱ the information will be used by the Office to automatically attempt retrieval pursuant to 37 CFR 1.55(i)(1) and (2). Under the PDX program, applicant bears the ultimate responsibility for ensuring that a copy of the foreign application is received by the Office from the participating foreign intellectual property office, or a certified copy of the foreign priority application is filed, within the time period specified in 37 CFR 1.55(g)(1).

Authorization or Opt-Out of Authorization to Permit Access:

When this Application Data Sheet is properly signed and filed with the application, applicant has provided written authority to permit a participating foreign intellectual property (IP) office access to the instant application-as-filed (see paragraph A in subsection 1 below) and the European Patent Office (EPO) access to any search results from the instant application (see paragraph B in subsection 1 below).

Should applicant choose not to provide an authorization identified in subsection 1 below, applicant **must opt-out** of the authorization by checking the corresponding box A or B or both in subsection 2 below.

NOTE: This section of the Application Data Sheet is **ONLY** reviewed and processed with the **INITIAL** filing of an application. After the initial filing of an application, an Application Data Sheet cannot be used to provide or rescind authorization for access by a foreign IP office(s). Instead, Form PTO/SB/39 or PTO/SB/69 must be used as appropriate.

1. Authorization to Permit Access by a Foreign Intellectual Property Office(s)

A. Priority Document Exchange (PDX) - Unless box A in subsection 2 (opt-out of authorization) is checked, the undersigned hereby **grants the USPTO authority** to provide the European Patent Office (EPO), the Japan Patent Office (JPO), the Korean Intellectual Property Office (KIPO), the State Intellectual Property Office of the People's Republic of China (SIPO), the World Intellectual Property Organization (WIPO), and any other foreign intellectual property office participating with the USPTO in a bilateral or multilateral priority document exchange agreement in which a foreign application claiming priority to the instant patent application is filed, access to: (1) the instant patent application-as-filed and its related bibliographic data, (2) any foreign or domestic application to which priority or benefit is claimed by the instant application and its related bibliographic data, and (3) the date of filing of this Authorization. See 37 CFR 1.14(h)(1).

B. Search Results from U.S. Application to EPO - Unless box B in subsection 2 (opt-out of authorization) is checked, the undersigned hereby **grants the USPTO authority** to provide the EPO access to the bibliographic data and search results from the instant patent application when a European patent application claiming priority to the instant patent application is filed. See 37 CFR 1.14(h)(2).

The applicant is reminded that the EPO's Rule 141(1) EPC (European Patent Convention) requires applicants to submit a copy of search results from the instant application without delay in a European patent application that claims priority to the instant application.

2. Opt-Out of Authorizations to Permit Access by a Foreign Intellectual Property Office(s)

☐ A. Applicant **DOES NOT** authorize the USPTO to permit a participating foreign IP office access to the instant application-as-filed. If this box is checked, the USPTO will not be providing a participating foreign IP office with any documents and information identified in subsection 1A above.

☐ B. Applicant **DOES NOT** authorize the USPTO to transmit to the EPO any search results from the instant patent application. If this box is checked, the USPTO will not be providing the EPO with search results from the instant application.

NOTE: Once the application has published or is otherwise publicly available, the USPTO may provide access to the application in accordance with 37 CFR 1.14.

Application Data Sheet 37 CFR 1.76		Attorney Docket Number	27843-1809 182037US01
		Application Number	
Title of Invention	DETECTOR FOR IDENTIFYING AT LEAST ONE MATERIAL PROPERTY		

Applicant Information:

Providing assignment information in this section does not substitute for compliance with any requirement of part 3 of Title 37 of CFR to have an assignment recorded by the Office.

Applicant 1

If the applicant is the inventor (or the remaining joint inventor or inventors under 37 CFR 1.45), this section should not be completed. The information to be provided in this section is the name and address of the legal representative who is the applicant under 37 CFR 1.43; or the name and address of the assignee, person to whom the inventor is under an obligation to assign the invention, or person who otherwise shows sufficient proprietary interest in the matter who is the applicant under 37 CFR 1.46. If the applicant is an applicant under 37 CFR 1.46 (assignee, person to whom the inventor is obligated to assign, or person who otherwise shows sufficient proprietary interest) together with one or more joint inventors, then the joint inventor or inventors who are also the applicant should be identified in this section.

[Clear](#)

☒ Assignee
 ☐ Legal Representative under 35 U.S.C. 117
 ☐ Joint Inventor

☐ Person to whom the inventor is obligated to assign.
 ☐ Person who shows sufficient proprietary interest

If applicant is the legal representative, indicate the authority to file the patent application, the inventor is:

This collection of information is required by 37 CFR 1.76. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 23 minutes to complete, including gathering, preparing, and submitting the completed application data sheet form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

- 1 The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these records.
- 2 A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
- 3 A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
- 4 A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
- 5 A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
- 6 A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
- 7 A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
- 8 A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.
- 9 A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

Receipt is acknowledged of this non-provisional utility patent application. The application will be taken up for examination in due course. Applicant will be notified as to the results of the examination. Any correspondence concerning the application must include the following identification information: the U.S. APPLICATION NUMBER, FILING DATE, NAME OF FIRST INVENTOR, and TITLE OF INVENTION. Fees transmitted by check or draft are subject to collection.

Please verify the accuracy of the data presented on this receipt. If an error is noted on this Filing Receipt, please submit a written request for a corrected Filing Receipt, including a properly marked-up ADS showing the changes with strike-through for deletions and underlining for additions. If you received a "Notice to File Missing Parts" or other Notice requiring a response for this application, please submit any request for correction to this Filing Receipt with your reply to the Notice. When the USPTO processes the reply to the Notice, the USPTO will generate another Filing Receipt incorporating the requested corrections provided that the request is grantable.

Statement under 37 CFR 1.55 or 1.78 for AIA (First Inventor to File) Transition Applications: No

PROTECTING YOUR INVENTION OUTSIDE THE UNITED STATES

Since the rights granted by a U.S. patent extend only throughout the territory of the United States and have no effect in a foreign country, an inventor who wishes patent protection in another country must apply for a patent in a specific country or in regional patent offices. Applicants may wish to consider the filing of an international application under the Patent Cooperation Treaty (PCT). An international (PCT) application generally has the same effect as a regular national patent application in each PCT-member country. The PCT process **simplifies** the filing of patent applications on the same invention in member countries, but **does not result** in a grant of "an international patent" and does not eliminate the need of applicants to file additional documents and fees in countries where patent protection is desired.

Almost every country has its own patent law, and a person desiring a patent in a particular country must make an application for patent in that country in accordance with its particular laws. Since the laws of many countries differ in various respects from the patent law of the United States, applicants are advised to seek guidance from specific foreign countries to ensure that patent rights are not lost prematurely.

Applicants also are advised that in the case of inventions made in the United States, the Director of the USPTO must issue a license before applicants can apply for a patent in a foreign country. The filing of a U.S. patent application serves as a request for a foreign filing license. The application's filing receipt contains further information and guidance as to the status of applicant's license for foreign filing.

Applicants may wish to consult the USPTO booklet, "General Information Concerning Patents" (specifically, the section entitled "Treaties and Foreign Patents") for more information on timeframes and deadlines for filing foreign patent applications. The guide is available either by contacting the USPTO Contact Center at 800-786-9199, or it can be viewed on the USPTO website at <http://www.uspto.gov/web/offices/pac/doc/general/index.html>.

For information on preventing theft of your intellectual property (patents, trademarks and copyrights), you may wish to consult the U.S. Government website, <http://www.stopfakes.gov>. Part of a Department of Commerce initiative, this website includes self-help "toolkits" giving innovators guidance on how to protect intellectual property in specific countries such as China, Korea and Mexico. For questions regarding patent enforcement issues, applicants may call the U.S. Government hotline at 1-866-999-HALT (1-866-999-4258).

LICENSE FOR FOREIGN FILING UNDER

Title 35, United States Code, Section 184

Title 37, Code of Federal Regulations, 5.11 & 5.15

GRANTED

The applicant has been granted a license under 35 U.S.C. 184, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" followed by a date appears on this form. Such licenses are issued in all applications where the conditions for issuance of a license have been met, regardless of whether or not a license may be required as set forth in 37 CFR 5.15. The scope and limitations of this license are set forth in 37 CFR 5.15(a) unless an earlier license has been issued under 37 CFR 5.15(b). The license is subject to revocation upon written notification. The date indicated is the effective date of the license, unless an earlier license of similar scope has been granted under 37 CFR 5.13 or 5.14.

This license is to be retained by the licensee and may be used at any time on or after the effective date thereof unless it is revoked. This license is automatically transferred to any related applications(s) filed under 37 CFR 1.53(d). This license is not retroactive.

The grant of a license does not in any way lessen the responsibility of a licensee for the security of the subject matter as imposed by any Government contract or the provisions of existing laws relating to espionage and the national security or the export of technical data. Licensees should apprise themselves of current regulations especially with respect to certain countries, of other agencies, particularly the Office of Defense Trade Controls, Department of State (with respect to Arms, Munitions and Implements of War (22 CFR 121-128)); the Bureau of Industry and Security, Department of Commerce (15 CFR parts 730-774); the Office of Foreign Assets Control, Department of Treasury (31 CFR Parts 500+) and the Department of Energy.

NOT GRANTED

No license under 35 U.S.C. 184 has been granted at this time, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" DOES NOT appear on this form. Applicant may still petition for a license under 37 CFR 5.12, if a license is desired before the expiration of 6 months from the filing date of the application. If 6 months has lapsed from the filing date of this application and the licensee has not received any indication of a secrecy order under 35 U.S.C. 181, the licensee may foreign file the application pursuant to 37 CFR 5.15(b).

SelectUSA

The United States represents the largest, most dynamic marketplace in the world and is an unparalleled location for business investment, innovation, and commercialization of new technologies. The U.S. offers tremendous resources and advantages for those who invest and manufacture goods here. Through SelectUSA, our nation works to promote and facilitate business investment. SelectUSA provides information assistance to the international investor

community; serves as an ombudsman for existing and potential investors; advocates on behalf of U.S. cities, states, and regions competing for global investment; and counsels U.S. economic development organizations on investment attraction best practices. To learn more about why the United States is the best country in the world to develop technology, manufacture products, deliver services, and grow your business, visit <http://www.SelectUSA.gov> or call +1-202-482-6800.

Title:DETECTOR FOR IDENTIFYING AT LEAST ONE MATERIAL PROPERTY

Publication No.US-2022-0157044-A1

Publication Date:05/19/2022

NOTICE OF PUBLICATION OF APPLICATION

The above-identified application will be electronically published as a patent application publication pursuant to 37 CFR 1.211, et seq. The patent application publication number and publication date are set forth above.

The publication may be accessed through the USPTO's publically available Searchable Databases via the Internet at www.uspto.gov. The direct link to access the publication is currently <http://www.uspto.gov/patft/>.

The publication process established by the Office does not provide for mailing a copy of the publication to applicant. A copy of the publication may be obtained from the Office upon payment of the appropriate fee set forth in 37 CFR 1.19(a)(1). Orders for copies of patent application publications are handled by the USPTO's Public Records Division. The Public Records Division can be reached by telephone at (571) 272-3150 or (800) 972-6382, by facsimile at (571) 273-3250, by mail addressed to the United States Patent and Trademark Office, Public Records Division, Alexandria, VA 22313-1450 or via the Internet.

In addition, information on the status of the application, including the mailing date of Office actions and the dates of receipt of correspondence filed in the Office, may also be accessed via the Internet through the Patent Electronic Business Center at www.uspto.gov using the public side of the Patent Application Information and Retrieval (PAIR) system. The direct link to access this status information is currently <https://portal.uspto.gov/pair/PublicPair>. Prior to publication, such status information is confidential and may only be obtained by applicant using the private side of PAIR.

Further assistance in electronically accessing the publication, or about PAIR, is available by calling the Patent Electronic Business Center at 1-866-217-9197.

Office of Data Management, Application Assistance Unit (571) 272-4000, or (571) 272-4200, or 1-888-786-0101

(54) Title: DETECTOR FOR DETERMINING A POSITION OF AT LEAST ONE OBJECT

FIG.2

(57) Abstract: A detector (110) for determining a position of at least one object (112) is proposed. The detector (110) comprises -at least one sensor element (116) having a matrix (118) of optical sensors (120), the optical sensors (120) each having a light-sensitive area (122), wherein each optical sensor (120) is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area (122) by a reflection light beam (182) propagating from the object (112) to the detector (110), wherein the sensor element (116) is adapted to determine at least one reflection image (126); -at least one evaluation device (128), wherein the evaluation device (128) is adapted to select at least one reflection feature of the reflection image (126), wherein the evaluation device (128) is configured for determining at least one longitudinal region (130) of the selected reflection feature of the reflection image (134) by evaluating a combined signal Q from the sensor signals, wherein the evaluation device (128) is adapted to determine at least one

displacement region (132) in at least one reference image (134) corresponding to the longitudinal region (130), wherein the evaluation device (128) is adapted to match the selected reflection feature with at least one reference feature within the displacement region (132).

Detector for determining a position of at least one object

Description

5 Field of the invention

The invention relates to a detector and a method for determining a position of at least one object. The invention further relates to a human-machine interface for exchanging at least one item of information between a user and a machine, an entertainment device, a tracking system, a camera, a scanning system and various uses of the detector device. The devices, methods and uses according to the present invention specifically may be employed for example in various areas of daily life, gaming, traffic technology, production technology, security technology, photography such as digital photography or video photography for arts, documentation or technical purposes, medical technology or in the sciences. Further, the invention specifically may be used for scanning one or more objects and/or for scanning a scenery, such as for generating a depth profile of an object or of a scenery, e.g. in the field of architecture, metrology, archaeology, arts, medicine, engineering or manufacturing. However, other applications are also possible.

Prior art

Optical 3D sensing methods generally may determine unreliable results in case of environment causing multiple reflections, with biasing light sources, or reflective measurement objects. Furthermore, 3D sensing methods, such as triangulation methods using structured light or stereo cameras, with imaging capabilities often suffer from a high demand of computational power to solve correspondence problems. Necessary computational power may result in high costs for processors or Field Programmable Gate Arrays (FPGAs), for heat removal in view of ventilation requirements or water proof housing difficulties, for electrical power consumption, in particular in mobile devices, and, in addition, in measurement uncertainties. The high demand in computational power may be prohibitive to realize real-time applications, high framerates or even standards video speed frame rates of 25 frames per second.

A large number of optical devices are known from the prior art using triangulation imaging methods. For example, structured light methods or stereo methods are known. For example, passive stereo methods using two cameras in a fixed relative orientation or active stereo technologies, where an additional light projector is used. Another example is the structures light approach, where one light projector and one camera in a fixed relative orientation are used. In order to determine a depth image via triangulation, the correspondence problem has to be solved first. Therefore, in passive stereo camera techniques enough corresponding feature points have to be identified in both camera views. In structured light approaches correspondences between pre-stored and projected pseudo random light patterns have to be determined. For a robust solution of these correspondence problems computational imaging algorithms such as algorithms scaling approximately quadratically with the number of points in the projected point pattern have to be employed. In structured light methods, for example, using a stereo system comprising two detectors having a fixed relative distance, a light source projects a pat-

tern such as points, pseudo-random, random, non-periodic or irregular point patterns, or the like. Each of the detectors generates an image of a reflection pattern and an image analysis task is to identify corresponding features in the two images. Due to fixed relative position a corresponding feature point selected in one of the two images lies along an epipolar line in the other image. However, solving the so-called correspondence problem may be difficult. In stereo and triangulation systems, the distance of all feature points along the epipolar line have to have reasonable correspondence among each other. A correspondence decision cannot be made one after another. If one correspondence is wrong, this has implications for other feature points, such as invisibility. This usually yields quadratic scaling evaluation algorithms.

For example, US 2008/0240502 A1 and US 2010/0118123 A1 describe an apparatus for mapping an object including an illumination assembly, which includes a single transparency containing a fixed pattern of spots. A light source transilluminates the single transparency with optical radiation so as to project the pattern onto the object. An image capture assembly captures an image of the pattern that is projected onto the object using the single transparency. A processor processes the image captured by the image capture assembly as to reconstruct a three-dimensional map of the object.

US 2008/118143 A1 describes a method and apparatus for obtaining an image to determine a three dimensional shape of a stationary or moving object using a bi dimensional coded light pattern having a plurality of distinct identifiable feature types. The coded light pattern is projected on the object such that each of the identifiable feature types appears at most once on predefined sections of distinguishable epipolar lines. An image of the object is captured and the reflected feature types are extracted along with their location on known epipolar lines in the captured image. Displacements of the reflected feature types along their epipolar lines from reference coordinates thereupon determine corresponding three dimensional coordinates in space and thus a 3D mapping or model of the shape of the object at any point in time.

US 2009/066929 A1 describes establishing of the correspondence of the points for creation of a range image with stereo cameras. The scene is illuminated twice; thereof at least once with a random or pseudo random pattern. For both cameras, an image is taken for each of the illuminations and the quotient of brightnesses is calculated pixelwise. The correspondence is established on the basis of a comparison of the quotient of pixels on epipolar lines of different cameras. The illumination pattern is preferably highly modulated along the epipolar line; transversally or diagonally to it, it is not or only slightly modulated. For illumination, a projection unit is used which in a preferred arrangement comprises two superposed grating patterns which have a distance to each other, with at least one varying in a pseudo random manner, and with two closely neighboring light sources which shine through the gratings and thereby generate different pseudo random patterns, especially moiré patterns.

Despite the advantages implied by the above-mentioned devices and detectors, several technical challenges remain. Thus, the evaluation algorithms used require high computation power which is a severe cost driver. Furthermore, due to energy consumption and heat production of

the required computational resources, the computational demand limits use of such 3D sensor methods in outdoor and mobile applications.

Problem addressed by the invention

5

It is therefore an object of the present invention to provide devices and methods facing the above-mentioned technical challenges of known devices and methods. Specifically, it is an object of the present invention to provide devices and methods which reliably may determine a position of an object in space, preferably with a low technical effort and with low requirements in terms of technical resources and cost.

10

Summary of the invention

15

This problem is solved by the invention with the features of the independent patent claims. Advantageous developments of the invention, which can be realized individually or in combination, are presented in the dependent claims and/or in the following specification and detailed embodiments.

20

As used in the following, the terms "have", "comprise" or "include" or any arbitrary grammatical variations thereof are used in a non-exclusive way. Thus, these terms may both refer to a situation in which, besides the feature introduced by these terms, no further features are present in the entity described in this context and to a situation in which one or more further features are present. As an example, the expressions "A has B", "A comprises B" and "A includes B" may both refer to a situation in which, besides B, no other element is present in A (i.e. a situation in which A solely and exclusively consists of B) and to a situation in which, besides B, one or more further elements are present in entity A, such as element C, elements C and D or even further elements.

25

Further, it shall be noted that the terms "at least one", "one or more" or similar expressions indicating that a feature or element may be present once or more than once typically will be used only once when introducing the respective feature or element. In the following, in most cases, when referring to the respective feature or element, the expressions "at least one" or "one or more" will not be repeated, notwithstanding the fact that the respective feature or element may be present once or more than once.

35

Further, as used in the following, the terms "preferably", "more preferably", "particularly", "more particularly", "specifically", "more specifically" or similar terms are used in conjunction with optional features, without restricting alternative possibilities. Thus, features introduced by these terms are optional features and are not intended to restrict the scope of the claims in any way.

40

The invention may, as the skilled person will recognize, be performed by using alternative features. Similarly, features introduced by "in an embodiment of the invention" or similar expressions are intended to be optional features, without any restriction regarding alternative embodiments of the invention, without any restrictions regarding the scope of the invention and without

any restriction regarding the possibility of combining the features introduced in such a way with other optional or non-optional features of the invention.

In a first aspect of the present invention a detector for determining a position of at least one object is disclosed. As used herein, the term "object" refers to a point or region emitting at least one light beam. The light beam may originate from the object, such as by the object and/or at least one illumination source integrated or attached to the object emitting the light beam, or may originate from a different illumination source, such as from an illumination source directly or indirectly illuminating the object, wherein the light beam is reflected or scattered by the object. As used herein, the term "position" refers to at least one item of information regarding a location and/or orientation of the object and/or at least one part of the object in space. Thus, the at least one item of information may imply at least one distance between at least one point of the object and the at least one detector. As will be outlined in further detail below, the distance may be a longitudinal coordinate or may contribute to determining a longitudinal coordinate of the point of the object. Additionally or alternatively, one or more other items of information regarding the location and/or orientation of the object and/or at least one part of the object may be determined. As an example, additionally, at least one transversal coordinate of the object and/or at least one part of the object may be determined. Thus, the position of the object may imply at least one longitudinal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one transversal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one orientation information of the object, indicating an orientation of the object in space.

The detector comprises:

- at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by a reflection light beam propagating from the object to the detector, wherein the sensor element is adapted to determine at least one reflection image;
- at least one evaluation device, wherein the evaluation device is adapted to select at least one reflection feature of the reflection image, wherein the evaluation device is configured for determining at least one longitudinal region of the selected reflection feature of the reflection image by evaluating a combined signal Q from the sensor signals, wherein the evaluation device is adapted to determine at least one displacement region in at least one reference image corresponding to the longitudinal region, wherein the evaluation device is adapted to match the selected reflection feature with at least one reference feature within the displacement region.

As used herein, the term "sensor element" generally refers to a device or a combination of a plurality of devices configured for sensing at least one parameter. In the present case, the parameter specifically may be an optical parameter, and the sensor element specifically may be an optical sensor element. The sensor element may be formed as a unitary, single device or as

a combination of several devices. As further used herein, the term "matrix" generally refers to an arrangement of a plurality of elements in a predetermined geometrical order. The matrix, as will be outlined in further detail below, specifically may be or may comprise a rectangular matrix having one or more rows and one or more columns. The rows and columns specifically may be arranged in a rectangular fashion. It shall be outlined, however, that other arrangements are feasible, such as nonrectangular arrangements. As an example, circular arrangements are also feasible, wherein the elements are arranged in concentric circles or ellipses about a center point. For example, the matrix may be a single row of pixels. Other arrangements are feasible.

10 The optical sensors of the matrix specifically may be equal in one or more of size, sensitivity and other optical, electrical and mechanical properties. The light-sensitive areas of all optical sensors of the matrix specifically may be located in a common plane, the common plane preferably facing the object, such that a light beam propagating from the object to the detector may generate a light spot on the common plane.

15 As used herein, an "optical sensor" generally refers to a light-sensitive device for detecting a light beam, such as for detecting an illumination and/or a light spot generated by at least one light beam. As further used herein, a "light-sensitive area" generally refers to an area of the optical sensor which may be illuminated externally, by the at least one light beam, in response to which illumination the at least one sensor signal is generated. The light-sensitive area may specifically be located on a surface of the respective optical sensor. Other embodiments, however, are feasible. As used herein, the term "the optical sensors each having at least one light sensitive area" refers to configurations with a plurality of single optical sensors each having one light sensitive area and to configurations with one combined optical sensor having a plurality of light sensitive areas. Thus, the term "optical sensor" furthermore refers to a light-sensitive device configured to generate one output signal, whereas, herein, a light-sensitive device configured to generate two or more output signals, for example at least one CCD and/or CMOS device, is referred to as two or more optical sensors. As will further be outlined in detail below, each optical sensor may be embodied such that precisely one light-sensitive area is present in the respective optical sensor, such as by providing precisely one light-sensitive area which may be illuminated, in response to which illumination precisely one uniform sensor signal is created for the whole optical sensor. Thus, each optical sensor may be a single area optical sensor. The use of the single area optical sensors, however, renders the setup of the detector specifically simple and efficient. Thus, as an example, commercially available photo-sensors, such as commercially available silicon photodiodes, each having precisely one sensitive area, may be used in the set-up. Other embodiments, however, are feasible. Thus, as an example, an optical device comprising two, three, four or more than four light-sensitive areas may be used which is regarded as two, three, four or more than four optical sensors in the context of the present invention. As outlined above, the sensor element comprises a matrix of optical sensors. Thus, as an example, the optical sensors may be part of or constitute a pixelated optical device. As an example, the optical sensors may be part of or constitute at least one CCD and/or CMOS device having a matrix of pixels, each pixel forming a light-sensitive area.

As outlined above, the optical sensors specifically may be or may comprise photodetectors, preferably inorganic photodetectors, more preferably inorganic semiconductor photodetectors, most preferably silicon photodetectors. Specifically, the optical sensors may be sensitive in the infrared spectral range. All of the optical sensors of the matrix or at least a group of the optical sensors of the matrix specifically may be identical. Groups of identical optical sensors of the matrix specifically may be provided for different spectral ranges, or all optical sensors may be identical in terms of spectral sensitivity. Further, the optical sensors may be identical in size and/or with regard to their electronic or optoelectronic properties.

- Specifically, the optical sensors may be or may comprise inorganic photodiodes which are sensitive in the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers. Specifically, the optical sensors may be sensitive in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm. Infrared optical sensors which may be used for optical sensors may be commercially available infrared optical sensors, such as infrared optical sensors commercially available from Hamamatsu Photonics Deutschland GmbH, D-82211 Herrsching am Ammersee, Germany. Thus, as an example, the optical sensors may comprise at least one optical sensor of an intrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge photodiode, an InGaAs photodiode, an extended InGaAs photodiode, an InAs photodiode, an InSb photodiode, a HgCdTe photodiode. Additionally or alternatively, the optical sensors may comprise at least one optical sensor of an extrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge:Au photodiode, a Ge:Hg photodiode, a Ge:Cu photodiode, a Ge:Zn photodiode, a Si:Ga photodiode, a Si:As photodiode. Additionally or alternatively, the optical sensors may comprise at least one bolometer, preferably a bolometer selected from the group consisting of a VO bolometer and an amorphous Si bolometer.

- The matrix may be composed of independent optical sensors. Thus, a matrix of inorganic photodiodes may be composed. Alternatively, however, a commercially available matrix may be used, such as one or more of a CCD detector, such as a CCD detector chip, and/or a CMOS detector, such as a CMOS detector chip.

- Thus, generally, the optical sensors of the detector may form a sensor array or may be part of a sensor array, such as the above-mentioned matrix. Thus, as an example, the detector may comprise an array of optical sensors, such as a rectangular array, having m rows and n columns, with m , n , independently, being positive integers. Preferably, more than one column and more than one row is given, i.e. $n > 1$, $m > 1$. Thus, as an example, n may be 2 to 16 or higher and m may be 2 to 16 or higher. Preferably, the ratio of the number of rows and the number of columns is close to 1. As an example, n and m may be selected such that $0.3 \leq m/n \leq 3$, such as by choosing $m/n = 1:1$, $4:3$, $16:9$ or similar. As an example, the array may be a square array, having an equal number of rows and columns, such as by choosing $m=2$, $n=2$ or $m=3$, $n=3$ or the like.

The matrix specifically may be a rectangular matrix having at least one row, preferably a plurality of rows, and a plurality of columns. As an example, the rows and columns may be oriented essentially perpendicular, wherein, with respect to the term "essentially perpendicular", reference may be made to the definition given above. Thus, as an example, tolerances of less than 20°, specifically less than 10° or even less than 5°, may be acceptable. In order to provide a wide range of view, the matrix specifically may have at least 10 rows, preferably at least 50 rows, more preferably at least 100 rows. Similarly, the matrix may have at least 10 columns, preferably at least 50 columns, more preferably at least 100 columns. The matrix may comprise at least 50 optical sensors, preferably at least 100 optical sensors, more preferably at least 500 optical sensors. The matrix may comprise a number of pixels in a multi-mega pixel range. Other embodiments, however, are feasible. Thus, in setups in which an axial rotational symmetry is to be expected, circular arrangements or concentric arrangements of the optical sensors of the matrix, which may also be referred to as pixels, may be preferred.

Preferably, the sensor element may be oriented essentially perpendicular to an optical axis of the detector. Again, with respect to the term "essentially perpendicular", reference may be made to the definition and the tolerances given above. The optical axis may be a straight optical axis or may be bent or even split, such as by using one or more deflection elements and/or by using one or more beam splitters, wherein the essentially perpendicular orientation, in the latter cases, may refer to the local optical axis in the respective branch or beam path of the optical setup.

The reflection light beam may propagate from the object towards the detector. As will be outlined in further detail below, the reflection light beam may originate from the object or may originate from an illumination source, such as from an illumination source directly or indirectly illuminating the object, wherein the light beam is reflected or scattered by the object and, thereby, is at least partially directed towards the detector. The detector may be used in active and/or passive illumination scenarios. For example, the at least one illumination source may be adapted to illuminate the object, for example, by directing a light beam towards the object, which reflects the light beam. The illumination source may be or may comprise at least one multiple beam light source. For example, the illumination source may comprise at least one laser source and one or more diffractive optical elements (DOEs). Additionally or alternatively, the detector may use radiation already present in the scene such as from at least one ambient light source.

The reflection light beam specifically may fully illuminate the at least one optical sensor from which the center signal is generated, such that the at least one optical sensor from which the center signal arises is fully located within the light beam, with a width of the light beam being larger than the light-sensitive area of the at least one optical sensor from which the sensor signal arises. Contrarily, preferably, the reflection light beam specifically may create a light spot on the entire matrix which is smaller than the matrix, such that the light spot is fully located within the matrix. This situation may easily be adjusted by a person skilled in the art of optics by choosing one or more appropriate lenses or elements having a focusing or defocusing effect on the light beam, such as by using an appropriate transfer device as will be outlined in further de-

tail below. As further used herein, a “light spot” generally refers to a visible or detectable round or non-round illumination of an article, an area or object by a light beam.

As further used herein, a “sensor signal” generally refers to a signal generated by an optical sensor in response to the illumination by the light beam. Specifically, the sensor signal may be or may comprise at least one electrical signal, such as at least one analogue electrical signal and/or at least one digital electrical signal. More specifically, the sensor signal may be or may comprise at least one voltage signal and/or at least one current signal. More specifically, the sensor signal may comprise at least one photocurrent. Further, either raw sensor signals may be used, or the detector, the optical sensor or any other element may be adapted to process or preprocess the sensor signal, thereby generating secondary sensor signals, which may also be used as sensor signals, such as preprocessing by filtering or the like.

The light-sensitive areas specifically may be oriented towards the object. As used herein, the term “is oriented towards the object” generally refers to the situation that the respective surfaces of the light-sensitive areas are fully or partially visible from the object. Specifically, at least one interconnecting line between at least one point of the object and at least one point of the respective light-sensitive area may form an angle with a surface element of the light-sensitive area which is different from 0° , such as an angle in the range of 20° to 90° , preferably 80° to 90° such as 90° . Thus, when the object is located on the optical axis or close to the optical axis, the light beam propagating from the object towards the detector may be essentially parallel to the optical axis. As used herein, the term “essentially perpendicular” refers to the condition of a perpendicular orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less. Similarly, the term “essentially parallel” refers to the condition of a parallel orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less.

As used herein, the term “ray” generally refers to a line that is perpendicular to wavefronts of light which points in a direction of energy flow. As used herein, the term “beam” generally refers to a collection of rays. In the following, the terms “ray” and “beam” will be used as synonyms. As further used herein, the term “light beam” generally refers to an amount of light, specifically an amount of light traveling essentially in the same direction, including the possibility of the light beam having a spreading angle or widening angle. The light beam may have a spatial extension. Specifically, the light beam may have a non-Gaussian beam profile. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile. The trapezoid beam profile may have a plateau region and at least one edge region. The light beam specifically may be a Gaussian light beam or a linear combination of Gaussian light beams, as will be outlined in further detail below. Other embodiments are feasible, however. The transfer device may be configured for one or more of adjusting, defining and determining the beam profile, in particular a shape of the beam profile.

The optical sensors may be sensitive in one or more of the ultraviolet, the visible or the infrared spectral range. Specifically, the optical sensors may be sensitive in the visible spectral range

from 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm. Specifically, the optical sensors may be sensitive in the near infrared region. Specifically, the optical sensors may be sensitive in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm. The optical sensors, specifically, may
5 be sensitive in the infrared spectral range, specifically in the range of 780 nm to 3.0 micrometers. For example, the optical sensors each, independently, may be or may comprise at least one element selected from the group consisting of a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. For example, the optical sensors may be or may comprise at least one element selected from the group consisting of a CCD sensor element, a
10 CMOS sensor element, a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. Any other type of photosensitive element may be used. As will be outlined in further detail below, the photosensitive element generally may fully or partially be made of inorganic materials and/or may fully or partially be made of organic materials. Most commonly, as will be outlined in further detail below, one or more photodiodes may be used, such as com-
15 mercially available photodiodes, e.g. inorganic semiconductor photodiodes.

The detector may be adapted to determine at least one distance information of the object by using triangulation and/or structured light techniques. In known 3D sensing devices, such as
20 devices using triangulation or structured light techniques, due to correspondence problems regular, constant or periodic pattern are not suitable since each measured point has to be assigned to one reference point of a reference pattern.

As used herein, the term "reflection image" refers to an image determined by the optical sensor comprising at least one reflection feature. As used herein, the term "reflection feature" refers to
25 a feature in an image plane generated by the object in response to illumination, for example with at least one illumination feature. The reflection image may comprise the at least one reflection pattern comprising the at least one reflection feature. As used herein, the term "illumination feature" refers to at least one arbitrary shaped feature generated by at least one ambient light source or at least one illumination source adapted to illuminate the object. As used herein, the
30 term "determining at least one reflection image" refers to one or more of imaging, recording and generating of the reflection image. As used herein, the term "select at least one reflection feature" refers to one or more of identifying, determining and choosing at least one reflection feature of the reflection image. The detector may be adapted to determine the longitudinal coordinate of an object point for at least one reflection feature of the reflection image from the com-
35 bined signal. Thus, the detector may be adapted to pre-classify the at least one reflection feature of the reflection image. This allows using illumination patterns comprising regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that hexagonal patterns may be preferred.

40 The evaluation device may be adapted to perform at least one image analysis and/or image processing in order to identify the reflection feature. The image analysis and/or image processing may use at least one feature detection algorithm. The image analysis and/or image

processing may comprise one or more of the following: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency decomposition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be determined manually by a user or may be determined automatically, such as by recognizing an object within an image generated by the optical sensors.

The evaluation device is configured for determining at least one longitudinal region of the selected reflection feature of the reflection image by evaluating a combined signal Q from the sensor signals. The evaluation device may be adapted to determine at least one longitudinal coordinate z of the selected reflection feature by evaluating the combined signal Q, wherein the longitudinal region is given by the longitudinal coordinate z and an error interval $\pm \varepsilon$. As used herein, the term "longitudinal region" refers to at least one uncertainty interval defined by the longitudinal coordinate z and the measurement uncertainty $\pm \varepsilon$ of the determination of the longitudinal coordinate from the combined signal Q. Error ε may depend on measurement uncertainty of the optical sensor. The measurement uncertainty of the optical sensors may be pre-determined and/or estimated and/or may be deposited in at least one data storage unit of the evaluation device. For example, the error interval may be $\pm 10\%$, preferably $\pm 5\%$, more preferably $\pm 1\%$. As used herein, the term "combined signal Q" refers to a signal which is generated by combining the sensor signals, in particular by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals. The evaluation device may be configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals. The evaluation device may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal region for determining the longitudinal region. For example, the evaluation device may be configured for deriving the combined

$$\text{signal Q by } Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy},$$

wherein x and y are transversal coordinates, A1 and A2 are different areas of at least one beam profile of the reflection light beam at the sensor position, and $E(x, y, z_o)$ denotes the beam profile given at the object distance z_o . Area A1 and area A2 may differ. In particular, A1 and A2 are not congruent. Thus, A1 and A2 may differ in one or more of the shape or content. As used herein, the term "beam profile" relates to a spatial distribution, in particular in at least one plane per-

pendicular to the propagation of the light beam, of an intensity of the light beam. The beam profile may be a transverse intensity profile of the light beam. The beam profile may be a cross section of the light beam. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles. Generally the beam profile is dependent on luminance $L(z_0)$ and beam shape $S(x,y;z_0)$, $E(x,y;z_0)=L \cdot S$. Thus, by deriving the combined signal it may allow determining the longitudinal coordinate independent from luminance. In addition, using the combined signal allows determination of the distance z_0 independent from the object size. Thus, the combined signal allows determination of the distance z_0 independent from the material properties and/or reflective properties and/or scattering properties of the object and independent from alterations of the light source such as by manufacturing precision, heat, water, dirt, damages on the lens, or the like.

Each of the sensor signals may comprise at least one information of at least one area of the beam profile of the light beam. As used herein, the term "area of the beam profile" generally refers to an arbitrary region of the beam profile at the sensor position used for determining the combined signal Q . The light-sensitive areas may be arranged such that a first sensor signal comprises information of a first area of the beam profile and a second sensor signal comprises information of a second area of the beam profile. The first area of the beam profile and second area of the beam profile may be one or both of adjacent or overlapping regions. The first area of the beam profile and the second area of the beam profile may be not congruent in area.

The evaluation device may be configured to determine and/or to select the first area of the beam profile and the second area of the beam profile. The first area of the beam profile may comprise essentially edge information of the beam profile and the second area of the beam profile may comprise essentially center information of the beam profile. The beam profile may have a center, i.e. a maximum value of the beam profile and/or a center point of a plateau of the beam profile and/or a geometrical center of the light spot, and falling edges extending from the center. The second region may comprise inner regions of the cross section and the first region may comprise outer regions of the cross section. As used herein, the term "essentially center information" generally refers to a low proportion of edge information, i.e. proportion of the intensity distribution corresponding to edges, compared to a proportion of the center information, i.e. proportion of the intensity distribution corresponding to the center. Preferably the center information has a proportion of edge information of less than 10%, more preferably of less than 5%, most preferably the center information comprises no edge content. As used herein, the term "essentially edge information" generally refers to a low proportion of center information compared to a proportion of the edge information. The edge information may comprise information of the whole beam profile, in particular from center and edge regions. The edge information may have a proportion of center information of less than 10%, preferably of less than 5%, more preferably the edge information comprises no center content. At least one area of the beam profile may be determined and/or selected as second area of the beam profile if it is close or around the center and comprises essentially center information. At least one area of the beam profile may be determined and/or selected as first area of the beam profile if it comprises at least parts

of the falling edges of the cross section. For example, the whole area of the cross section may be determined as first region. The first area of the beam profile may be area A2 and the second area of the beam profile may be area A1.

- 5 Other selections of the first area A1 and second area A2 may be feasible. For example, the first area may comprise essentially outer regions of the beam profile and the second area may comprise essentially inner regions of the beam profile. For example, in case of a two-dimensional beam profile, the beam profile may be divided in a left part and a right part, wherein the first area may comprise essentially areas of the left part of the beam profile and the second area
10 may comprise essentially areas of the right part of the beam profile.

The edge information may comprise information relating to a number of photons in the first area of the beam profile and the center information may comprise information relating to a number of photons in the second area of the beam profile. The evaluation device may be adapted for determining an area integral of the beam profile. The evaluation device may be adapted to determine the edge information by integrating and/or summing of the first area. The evaluation device may be adapted to determine the center information by integrating and/or summing of the second area. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid. Further, when trapezoid beam
15 profiles may be assumed, the determination of edge and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

- 25 Additionally or alternatively, the evaluation device may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized, for example, by replacing the area integrals in the combined signal Q by a line integral along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or
30 cuts may result in improved distance information.

In one embodiment, the light beam propagating from the object to the detector may illuminate the sensor element with at least one pattern comprising at least one feature point. As used herein, the term "feature point" refers to at least one at least partially extended feature of the pattern. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors. The
35 central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

For example, the light beam propagating from the object to the detector may illuminate the optical sensors with at least one line pattern. The line pattern may be generated by the object, for example in response to an illumination by the at least one illumination source with an illumination pattern comprising the at least one line pattern. A1 may correspond to an area with a full line width of the line pattern on the optical sensors, in particular on the light sensitive area of the optical sensors. The line pattern on the optical sensors may be widened and/or displaced compared to the line pattern of the illumination pattern such that the line width on the optical sensors is increased. In particular, in case of a matrix of optical sensors, the line width of the line pattern on the optical sensors may change from one column to another column. A2 may be a central area of the line pattern on the optical sensors. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern may be segmented on the optical sensors. Each column of the matrix of optical sensors may comprise center information of intensity in the central area of the line pattern and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern.

For example, the light beam propagating from the object to the detector may illuminate the sensor element with at least one point pattern. The point pattern may be generated by the object, for example in response to an illumination by the at least one light source with an illumination pattern comprising the at least one point pattern. A1 may correspond to an area with a full radius of a point of the point pattern on the optical sensors. A2 may be a central area of the point in the point pattern on the optical sensors. The central area may be a constant value. The central area may have a radius compared to the full radius. For example, the central area may have a radius from 0.1 to 0.9 of the full radius, preferably from 0.4 to 0.6 of the full radius.

The light beam propagating from the object to the detector may illuminate the sensor element with a reflection pattern comprising both point patterns and line patterns. Other embodiments in addition or alternatively to line pattern and point pattern are feasible.

The evaluation device may be configured to derive the combined signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information. Thus, essentially, photon ratios may be used as the physical basis of the method.

For example, the evaluation device may be configured for evaluating the sensor signals, by

- a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
- b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;

- c) determining at least one combined signal by combining the center signal and the sum signal; and
- d) determining the at least one longitudinal coordinate z of the selected feature by evaluating the combined signal.

5

As explained, e.g. in WO 2012/110924 A1 or WO 2014/097181 A1, typically, a predetermined or determinable relationship exists between a size of a light spot, such as a diameter of the light spot, a beam waist or an equivalent diameter, and the longitudinal coordinate of the object from which the light beam propagates towards the detector. Without wishing to be bound by this theory, the light spot may be characterized by two measurement variables: a measurement signal measured in a small measurement patch in the center or close to the center of the light spot, also referred to as the center signal, and an integral or sum signal integrated over the light spot, with or without the center signal. For a light beam having a certain total power which does not change when the beam is widened or focused, the sum signal should be independent from the spot size of the light spot, and, thus, should, at least when linear optical sensors within their respective measurement range are used, be independent from the distance between the object and the detector. The center signal, however, is dependent on the spot size. Thus, the center signal typically increases when the light beam is focused, and decreases when the light beam is defocused. By comparing the center signal and the sum signal, thus, an item of information on the size of the light spot generated by the light beam and, thus, on the longitudinal coordinate of the object may be generated. The comparing of the center signal and the sum signal, as an example, may be done by forming the combined signal Q out of the center signal and the sum signal and by using a predetermined or determinable relationship between the longitudinal coordinate and the quotient signal for deriving the longitudinal coordinate.

25

The use of a matrix of optical sensors provides a plurality of advantages and benefits. Thus, the center of the light spot generated by the light beam on the sensor element, such as on the common plane of the light-sensitive areas of the optical sensors of the matrix of the sensor element, may vary with a transversal position of the object. By using a matrix of optical sensors, the detector according to the present invention may adapt to these changes in conditions and, thus, may determine the center of the light spot simply by comparing the sensor signals. Consequently, the detector according to the present invention may, by itself, choose the center signal and determine the sum signal and, from these two signals, derive a combined signal which contains information on the longitudinal coordinate of the object. By evaluating the combined signal, the longitudinal coordinate of the object may, thus, be determined. The use of the matrix of optical sensors, thus, provides a significant flexibility in terms of the position of the object, specifically in terms of a transversal position of the object.

35

The transversal position of the light spot on the matrix of optical sensors, such as the transversal position of the at least one optical sensor generating the sensor signal, may even be used as an additional item of information, from which at least one item of information on a transversal position of the object may be derived, as e.g. disclosed in WO 2014/198629 A1. Additionally or alternatively, as will be outlined in further detail below, the detector according to the present

40

invention may contain at least one additional transversal detector for, in addition to the at least one longitudinal coordinate, detecting at least one transversal coordinate of the object.

Consequently, in accordance with the present invention, the term "center signal" generally refers to the at least one sensor signal comprising essentially center information of the beam profile. For example, the center signal may be the signal of the at least one optical sensor having the highest sensor signal out of the plurality of sensor signals generated by the optical sensors of the entire matrix or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable within an image generated by the optical sensors of the matrix. As used herein, the term "highest sensor signal" refers to one or both of a local maximum or a maximum in a region of interest. The center signal may arise from a single optical sensor or, as will be outlined in further detail below, from a group of optical sensors, wherein, in the latter case, as an example, the sensor signals of the group of optical sensors may be added up, integrated or averaged, in order to determine the center signal. The group of optical sensors from which the center signal arises may be a group of neighboring optical sensors, such as optical sensors having less than a predetermined distance from the actual optical sensor having the highest sensor signal, or may be a group of optical sensors generating sensor signals being within a predetermined range from the highest sensor signal. The group of optical sensors from which the center signal arises may be chosen as large as possible in order to allow maximum dynamic range. The evaluation device may be adapted to determine the center signal by integration of the plurality of sensor signals, for example the plurality of optical sensors around the optical sensor having the highest sensor signal. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid, in particular of a plateau of the trapezoid.

As outlined above, the center signal generally may be a single sensor signal, such as a sensor signal from the optical sensor in the center of the light spot, or may be a combination of a plurality of sensor signals, such as a combination of sensor signals arising from optical sensors in the center of the light spot, or a secondary sensor signal derived by processing a sensor signal derived by one or more of the aforementioned possibilities. The determination of the center signal may be performed electronically, since a comparison of sensor signals is fairly simply implemented by conventional electronics, or may be performed fully or partially by software. Specifically, the center signal may be selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; an in-

tegral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

- 5 Similarly, the term "sum signal" generally refers to a signal comprising essentially edge information of the beam profile. For example, the sum signal may be derived by adding up the sensor signals, integrating over the sensor signals or averaging over the sensor signals of the entire matrix or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable within an image generated by the optical sensors of the matrix.
- 10 When adding up, integrating over or averaging over the sensor signals, the actual optical sensors from which the sensor signal is generated may be left out of the adding, integration or averaging or, alternatively, may be included into the adding, integration or averaging. The evaluation device may be adapted to determine the sum signal by integrating signals of the entire matrix, or of the region of interest within the matrix. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the entire trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of
- 15 edge and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.
- 20

Similarly, the center signal and edge signal may also be determined by using segments of the beam profile such as circular segments of the beam profile. For example, the beam profile may be divided into two segments by a secant or a chord that does not pass the center of the beam profile. Thus, one segment will essentially contain edge information, while the other segment

25 will contain essentially center information. For example, to further reduce the amount of edge information in the center signal, the edge signal may further be subtracted from the center signal.

- 30 Additionally or alternatively, the evaluation device may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized for example by replacing the area integrals in the combined signal Q by a line integral along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or
- 35 cuts may result in an improved distance information.

The combined signal may be a signal which is generated by combining the center signal and the sum signal. Specifically, the combination may include one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa. Additionally or alternatively, the combined signal may comprise an arbitrary signal or signal combination which

40

contains at least one item of information on a comparison between the center signal and the sum signal.

The evaluation device may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between the sensor signals. In particular, the evaluation device is configured to determine the at least one coordinate z of the object by using at least one known, determinable or predetermined relationship between a quotient signal derived from the sensor signals and the longitudinal coordinate.

Raw sensor signals of the optical sensors may be used for evaluation or secondary sensor signals derived thereof. As used herein, the term "secondary sensor signal" generally refers to a signal, such as an electronic signal, more preferably an analogue and/or a digital signal, which is obtained by processing one or more raw signals, such as by filtering, averaging, demodulating or the like. Thus, image processing algorithms may be used for generating secondary sensor signals from the totality of sensor signals of the matrix or from a region of interest within the matrix. Specifically, the detector, such as the evaluation device, may be configured for transforming the sensor signals of the optical sensor, thereby generating secondary optical sensor signals, wherein the evaluation device is configured for performing steps a)-d) by using the secondary optical sensor signals. The transformation of the sensor signals specifically may comprise at least one transformation selected from the group consisting of: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency decomposition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be determined manually by a user or may be determined automatically, such as by recognizing an object within an image generated by the optical sensors. As an example, a vehicle, a person or another type of predetermined object may be determined by automatic image recognition within an image, i.e. within the totality of sensor signals generated by the optical sensors, and the region of interest may be chosen such that the object is located within the region of interest. In this case, the evaluation, such as the determination of the longitudinal coordinate, may be performed for the region of interest, only. Other implementations, however, are feasible.

As outlined above, the detection of the center of the light spot, i.e. the detection of the center signal and/or of the at least one optical sensor from which the center signal arises, may be per-

formed fully or partially electronically or fully or partially by using one or more software algorithms. Specifically, the evaluation device may comprise at least one center detector for detecting the at least one highest sensor signal and/or for forming the center signal. The center detector specifically may fully or partially be embodied in software and/or may fully or partially be embodied in hardware. The center detector may fully or partially be integrated into the at least one sensor element and/or may fully or partially be embodied independently from the sensor element.

As outlined above, the sum signal may be derived from all sensor signals of the matrix, from the sensor signals within a region of interest or from one of these possibilities with the sensor signals arising from the optical sensors contributing to the center signal excluded. In every case, a reliable sum signal may be generated which may be compared with the center signal reliably, in order to determine the longitudinal coordinate. Generally, the sum signal may be selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; an integral of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal. Other options, however, exist.

The summing may be performed fully or partially in software and/or may be performed fully or partially in hardware. A summing is generally possible by purely electronic means which, typically, may easily be implemented into the detector. Thus, in the art of electronics, summing devices are generally known for summing two or more electrical signals, both analogue signals and digital signals. Thus, the evaluation device may comprise at least one summing device for forming the sum signal. The summing device may fully or partially be integrated into the sensor element or may fully or partially be embodied independently from the sensor element. The summing device may fully or partially be embodied in one or both of hardware or software.

As outlined above, the comparison between the center signal and the sum signal specifically may be performed by forming one or more quotient signals. Thus, generally, the combined signal may be a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of the center signal and a linear combination of the sum signal and the center signal or vice versa; forming a

quotient of the sum signal and a linear combination of the sum signal and the center signal or vice versa; forming a quotient of an exponentiation of the center signal and an exponentiation of the sum signal or vice versa. Other options, however, exist. The evaluation device may be configured for forming the one or more quotient signals. The evaluation device may further be configured for determining the at least one longitudinal coordinate by evaluating the at least one quotient signal.

The evaluation device specifically may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal coordinate, in order to determine the at least one longitudinal coordinate. Thus, due to the reasons disclosed above and due to the dependency of the properties of the light spot on the longitudinal coordinate, the combined signal Q typically is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, a simple quotient of the sensor signal s_{center} and the sum signal s_{sum} $Q = s_{\text{center}}/s_{\text{sum}}$ may be a monotonously decreasing function of the distance. Without wishing to be bound by this theory, it is believed that this is due to the fact that, in the preferred setup described above, both the center signal s_{center} and the sum signal s_{sum} decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, the center signal s_{center} decreases more rapidly than the sum signal s_{sum} , since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. The quotient of the center signal and the sum signal, thus, continuously decreases with increasing diameter of the light beam or diameter of the light spot on the light-sensitive areas of the optical sensors of the matrix. The quotient, further, is typically independent from the total power of the light beam, since the total power of the light beam forms a factor both in the center signal and in the sum sensor signal. Consequently, the combined signal Q may form a secondary signal which provides a unique and unambiguous relationship between the center signal and the sum signal and the size or diameter of the light beam. Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship between the center signal and the sum signal on the one hand and the longitudinal coordinate on the other hand may exist. For the latter, reference e.g. may be made to one or more of the above-mentioned prior art documents, such as WO 2014/097181 A1. The predetermined relationship may be determined by analytical considerations, such as by assuming a linear combination of Gaussian light beams, by empirical measurements, such as measurements measuring the combined signal and/or the center signal and the sum signal or secondary signals derived thereof as a function of the longitudinal coordinate of the object, or both.

Thus, generally, the evaluation device may be configured for determining the longitudinal coordinate by evaluating the combined signal Q . This determining may be a one-step process, such as by directly combining the center signal and the sum signal and deriving the longitudinal coordinate thereof, or may be a multiple step process, such as by firstly deriving the combined sig-

nal from the center signal and the sum signal and, secondly, by deriving the longitudinal coordinate from the combined signal. Both options, i.e. the option of steps c) and d) being separate and independent steps and the option of steps c) and d) being fully or partially combined, shall be comprised by the present invention.

5

The evaluation device may be configured for using at least one predetermined relationship between the combined signal and the longitudinal coordinate. The predetermined relationship may be one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship. The evaluation device may comprise at least one data storage device for storing the predetermined relationship, such as a lookup list or a lookup table.

10

The combined signal Q may be determined by using various means. As an example, a software means for deriving the quotient signal, a hardware means for deriving the quotient signal, or both, may be used and may be implemented in the evaluation device. Thus, the evaluation device, as an example, may comprise at least one divider, wherein the divider is configured for deriving the quotient signal. The divider may fully or partially be embodied as one or both of a software divider or a hardware divider. The divider may fully or partially be integrated into the sensor element answers or may fully or partially be embodied independent from the sensor element.

15

20

The detector may comprise at least one optical element selected from the group consisting of: transfer device, such as at least one lens and/or at least one lens system, at least one diffractive optical element. The term "transfer device", also denoted as "transfer system", may generally refer to one or more optical elements which are adapted to modify the light beam, such as by modifying one or more of a beam parameter of the light beam, a width of the light beam or a direction of the light beam. The transfer device may be adapted to guide the light beam onto the optical sensors. The transfer device specifically may comprise one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system. As used herein, the term "focal length" of the transfer device refers to a distance over which incident collimated rays which may impinge the transfer device are brought into a "focus" which may also be denoted as "focal point". Thus, the focal length constitutes a measure of an ability of the transfer device to converge an impinging light beam. Thus, the transfer device may comprise one or more imaging elements which can have the effect of a converging lens. By way of example, the transfer device can have one or more lenses, in particular one or more refractive lenses, and/or one or more convex mirrors. In this example, the focal length may be defined as a distance from the center of the thin refractive lens to the principal focal points of the thin lens. For a converging thin refractive lens, such as a convex or biconvex thin lens, the focal length may be considered as being positive and may provide the distance at which a beam of collimated light impinging the thin lens as the transfer device may be focused into a single spot. Additionally, the transfer

25

30

35

40

device can comprise at least one wavelength-selective element, for example at least one optical filter. Additionally, the transfer device can be designed to impress a predefined beam profile on the electromagnetic radiation, for example, at the location of the sensor region and in particular the sensor area. The abovementioned optional embodiments of the transfer device can, in principle, be realized individually or in any desired combination.

The transfer device may have an optical axis. In particular, the detector and the transfer device have a common optical axis. As used herein, the term "optical axis of the transfer device" generally refers to an axis of mirror symmetry or rotational symmetry of the lens or lens system. The optical axis of the detector may be a line of symmetry of the optical setup of the detector. The detector comprises at least one transfer device, preferably at least one transfer system having at least one lens. The transfer system, as an example, may comprise at least one beam path, with the elements of the transfer system in the beam path being located in a rotationally symmetrical fashion with respect to the optical axis. Still, as will also be outlined in further detail below, one or more optical elements located within the beam path may also be off-centered or tilted with respect to the optical axis. In this case, however, the optical axis may be defined sequentially, such as by interconnecting the centers of the optical elements in the beam path, e.g. by interconnecting the centers of the lenses, wherein, in this context, the optical sensors are not counted as optical elements. The optical axis generally may denote the beam path. Therein, the detector may have a single beam path along which a light beam may travel from the object to the optical sensors, or may have a plurality of beam paths. As an example, a single beam path may be given or the beam path may be split into two or more partial beam paths. In the latter case, each partial beam path may have its own optical axis. The optical sensors may be located in one and the same beam path or partial beam path. Alternatively, however, the optical sensors may also be located in different partial beam paths.

The transfer device may constitute a coordinate system, wherein a longitudinal coordinate l is a coordinate along the optical axis and wherein d is a spatial offset from the optical axis. The coordinate system may be a polar coordinate system in which the optical axis of the transfer device forms a z -axis and in which a distance from the z -axis and a polar angle may be used as additional coordinates. A direction parallel or antiparallel to the z -axis may be considered a longitudinal direction, and a coordinate along the z -axis may be considered a longitudinal coordinate l . Any direction perpendicular to the z -axis may be considered a transversal direction, and the polar coordinate and/or the polar angle may be considered a transversal coordinate.

As further used herein, the term "evaluation device" generally refers to an arbitrary device adapted to perform the named operations, preferably by using at least one data processing device and, more preferably, by using at least one processor and/or at least one application-specific integrated circuit. Thus, as an example, the at least one evaluation device may comprise at least one data processing device having a software code stored thereon comprising a number of computer commands. The evaluation device may provide one or more hardware elements for performing one or more of the named operations and/or may provide one or more processors with software running thereon for performing one or more of the named operations.

The above-mentioned operations, including determining the at least one longitudinal coordinate of the object, are performed by the at least one evaluation device. Thus, as an example, one or more of the above-mentioned relationships may be implemented in software and/or hardware, such as by implementing one or more lookup tables. Thus, as an example, the evaluation device may comprise one or more programmable devices such as one or more computers, application-specific integrated circuits (ASICs), Digital Signal Processors (DSPs), or Field Programmable Gate Arrays (FPGAs) which are configured to perform the above-mentioned evaluation, in order to determine the at least one longitudinal coordinate of the object. Additionally or alternatively, however, the evaluation device may also fully or partially be embodied by hardware.

As outlined above, by evaluating the center signal and the sum signal, the detector may be enabled to determine the at least one longitudinal coordinate of the object, including the option of determining the longitudinal coordinate of the whole object or of one or more parts thereof. In addition, however, other coordinates of the object, including one or more transversal coordinates and/or rotational coordinates, may be determined by the detector, specifically by the evaluation device. Thus, as an example, one or more transversal sensors may be used for determining at least one transversal coordinate of the object. As outlined above, the position of the at least one optical sensor from which the center signal arises may provide information on the at least one transversal coordinate of the object, wherein, as an example, a simple lens equation may be used for optical transformation and for deriving the transversal coordinate. Additionally or alternatively, one or more additional transversal sensors may be used and may be comprised by the detector. Various transversal sensors are generally known in the art, such as the transversal sensors disclosed in WO 2014/097181 A1 and/or other position-sensitive devices (PSDs), such as quadrant diodes, CCD or CMOS chips or the like. Additionally or alternatively, as an example, the detector according to the present invention may comprise one or more PSDs disclosed in R.A. Street (Ed.): *Technology and Applications of Amorphous Silicon*, Springer-Verlag Heidelberg, 2010, pp. 346-349. Other embodiments are feasible. These devices may generally also be implemented into the detector according to the present invention. As an example, a part of the light beam may be split off within the detector, by at least one beam splitting element. The split-off portion, as an example, may be guided towards a transversal sensor, such as a CCD or CMOS chip or a camera sensor, and a transversal position of a light spot generated by the split-off portion on the transversal sensor may be determined, thereby determining at least one transversal coordinate of the object. Consequently, the detector according to the present invention may either be a one-dimensional detector, such as a simple distance measurement device, or may be embodied as a two-dimensional detector or even as a three-dimensional detector. Further, as outlined above or as outlined in further detail below, by scanning a scenery or an environment in a one-dimensional fashion, a three-dimensional image may also be created. Consequently, the detector according to the present invention specifically may be one of a one-dimensional detector, a two-dimensional detector or a three-dimensional detector. The evaluation device may further be configured to determine at least one transversal coordinate x , y of the object. The evaluation device may be adapted to combine the information

of the longitudinal coordinate and the transversal coordinate and to determine a position of the object in space.

As outlined above, the evaluation device is adapted to determine at least one displacement region in at least one reference image corresponding to the longitudinal region. As used herein, the term "reference image" refers to an image different from the reflection image which is determined at a different spatial position compared to the reflection image. The reference image may be determined by one or more of recording at least one reference feature, imaging the at least one reference feature, calculating of the reference image. The reference image and the reflection image may be images of the object determined at different spatial positions having a fixed distance. The distance may be a relative distance, also called baseline. The evaluation device may be adapted to determine the at least one reference feature in the at least one reference image corresponding to the at least one reflection feature. As outlined above, the evaluation device may be adapted to perform an image analysis and to identify features of the reflection image. The evaluation device may be adapted to identify at least one reference feature in the reference image having an essentially identical longitudinal coordinate as the selected reflection feature. The term "essentially identical" refers to identical within 10%, preferably 5%, most preferably 1%. The reference feature corresponding to the reflection feature may be determined using epipolar geometry. For description of epipolar geometry reference is made, for example, to chapter 2 in X. Jiang, H. Bunke: „Dreidimensionales Computersehen“ Springer, Berlin Heidelberg, 1997. Epipolar geometry may assume that the reference image and the reflection image may be images of the object determined at different spatial positions and/or spatial orientations having a fixed distance. The evaluation device may be adapted to determine an epipolar line in the reference image. Relative position of the reference image and reflection image may be known. For example, relative position of the reference image and reflection image may be stored within at least one storage unit of the evaluation device. The evaluation device may be adapted to determine a straight line extending from the selected reflection feature of the reflection image. The straight line may comprise possible object features corresponding to the selected feature. The straight line and the baseline span an epipolar plane. As the reference image is determined at a different relative position from the reflection image, the corresponding possible object features may be imaged on a straight line, called epipolar line, in the reference image. Thus, a feature of the reference image corresponding to the selected feature of the reflection image lies on the epipolar line. Due to distortions of the image or changes in the system parameters such as due to ageing, temperature changes, mechanical stress or the like, epipolar lines may intersect or be very close to each other and/or the correspondence between reference feature and reflection feature may be unclear. Further, each known position or object in the real world may be projected onto the reference image and vice versa. The projection may be known due to a calibration of the detector, whereas the calibration is comparable to a teaching of the epipolar geometry of the specific camera.

40

As used herein, the term "displacement region" refers to a region in the reference image in which the reference feature corresponding to the selected reflection feature may be imaged. Specifically, the displacement region may be a region in the reference image in which the refer-

ence feature corresponding to the selected reflection feature is expected to be located in the reference image. Depending on the distance to the object, an image position of the reference feature corresponding to the reflection feature may be displaced within the reference image compared to an image position of the reflection feature in the reflection image. The displacement region may comprise only one reference feature. The displacement region may also comprise more than one reference feature. The displacement region may comprise an epipolar line or a section of an epipolar line. The displacement region may comprise more than one epipolar line or more sections of more than one epipolar line. As used herein, the term "reference feature" refers to at least one feature of the reference image. The displacement region may extend along the epipolar line, orthogonal to an epipolar line, or both. The evaluation device may be adapted to determine the reference feature along the epipolar line corresponding to the longitudinal coordinate z and to determine an extent of the displacement region along the epipolar line corresponding to the error interval $\pm \varepsilon$ or orthogonal to an epipolar line. The measurement uncertainty of the distance measurement using the combined signal Q may result in a displacement region which is non-circular since the measurement uncertainty may be different for different directions. Specifically, the measurement uncertainty along the epipolar line or epipolar lines may be greater than the measurement uncertainty in an orthogonal direction with respect to the epipolar line or epipolar lines. The displacement region may comprise an extend in an orthogonal direction with respect to the epipolar line or epipolar lines. The evaluation device may determine a displacement region around the image position of the reflection feature. The evaluation device may be adapted to determine the longitudinal coordinate z for the reflection feature and an error interval $\pm \varepsilon$ from the combined signal Q to determine the displacement region along the epipolar line corresponding to $z \pm \varepsilon$. The evaluation device is adapted to match the selected reflection feature with at least one reference feature within the displacement region. As used herein, the term "matching" refers to determining and/or evaluating corresponding reference and reflection features. The evaluation device may be adapted to match the selected feature of the reflection image with the reference feature within the displacement region by using at least one evaluation algorithm considering the determined longitudinal coordinate z . The evaluation algorithm may be a linear scaling algorithm. The evaluation device may be adapted to determine the epipolar line closest to and/or within the displacement region. The evaluation device may be adapted to determine the epipolar line closest to the image position of the reflection feature. The extent of the displacement region along the epipolar line may be larger than the extent of the displacement region orthogonal to the epipolar line. The evaluation device may be adapted to determine an epipolar line before determining a corresponding reference feature. The evaluation device may determine a displacement region around the image position of each reflection feature. The evaluation device may be adapted to assign an epipolar line to each displacement region of each image position of the reflection features, such as by assigning the epipolar line closest to a displacement region and/or within a displacement region and/or closest to a displacement region along a direction orthogonal to the epipolar line. The evaluation device may be adapted to determine the reference feature corresponding to the image position of the reflection feature by determining the reference feature closest to the assigned displacement region and/or within the assigned displacement region and/or closest to the assigned displacement

region along the assigned epipolar line and/or within the assigned displacement region along the assigned epipolar line.

Additionally or alternatively, the evaluation device may be configured to perform the following steps:

- 5 - Determining the displacement region for the image position of each reflection feature;
- Assigning an epipolar line to the displacement region of each reflection feature such as by assigning the epipolar line closest to a displacement region and/or within a displacement region and/or closest to a displacement region along a direction orthogonal to the epipolar line;
- 10 - Assigning and/or determining at least one reference feature to each reflection feature such as by assigning the reference feature closest to the assigned displacement region and/or within the assigned displacement region and/or closest to the assigned displacement region along the assigned epipolar line and/or within the assigned displacement region along the assigned epipolar line.

- 15 Additionally or alternatively, the evaluation device may be adapted to decide between more than one epipolar line and/or reference feature to be assigned to a reflection feature such as by comparing distances of reflection features and/or epipolar lines within the reference image and/or by comparing error weighted distances, such as ϵ -weighted distances of reflection features and/or epipolar lines within the reference image and assigning the epipolar line and/or
- 20 reference feature in shorter distance and/or ϵ -weighted distance to the reference feature and/or reflection feature.

- Preferably, the detector may be adapted to pre-classify the selected reflection feature using the combined signal Q such that an unambiguous assignment to one reference feature is possible. In particular, illumination features of the illumination pattern may be arranged such that corresponding reference features of the reference image may have a relative distance to each other as large as possible on the epipolar line. The illumination features of the illumination pattern may be arranged such that only few reference features are positioned on the epipolar line. For example, the illumination pattern may comprise at least one hexagonal pattern. Preferably, the illumination pattern may comprise at least one hexagonal pattern, wherein the pattern is rotated relative to the baseline. Preferably, the illumination pattern may comprise at least one displaced hexagonal pattern, wherein individual points of the hexagonal pattern are displaced by a random distance from the regular position, for example orthogonal to the epipolar line of the point.
- 30 The displacement of the individual points may be smaller than half of the distance between two parallel epipolar lines, preferably smaller than one fourth of the distance between two parallel epipolar lines. The displacement of the individual points may be as such that two points are not displaced above each other.

- 40 The evaluation device may be adapted to determine a displacement of the matched reference feature and the selected reflection feature. As used herein, the term "displacement" refers to difference between a position in the reference image to a position in the reflection image. The evaluation device may be adapted to determine a longitudinal information of the matched fea-

ture using a predetermined relationship between a longitudinal coordinate and the displacement. As used herein, the term "longitudinal information" refers to information relating to the longitudinal coordinate. For example, the longitudinal information may be a distance value. The evaluation device may be adapted to determine the pre-determined relationship by using triangulation methods. In case position of the selected reflection feature in the reflection image and position of the matched reference feature and/or relative displacement of the selected reflection feature and the matched reference feature are known, longitudinal coordinate of the corresponding object feature may be determined by triangulation. Thus, the evaluation device may be adapted to select, for example subsequent and/or column by column, a reflection feature and to determine for each potential position of the reference feature the corresponding distance value using triangulation. Displacement and corresponding distance value may be stored in at least one storage device of the evaluation device. The evaluation device may, as an example, comprise at least one data processing device, such as at least one processor, at least one DSP, at least one FPGA and/or at least one ASIC. Further, for storing the at least one predetermined or determinable relationship between the longitudinal coordinate z and the displacement, the at least one data storage device may be provided, such as for providing one or more look-up tables for storing the predetermined relationship. The evaluation device may be adapted to store parameters for an intrinsic and/or extrinsic calibration of the camera and/or the detector. The evaluation device may be adapted to generate the parameters for an intrinsic and/or extrinsic calibration of the camera and/or the detector such as by performing a Tsai camera calibration. The evaluation device may be adapted to compute and/or estimate parameters such as the focal length of the transfer device, the radial lens distortion coefficient, the coordinates of the center of radial lens distortion, scale factors to account for any uncertainty due to imperfections in hardware timing for scanning and digitization, rotation angles for the transformation between the world and camera coordinates, translation components for the transformation between the world and camera coordinates, aperture angles, image sensor format, principal point, skew coefficients, camera center, camera heading, baseline, rotation or translation parameters between camera and/or illumination source, apertures, focal distance, or the like.

Using the combined sensor signal allows to estimate distances, such as the longitudinal coordinate z within the error interval. By determining the displacement region corresponding to the estimated longitudinal coordinate and the corresponding error interval allows to reduce the possible number of solutions along the epipolar line significantly. The number of possible solutions may even be reduced to one. Determining of the longitudinal coordinate z and the error interval may be performed during a pre-evaluation before matching the selected reflection feature and reference feature. This may allow reducing the computational demand such that it is possible to significantly reduce costs and to allow a use in mobile device or outdoor devices. Furthermore, generally in triangulation systems the baseline has to be large in order to detect large distances. Pre-evaluation of the longitudinal coordinate z and error interval using the combined sensor signal and subsequent matching of the selected reflection feature and reference feature may allow using short baselines such that it may be possible to provide a compact device. Furthermore, pre-evaluation of the longitudinal coordinate z and error interval using the combined sensor signal and subsequent matching of the selected reflection feature and reference feature

may enhance accuracy and/or speed and/or may lower computational demand in comparison to conventional triangulation systems. Further, the number of illumination features such as the number of illumination points in the illumination pattern may be reduced to increase the light intensity in each illumination point such as to compete with ambient light while complying to eye safety regulations. A reduced number of illumination features in a conventional triangulation system might increase the difficulty to match reflection features and reference features. Further, the number of illumination features such as the number of illumination points in the illumination pattern may be increased, such as to increase the resolution of the distance measurement, such as to increase the resolution of the obtained depth map without increasing the processing power of the evaluation device such as in a mobile application.

The detector may further comprise an illumination source. As an example, the illumination source may be configured for generating an illuminating light beam for illuminating the object. The detector may be configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector. For this purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

The illumination source may be adapted to generate at least one illumination pattern for illumination of the object. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. The detector may be configured such that the illumination pattern propagates from the detector, in particular from at least one opening of the housing, towards the object along and/or parallel to an optical axis of the detector. For this purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illumination pattern such that it propagates along or parallel to the optical axis. Specifically, the illumination source may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. As used herein, the term "pattern" refers to an arbitrary known or pre-determined arrangement comprising at least one arbitrarily shaped feature. The pattern may comprise at least one feature such as a point or symbol. The pattern may comprise a plurality of features. The pattern may comprise an arrangement of periodic or non-periodic features. As used herein, the term "illumination pattern" refers to a pattern which illuminates the object. The illumination pattern may be generated by ambient light, such as by at least one ambient light source, or by the at least one illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern; a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines. For example, the illumination source may be adapted to generate and/or to project a cloud of points. The illumination pattern may comprise regular and/or constant and/or periodic pattern

such as a triangular pattern, a rectangular pattern, a hexagonal pattern, or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that a hexagonal pattern may be preferred. A distance between two features of the illumination pattern and/or an area of the at least one illumination feature may depend on the circle of confusion in the image.

The illumination source may comprise one or more of at least one light projector; at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The illumination source may comprise at least one light source adapted to generate the illumination pattern directly. For example, the illumination source may comprise at least one laser source. For example, the illumination source may comprise at least one line laser. The line laser may be adapted to send a laser line to the object, for example a horizontal or vertical laser line. The illumination source may comprise a plurality of line lasers. For example, the illumination source may comprise at least two line lasers which may be arranged such that the illumination pattern comprises at least two parallel or crossing lines. The illumination source may comprise the at least one light projector adapted to generate a cloud of points such that the illumination pattern may comprise a plurality of point pattern. The illumination source may comprise at least one mask adapted to generate the illumination pattern from at least one light beam generated by the illumination source. The illumination source may be one of attached to or integrated into a mobile device such as a smartphone. The illumination source may be used for further functions that may be used in determining an image such as for an autofocus function. The illumination device may be attached to a mobile device such as by using a connector such as a USB- or phone-connector such as the headphone jack.

The illumination source, specifically, may be configured for emitting light in the infrared spectral range. It shall be noted, however, that other spectral ranges are feasible, additionally or alternatively. Further, the illumination source specifically may be configured for emitting modulated or non-modulated light. In case a plurality of illumination sources is used, the different illumination sources may have different modulation frequencies which, as outlined in further detail below, later on may be used for distinguishing the light beams. The detector may be configured for evaluating a single light beam or a plurality of light beams. In case a plurality of light beams propagates from the object to the detector, means for distinguishing the light beams may be provided. Thus, the light beams may have different spectral properties, and the detector may comprise one or more wavelength selective elements for distinguishing the different light beams. Each of the light beams may then be evaluated independently. The wavelength selective elements, as an example, may be or may comprise one or more filters, one or more prisms, one or more gratings, one or more dichroitic mirrors or arbitrary combinations thereof. Further, additionally or alternatively, for distinguishing two or more light beams, the light beams may be modulated in a specific fashion. Thus, as an example, the light beams may be frequency modulated, and the sensor signals may be demodulated in order to distinguish partially the sensor signals originating from the different light beams, in accordance with their demodulation frequencies. These techniques generally are known to the skilled person in the field of high-

frequency electronics. Generally, the evaluation device may be configured for distinguishing different light beams having different modulations.

Specifically, the illumination source and the optical sensors may be arranged in a common plane or in different planes. The illumination source and the optical sensors may have different spatial orientation. In particular, the illumination source and the sensor element may be arranged in a twisted arrangement.

The illumination source may be adapted to generate and/or to project a cloud of points such that a plurality of illuminated regions is generated on the matrix of optical sensors, for example the CMOS detector. Additionally, disturbances may be present on the matrix of optical sensors such as disturbances due to speckles and/or extraneous light and/or multiple reflections. The evaluation device may be adapted to determine at least one region of interest, for example one or more pixels illuminated by the light beam which are used for determination of the longitudinal coordinate of the object. For example, the evaluation device may be adapted to perform a filtering method, for example, a blob-analysis and/or an edge filter and/or object recognition method.

The sensor element may be adapted to determine at least one reflection pattern. As used herein, the term "reflection pattern" refers to a response pattern generated by reflection or scattering of light at the surface of the object, in particular generated by the object in response to illumination by the illumination pattern. As outlined above, the illumination pattern comprises at least one feature adapted to illuminate the object. As outlined above, the illumination feature may be generated by ambient light or by the at least one illumination source. The reflection pattern may comprise at least one feature corresponding to at least one feature of the illumination pattern.

The reflection pattern may comprise, in comparison to the illumination pattern, at least one distorted pattern, wherein the distortion depends on the distance of the object, such as surface properties of the object. The evaluation device may be adapted to select at least one feature of the reflection pattern and to determine the longitudinal region of the selected feature of the reflection pattern by evaluating the combined signal Q from the sensor signals, as described above.

For example, the reference image may be an image of the illumination pattern at an image plane at a position of the illumination source. The evaluation device may be adapted to determine the displacement region in the reference image corresponding to the longitudinal region of the selected feature of the reflection pattern. The evaluation device may be adapted to match the selected feature of the reflection pattern with at least one feature of the reference pattern within the displacement region. The illumination source and the sensor element may be separated by a fixed distance.

For example, the detector may comprise at least two sensor elements each having a matrix of optical sensors. At least one first sensor element and at least one second sensor element may be positioned at different spatial positions. A relative distance between the first sensor element and the second element may be fixed. The at least one first sensor element may be adapted to

- determine at least one first reflection pattern, in particular at least one first reflection feature, and the at least one second sensor element may be adapted to determine at least one second reflection pattern, in particular at least one second reflection feature. The evaluation device may be adapted to select at least one image determined by the first sensor element or the second sensor element as reflection image and to select at least one image determined by the other one of the first sensor element or the second sensor element as reference image. The evaluation device may be adapted to select the at least one reflection feature in the reflection pattern and to determine the longitudinal region of the selected feature by evaluating the combined signal Q from the sensor signals. The evaluation device may be adapted to determine the displacement region in the reference image corresponding to the longitudinal region of the selected feature of the reflection pattern. The evaluation device may be adapted to match the selected feature of the reflection pattern with at least one feature of the reference pattern within the displacement region.
- 15 As outlined above, the detector may further comprise one or more additional elements such as one or more additional optical elements. Further, the detector may fully or partially be integrated into at least one housing.

- In a further aspect of the present invention, a detector system for determining a position of at least one object is disclosed. The detector system comprises at least one detector according to the present invention, such as according to one or more of the embodiments disclosed above or according to one or more of the embodiments disclosed in further detail below. The detector system further comprises at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object. Further details regarding the beacon device will be given below, including potential embodiments thereof. Thus, the at least one beacon device may be or may comprise at least one active beacon device, comprising one or more illumination sources such as one or more light sources like lasers, LEDs, light bulbs or the like. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Alternatively, as outlined above, the infrared spectral range may be used, such as in the range of 780 nm to 3.0 μm . Specifically, the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm may be used. The light emitted by the one or more beacon devices may be non-modulated or may be modulated, as outlined above, in order to distinguish two or more light beams. Additionally or alternatively, the at least one beacon device may be adapted to reflect one or more light beams towards the detector, such as by comprising one or more reflective elements. Further, the at least one beacon device may be or may comprise one or more scattering elements adapted for scattering a light beam. Therein, elastic or inelastic scattering may be used. In case the at least one beacon device is adapted to reflect and/or scatter a primary light beam towards the detector, the beacon device may be adapted to leave the spectral properties of the light beam unaffected or, alternatively, may be adapted to change the spectral properties of the light beam, such as by modifying a wavelength of the light beam.

In a further aspect of the present invention, a human-machine interface for exchanging at least one item of information between a user and a machine is disclosed. The human-machine interface comprises at least one detector system according to the embodiments disclosed above and/or according to one or more of the embodiments disclosed in further detail below. Therein,
5 the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user or held by the user. The human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to assign to the position at least one item of information.

- 10 In a further aspect of the present invention, an entertainment device for carrying out at least one entertainment function is disclosed. The entertainment device comprises at least one human-machine interface according to the embodiment disclosed above and/or according to one or more of the embodiments disclosed in further detail below. The entertainment device is configured to enable at least one item of information to be input by a player by means of the human-machine interface. The entertainment device is further configured to vary the entertainment
15 function in accordance with the information.

- In a further aspect of the present invention, a tracking system for tracking a position of at least one movable object is disclosed. The tracking system comprises at least one detector system
20 according to one or more of the embodiments referring to a detector system as disclosed above and/or as disclosed in further detail below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time.

- 25 In a further aspect of the present invention, a camera for imaging at least one object is disclosed. The camera comprises at least one detector according to any one of the embodiments referring to a detector as disclosed above or as disclosed in further detail below.

- 30 In a further aspect of the present invention, a scanning system for determining a depth profile of a scenery, which may also imply determining at least one position of at least one object, is provided. The scanning system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The scanning system further
35 comprises at least one illumination source adapted to scan the scenery with at least one light beam, which may also be referred to as an illumination light beam or scanning light beam. As used herein, the term "scenery" generally refers to a two-dimensional or three-dimensional range which is visible by the detector, such that at least one geometric or spatial property of the two-dimensional or three-dimensional range may be evaluated with the detector. As further
40 used herein, the term "scan" generally refers to a consecutive measurement in different regions. Thus, the scanning specifically may imply at least one first measurement with the illumination light beam being oriented or directed in a first fashion, and at least one second measurement with the illumination light beam being oriented or directed in a second fashion which is different

from the first fashion. The scanning may be a continuous scanning or a stepwise scanning. Thus, in a continuous or stepwise fashion, the illumination light beam may be directed into different regions of the scenery, and the detector may be detected to generate at least one item of information, such as at least one longitudinal coordinate, for each region. As an example, for
5 scanning an object, one or more illumination light beams may, continuously or in a stepwise fashion, create light spots on the surface of the object, wherein longitudinal coordinates are generated for the light spots. Alternatively, however, a light pattern may be used for scanning. The scanning may be a point scanning or a line scanning or even a scanning with more complex light patterns. The illumination source of the scanning system may be distinct from the optional illumination source of the detector. Alternatively, however, the illumination source of the
10 scanning system may also be fully or partially identical with or integrated into the at least one optional illumination source of the detector.

Thus, the scanning system may comprise at least one illumination source which is adapted to
15 emit the at least one light beam being configured for the illumination of the at least one dot located at the at least one surface of the at least one object. As used herein, the term "dot" refers to an area, specifically a small area, on a part of the surface of the object which may be selected, for example by a user of the scanning system, to be illuminated by the illumination source. Preferably, the dot may exhibit a size which may, on one hand, be as small as possible in order
20 to allow the scanning system to determine a value for the distance between the illumination source comprised by the scanning system and the part of the surface of the object on which the dot may be located as exactly as possible and which, on the other hand, may be as large as possible in order to allow the user of the scanning system or the scanning system itself, in particular by an automatic procedure, to detect a presence of the dot on the related part of the surface of the object.
25

For this purpose, the illumination source may comprise an artificial illumination source, in particular at least one laser source and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic
30 and/or inorganic light-emitting diode. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Additionally or alternatively, light in the infrared spectral range may be used, such as in the range of 780 nm to 3.0 μm . Specifically, the light in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm may be used. On account of their generally defined beam profiles and other
35 properties of handleability, the use of at least one laser source as the illumination source is particularly preferred. Herein, the use of a single laser source may be preferred, in particular in a case in which it may be important to provide a compact scanning system that might be easily storable and transportable by the user. The illumination source may, thus, preferably be a constituent part of the detector and may, therefore, in particular be integrated into the detector,
40 such as into the housing of the detector. In a preferred embodiment, particularly the housing of the scanning system may comprise at least one display configured for providing distance-related information to the user, such as in an easy-to-read manner. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least

one button which may be configured for operating at least one function related to the scanning system, such as for setting one or more operation modes. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least one fastening unit which may be configured for fastening the scanning system to a further surface, such as a rubber foot, a base plate or a wall holder, such as a base plate or holder comprising a magnetic material, in particular for increasing the accuracy of the distance measurement and/or the handleability of the scanning system by the user.

Particularly, the illumination source of the scanning system may, thus, emit a single laser beam which may be configured for the illumination of a single dot located at the surface of the object. By using at least one of the detectors according to the present invention at least one item of information about the distance between the at least one dot and the scanning system may, thus, be generated. Hereby, preferably, the distance between the illumination system as comprised by the scanning system and the single dot as generated by the illumination source may be determined, such as by employing the evaluation device as comprised by the at least one detector. However, the scanning system may, further, comprise an additional evaluation system which may, particularly, be adapted for this purpose. Alternatively or in addition, a size of the scanning system, in particular of the housing of the scanning system, may be taken into account and, thus, the distance between a specific point on the housing of the scanning system, such as a front edge or a back edge of the housing, and the single dot may, alternatively, be determined. The illumination source may be adapted to generate and/or to project a cloud of points, for example the illumination source may comprise one or more of at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources.

Alternatively, the illumination source of the scanning system may emit two individual laser beams which may be configured for providing a respective angle, such as a right angle, between the directions of an emission of the beams, whereby two respective dots located at the surface of the same object or at two different surfaces at two separate objects may be illuminated. However, other values for the respective angle between the two individual laser beams may also be feasible. This feature may, in particular, be employed for indirect measuring functions, such as for deriving an indirect distance which may not be directly accessible, such as due to a presence of one or more obstacles between the scanning system and the dot or which may otherwise be hard to reach. By way of example, it may, thus, be feasible to determine a value for a height of an object by measuring two individual distances and deriving the height by using the Pythagoras formula. In particular for being able to keep a predefined level with respect to the object, the scanning system may, further, comprise at least one leveling unit, in particular an integrated bubble vial, which may be used for keeping the predefined level by the user.

As a further alternative, the illumination source of the scanning system may emit a plurality of individual laser beams, such as an array of laser beams which may exhibit a respective pitch, in particular a regular pitch, with respect to each other and which may be arranged in a manner in

order to generate an array of dots located on the at least one surface of the at least one object. For this purpose, specially adapted optical elements, such as beam-splitting devices and mirrors, may be provided which may allow a generation of the described array of the laser beams. In particular, the illumination source may be directed to scan an area or a volume by using one or more movable mirrors to redirect the light beam in a periodic or non-periodic fashion.

Thus, the scanning system may provide a static arrangement of the one or more dots placed on the one or more surfaces of the one or more objects. Alternatively, the illumination source of the scanning system, in particular the one or more laser beams, such as the above described array of the laser beams, may be configured for providing one or more light beams which may exhibit a varying intensity over time and/or which may be subject to an alternating direction of emission in a passage of time, in particular by moving one or more mirrors, such as the micro-mirrors comprised within the mentioned array of micro-mirrors. As a result, the illumination source may be configured for scanning a part of the at least one surface of the at least one object as an image by using one or more light beams with alternating features as generated by the at least one illumination source of the scanning system. In particular, the scanning system may, thus, use at least one row scan and/or line scan, such as to scan the one or more surfaces of the one or more objects sequentially or simultaneously. Thus, the scanning system may be adapted to measure angles by measuring three or more dots, or the scanning system may be adapted to measure corners or narrow regions such as a gable of a roof, which may be hardly accessible using a conventional measuring stick. As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step. As non-limiting examples, the scanning system may be used in industrial safety curtain applications. As non-limiting examples, the scanning system may be used to perform sweeping, vacuuming, mopping, or waxing functions, or yard or garden care functions such as mowing or raking. As non-limiting examples, the scanning system may employ an LED illumination source with collimated optics and may be adapted to shift the frequency of the illumination source to a different frequency to obtain more accurate results and/or employ a filter to attenuate certain frequencies while transmitting others. As non-limiting examples, the scanning system and/or the illumination source may be rotated as a whole or rotating only a particular optics package such as a mirror, beam splitter or the like, using a dedicated motor as such that in operation, the scanning system may have a full 360 degree view or even be moved and or rotated out of plane to further increase the scanned area. Further, the illumination source may be actively aimed in a predetermined direction. Further, to allow the rotation of wired electrical systems, slip rings, optical data transmission, or inductive couplings may be employed.

As a non-limiting example, the scanning system may be attached to a tripod and point towards an object or region with several corners and surfaces. One or more flexibly movable laser sources are attached to the scanning system. The one or more laser sources are moved as

such that they illuminate points of interest. The position of the illuminated points with respect to the scanning system is measured when pressing a designated button on the scanning system and the position information is transmitted via a wireless interface to a mobile phone. The position information is stored in a mobile phone application. The laser sources are moved to illuminate further points of interest the position of which are measured and transmitted to the mobile phone application. The mobile phone application may transform the set of points into a 3d model by connecting adjacent points with planar surfaces. The 3d model may be stored and processed further. The distances and or angles between the measured points or surfaces may be displayed directly on a display attached to a scanning system or on the mobile phone to which the position information is transmitted.

As a non-limiting example, a scanning system may comprise two or more flexible movable laser sources to project points and further one movable laser source projecting a line. The line may be used to arrange the two or more laser spots along a line and the display of the scanning system may display the distance between the two or more laser spots that may be arranged along the line, such as at equal distance. In the case of two laser spots, a single laser source may be used whereas the distance of the projected points is modified using one or more beam-splitters or prisms, where a beam-splitter or prism can be moved as such that the projected laser spots move apart or closer together. Further, the scanning system may be adapted to project further patterns such as a right angle, a circle, a square, a triangle, or the like, along which a measurement can be done by projecting laser spots and measuring their position.

As a non-limiting example, the scanning system may be adapted as a line scanning device. In particular, the scanning system may comprise at least one sensor line or row. Triangulation systems require a sufficient baseline such that in the near field no detection may be possible. Near field detection may be possible if the laser spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. These near field and far field problems can be overcome by using the detector according to the present invention. In particular, the detector may comprise a CMOS line of optical sensors. The scanning system may be adapted to detect a plurality of light beams propagating from the object to the detector on the CMOS line. The light beams may be generated at different positions on the object or by movement of the illumination source. The scanning system may be adapted to determine at least one longitudinal coordinate for each of the light points by determining the quotient signal Q as described above and in more detail below.

As a non-limiting example, the scanning system may be adapted to support the work with tools, such as wood or metal processing tools, such as a saw, a drill, or the like. Thus, the scanning system may be adapted to measure the distance in two opposite directions and display the two measured distances or the sum of the distances in a display. Further, the scanning system may be adapted to measure the distance to the edge of a surface as such that when the scanning system is placed on the surface, a laser point is moved automatically away from the scanning system along the surface, until the distance measurement shows a sudden change due to a corner or the edge of a surface. This makes it possible to measure the distance of the end of a

wood plank while the scanning system is placed on the plank but remote from its end. Further, the scanning system may measure the distance of the end of a plank in one direction and project a line or circle or point in a designated distance in the opposite direction. The scanning system may be adapted to project the line or circle or point in a distance depending on the distance measured in the opposite direction such as depending on a predetermined sum distance. This allows working with a tool such as a saw or driller at the projected position while placing the scanning system in a safe distance from the tool and simultaneously perform a process using the tool in a predetermined distance to the edge of the plank. Further, the scanning system may be adapted to project points or lines or the like in two opposite directions in a predetermined distance. When the sum of the distances is changed, only one of the projected distances changes.

As a non-limiting example, the scanning system may be adapted to be placed onto a surface, such as a surface on which a task is performed, such as cutting, sawing, drilling, or the like, and to project a line onto the surface in a predetermined distance that can be adjusted such as with buttons on the scanning system.

As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step.

The transfer device can, as explained above, be designed to feed light propagating from the object to the detector to the optical sensor, preferably successively. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the optical sensor. The transfer device can also be wholly or partly a constituent part of at least one optional illumination source, for example by the illumination source being designed to provide a light beam having defined optical properties, for example having a defined or precisely known beam profile, for example at least one linear combination of Gaussian beams, in particular at least one laser beam having a known beam profile.

For potential embodiments of the optional illumination source, reference may be made to WO 2012/110924 A1. Still, other embodiments are feasible. Light emerging from the object can originate in the object itself, but can also optionally have a different origin and propagate from this origin to the object and subsequently toward the transversal and/or longitudinal optical sensor. The latter case can be effected for example by at least one illumination source being used. This illumination source can for example be or comprise an ambient illumination source and/or may be or may comprise an artificial illumination source. By way of example, the detector itself can comprise at least one illumination source, for example at least one laser and/or at least one in-

candescent lamp and/or at least one semiconductor illumination source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. On account of their generally defined beam profiles and other properties of handleability, the use of one or a plurality of lasers as illumination source or as part thereof, is particularly preferred. The illumination source itself can be a constituent part of the detector or else be formed independently of the detector. The illumination source can be integrated in particular into the detector, for example a housing of the detector. Alternatively or additionally, at least one illumination source can also be integrated into the at least one beacon device or into one or more of the beacon devices and/or into the object or connected or spatially coupled to the object.

The light emerging from the one or more optional beacon devices can accordingly, alternatively or additionally from the option that said light originates in the respective beacon device itself, emerge from the illumination source and/or be excited by the illumination source. By way of example, the electromagnetic light emerging from the beacon device can be emitted by the beacon device itself and/or be reflected by the beacon device and/or be scattered by the beacon device before it is fed to the detector. In this case, emission and/or scattering of the electromagnetic radiation can be effected without spectral influencing of the electromagnetic radiation or with such influencing. Thus, by way of example, a wavelength shift can also occur during scattering, for example according to Stokes or Raman. Furthermore, emission of light can be excited, for example, by a primary illumination source, for example by the object or a partial region of the object being excited to generate luminescence, in particular phosphorescence and/or fluorescence. Other emission processes are also possible, in principle. If a reflection occurs, then the object can have for example at least one reflective region, in particular at least one reflective surface. Said reflective surface can be a part of the object itself, but can also be for example a reflector which is connected or spatially coupled to the object, for example a reflector plaque connected to the object. If at least one reflector is used, then it can in turn also be regarded as part of the detector which is connected to the object, for example, independently of other constituent parts of the detector.

The beacon devices and/or the at least one optional illumination source generally may emit light in at least one of: the ultraviolet spectral range, preferably in the range of 200 nm to 380 nm; the visible spectral range (380 nm to 780 nm); the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers, more preferably in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm. For thermal imaging applications the target may emit light in the far infrared spectral range, preferably in the range of 3.0 micrometers to 20 micrometers. For example, the at least one illumination source is adapted to emit light in the visible spectral range, preferably in the range of 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm. For example, the at least one illumination source is adapted to emit light in the infrared spectral range. Other options, however, are feasible.

The feeding of the light beam to the optical sensor can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is pro-

duced on the optional sensor area of the optical sensor. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects can be detected. Preferably, the transfer device may be designed in such a way that the light spot, for example in the case of an object arranged within a visual range of the detector, is arranged completely on a sensor region and/or on a sensor area of the optical sensor. By way of example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

In a further aspect, the present invention discloses a method for determining a position of at least one object by using a detector, such as a detector according to the present invention, such as according to one or more of the embodiments referring to a detector as disclosed above or as disclosed in further detail below. Still, other types of detectors may be used. The method comprises the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed. Further, one, more than one or even all of the method steps may be performed repeatedly.

The method comprises the following method steps:

- generating at least two sensor signals in response to an illumination of at least one sensor element having a matrix of optical sensors by at least one reflection light beam propagating from the object to the detector, the optical sensors each having a light-sensitive area;
- determining at least one reflection image by using the sensor element;
- selecting at least one reflection feature of the reflection image and evaluating the sensor signals by using at least one evaluation device, thereby, determining at least one longitudinal region of the selected reflection feature, wherein the evaluating comprises evaluating a combined signal Q from the sensor signals;
- determining at least one displacement region in at least one reference image corresponding to the longitudinal region;
- matching the selected reflection feature with at least one reference feature within the displacement region.

For details, options and definitions, reference may be made to the detector as discussed above. Thus, specifically, as outlined above, the method may comprise using the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below.

The method may further comprise determining a displacement of the matched reference feature and the selected reflection feature. A longitudinal information of the matched feature may be determined using a predetermined relationship between a longitudinal coordinate and the displacement.

The deriving of the combined signal Q may comprise one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

5 In a further aspect of the present invention, use of the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below, is proposed, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a tracking application; a photography application; an imaging application or camera application; a mapping application for generating maps of at least one space; a homing or tracking beacon detector for vehicles; an outdoor application; a mobile application; a communication application; a machine vision application; a robotics application; a quality control application; a manufacturing application.

15 The object generally may be a living or non-living object. The detector or the detector system even may comprise the at least one object, the object thereby forming part of the detector system. Preferably, however, the object may move independently from the detector, in at least one spatial dimension. The object generally may be an arbitrary object. In one embodiment, the object may be a rigid object. Other embodiments are feasible, such as embodiments in which the object is a non-rigid object or an object which may change its shape.

25 As will be outlined in further detail below, the present invention may specifically be used for tracking positions and/or motions of a person, such as for the purpose of controlling machines, gaming or simulation of sports. In this or other embodiments, specifically, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat; an article of clothing; a hat; a shoe.

30 Thus, generally, the devices according to the present invention, such as the detector, may be applied in various fields of uses. Specifically, the detector may be applied for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a human-machine interface application; a tracking application; a photography application; a mapping application for generating maps of at least one space, such as at least one space selected from the group of a room, a building and a street; a mobile application; a webcam; an audio device; a dolby surround audio system; a computer peripheral device; a gaming application; a camera or video application; a security application; a surveillance application; an automotive application; a transport application; a medical application; a sports' application; a machine vision application; a vehicle application; an airplane application; a ship application; a spacecraft application; a building application; a construction application; a cartography application; a manufacturing application. Additionally or alternatively, applications in local and/or global positioning systems may be named, especially landmark-based positioning and/or navigation, specifically for use in cars or other vehicles (such as trains, motorcycles, bicycles, trucks for cargo transportation), robots or for use by pedestrians. Further, indoor positioning systems may be named as potential applications, such as for house-

hold applications and/or for robots used in manufacturing, logistics, surveillance, or maintenance technology.

5 The devices according to the present invention may be used in mobile phones, tablet computers, laptops, smart panels or other stationary or mobile or wearable computer or communication applications. Thus, the devices according to the present invention may be combined with at least one active light source, such as a light source emitting light in the visible range or infrared spectral range, in order to enhance performance. Thus, as an example, the devices according to the present invention may be used as cameras and/or sensors, such as in combination with
10 mobile software for scanning and/or detecting environment, objects and living beings. The devices according to the present invention may even be combined with 2D cameras, such as conventional cameras, in order to increase imaging effects. The devices according to the present invention may further be used for surveillance and/or for recording purposes or as input devices to control mobile devices, especially in combination with voice and/or gesture recognition. Thus,
15 specifically, the devices according to the present invention acting as human-machine interfaces, also referred to as input devices, may be used in mobile applications, such as for controlling other electronic devices or components via the mobile device, such as the mobile phone. As an example, the mobile application including at least one device according to the present invention may be used for controlling a television set, a game console, a music player or music device or
20 other entertainment devices.

Further, the devices according to the present invention may be used in webcams or other peripheral devices for computing applications. Thus, as an example, the devices according to the present invention may be used in combination with software for imaging, recording, surveillance,
25 scanning or motion detection. As outlined in the context of the human-machine interface and/or the entertainment device, the devices according to the present invention are particularly useful for giving commands by facial expressions and/or body expressions. The devices according to the present invention can be combined with other input generating devices like e.g. mouse, keyboard, touchpad, microphone etc. Further, the devices according to the present invention may be used in applications for gaming, such as by using a webcam. Further, the devices according to the present invention may be used in virtual training applications and/or video conferences. Further, devices according to the present invention may be used to recognize or track hands, arms, or objects used in a virtual or augmented reality application, especially when wearing head-mounted displays.

35 Further, the devices according to the present invention may be used in mobile audio devices, television devices and gaming devices, as partially explained above. Specifically, the devices according to the present invention may be used as controls or control devices for electronic devices, entertainment devices or the like. Further, the devices according to the present invention
40 may be used for eye detection or eye tracking, such as in 2D- and 3D-display techniques, especially with transparent displays for augmented reality applications and/or for recognizing whether a display is being looked at and/or from which perspective a display is being looked at. Further, devices according to the present invention may be used to explore a room, boundaries,

obstacles, in connection with a virtual or augmented reality application, especially when wearing a head-mounted display.

Further, the devices according to the present invention may be used in or as digital cameras such as DSC cameras and/or in or as reflex cameras such as SLR cameras. For these applications, reference may be made to the use of the devices according to the present invention in mobile applications such as mobile phones, as disclosed above.

Further, the devices according to the present invention may be used for security or surveillance applications. Thus, as an example, at least one device according to the present invention can be combined with one or more digital and/or analogue electronics that will give a signal if an object is within or outside a predetermined area (e.g. for surveillance applications in banks or museums). Specifically, the devices according to the present invention may be used for optical encryption. Detection by using at least one device according to the present invention can be combined with other detection devices to complement wavelengths, such as with IR, x-ray, UV-VIS, radar or ultrasound detectors. The devices according to the present invention may further be combined with an active infrared light source to allow detection in low light surroundings. The devices according to the present invention are generally advantageous as compared to active detector systems, specifically since the devices according to the present invention avoid actively sending signals which may be detected by third parties, as is the case e.g. in radar applications, ultrasound applications, LIDAR or similar active detector devices. Thus, generally, the devices according to the present invention may be used for an unrecognized and undetectable tracking of moving objects. Additionally, the devices according to the present invention generally are less prone to manipulations and irritations as compared to conventional devices.

Further, given the ease and accuracy of 3D detection by using the devices according to the present invention, the devices according to the present invention generally may be used for facial, body and person recognition and identification. Therein, the devices according to the present invention may be combined with other detection means for identification or personalization purposes such as passwords, finger prints, iris detection, voice recognition or other means. Thus, generally, the devices according to the present invention may be used in security devices and other personalized applications.

Further, the devices according to the present invention may be used as 3D barcode readers for product identification.

In addition to the security and surveillance applications mentioned above, the devices according to the present invention generally can be used for surveillance and monitoring of spaces and areas. Thus, the devices according to the present invention may be used for surveying and monitoring spaces and areas and, as an example, for triggering or executing alarms in case prohibited areas are violated. Thus, generally, the devices according to the present invention may be used for surveillance purposes in building surveillance or museums, optionally in combination with other types of sensors, such as in combination with motion or heat sensors, in

combination with image intensifiers or image enhancement devices and/or photomultipliers. Further, the devices according to the present invention may be used in public spaces or crowded spaces to detect potentially hazardous activities such as commitment of crimes such as theft in a parking lot or unattended objects such as unattended baggage in an airport.

5

Further, the devices according to the present invention may advantageously be applied in camera applications such as video and camcorder applications. Thus, the devices according to the present invention may be used for motion capture and 3D-movie recording. Therein, the devices according to the present invention generally provide a large number of advantages over conventional optical devices. Thus, the devices according to the present invention generally require a lower complexity with regard to optical components. Thus, as an example, the number of lenses may be reduced as compared to conventional optical devices, such as by providing the devices according to the present invention having one lens only. Due to the reduced complexity, very compact devices are possible, such as for mobile use. Conventional optical systems having two or more lenses with high quality generally are voluminous, such as due to the general need for voluminous beam-splitters. Further, the devices according to the present invention generally may be used for focus/autofocus devices, such as autofocus cameras. Further, the devices according to the present invention may also be used in optical microscopy, especially in confocal microscopy.

20

Further, the devices according to the present invention generally are applicable in the technical field of automotive technology and transport technology. Thus, as an example, the devices according to the present invention may be used as distance and surveillance sensors, such as for adaptive cruise control, emergency brake assist, lane departure warning, surround view, blind spot detection, traffic sign detection, traffic sign recognition, lane recognition, rear cross traffic alert, light source recognition for adapting the head light intensity and range depending on approaching traffic or vehicles driving ahead, adaptive frontlighting systems, automatic control of high beam head lights, adaptive cut-off lights in front light systems, glare-free high beam front lighting systems, marking animals, obstacles, or the like by headlight illumination, rear cross traffic alert, and other driver assistance systems such as advanced driver assistance systems, or other automotive and traffic applications. Further, devices according to the present invention may be used in driver assistance systems anticipating maneuvers of the driver beforehand for collision avoidance or the like. Further, the devices according to the present invention can also be used for velocity and/or acceleration measurements, such as by analyzing a first and second time-derivative of position information gained by using the detector according to the present invention. This feature generally may be applicable in automotive technology, transportation technology or general traffic technology. Applications in other fields of technology are feasible. A specific application in an indoor positioning system may be the detection of positioning of passengers in transportation, more specifically to electronically control the use of safety systems such as airbags. The use of an airbag may be prevented in case the passenger is located as such, that the use of an airbag will cause a severe injury. Further, in vehicles such as cars, trains, planes or the like, especially in autonomous vehicles, devices according to the present

40

invention may be used to determine whether a driver pays attention to the traffic or is distracted, or asleep, or tired, or incapable of driving such as due to the consumption of alcohol or the like.

5 In these or other applications, generally, the devices according to the present invention may be used as standalone devices or in combination with other sensor devices, such as in combination with radar and/or ultrasonic devices. Specifically, the devices according to the present invention may be used for autonomous driving and safety issues. Further, in these applications, the devices according to the present invention may be used in combination with infrared sensors, radar sensors, which are sonic sensors, two-dimensional cameras or other types of sensors. In these applications, the generally passive nature of the devices according to the present invention is advantageous. Thus, since the devices according to the present invention generally do not require emitting signals, the risk of interference of active sensor signals with other signal sources may be avoided. The devices according to the present invention specifically may be used in combination with recognition software, such as standard image recognition software. 10 Thus, signals and data as provided by the devices according to the present invention typically are readily processable and, therefore, generally require lower calculation power than established 3D measurement systems. Given the low space demand, the devices according to the present invention such as cameras may be placed at virtually any place in a vehicle, such as on or behind a window screen, on a front hood, on bumpers, on lights, on mirrors or other places and the like. Various detectors according to the present invention such as one or more detectors based on the effect disclosed within the present invention can be combined, such as in order to allow autonomously driving vehicles or in order to increase the performance of active safety concepts. Thus, various devices according to the present invention may be combined with one or more other devices according to the present invention and/or conventional sensors, 20 such as in the windows like rear window, side window or front window, on the bumpers or on the lights. 25

A combination of at least one device according to the present invention such as at least one detector according to the present invention with one or more rain detection sensors is also possible. This is due to the fact that the devices according to the present invention generally are advantageous over conventional sensor techniques such as radar, specifically during heavy rain. A combination of at least one device according to the present invention with at least one conventional sensing technique such as radar may allow for a software to pick the right combination of signals according to the weather conditions. 30

35 Further, the devices according to the present invention generally may be used as break assist and/or parking assist and/or for speed measurements. Speed measurements can be integrated in the vehicle or may be used outside the vehicle, such as in order to measure the speed of other cars in traffic control. Further, the devices according to the present invention may be used for detecting free parking spaces in parking lots. 40

Further, the devices according to the present invention may be used in the fields of medical systems and sports. Thus, in the field of medical technology, surgery robotics, e.g. for use in endo-

scopes, may be named, since, as outlined above, the devices according to the present invention may require a low volume only and may be integrated into other devices. Specifically, the devices according to the present invention having one lens, at most, may be used for capturing 3D information in medical devices such as in endoscopes. Further, the devices according to the present invention may be combined with an appropriate monitoring software, in order to enable tracking and analysis of movements. This may allow an instant overlay of the position of a medical device, such as an endoscope or a scalpel, with results from medical imaging, such as obtained from magnetic resonance imaging, x-ray imaging, or ultrasound imaging. These applications are specifically valuable e.g. in medical treatments where precise location information is important such as in brain surgery and long-distance diagnosis and tele-medicine. Further, the devices according to the present invention may be used in 3D-body scanning. Body scanning may be applied in a medical context, such as in dental surgery, plastic surgery, bariatric surgery, or cosmetic plastic surgery, or it may be applied in the context of medical diagnosis such as in the diagnosis of myofascial pain syndrome, cancer, body dysmorphic disorder, or further diseases. Body scanning may further be applied in the field of sports to assess ergonomic use or fit of sports equipment. Further, the devices according to the present invention may be used in wearable robots such as in exoskeletons or prosthesis or the like. Body scanning may further be used in the context of clothing, such as to determine a suitable size and fitting of clothes. This technology may be used in the context of tailor-made clothes or in the context of ordering clothes or shoes from the internet or at a self-service shopping device such as a micro kiosk device or customer concierge device. Body scanning in the context of clothing is especially important for scanning fully dressed customers.

Further, the devices according to the present invention may be used in the context of people counting systems, such as to count the number of people in an elevator, a train, a bus, a car, or a plane, or to count the number of people passing a hallway, a door, an aisle, a retail store, a stadium, an entertainment venue, a museum, a library, a public location, a cinema, a theater, or the like. Further, the 3D-function in the people counting system may be used to obtain or estimate further information about the people that are counted such as height, weight, age, physical fitness, or the like. This information may be used for business intelligence metrics, and/or for further optimizing the locality where people may be counted to make it more attractive or safe. In a retail environment, the devices according to the present invention in the context of people counting may be used to recognize returning customers or cross shoppers, to assess shopping behavior, to assess the percentage of visitors that make purchases, to optimize staff shifts, or to monitor the costs of a shopping mall per visitor. Further, people counting systems may be used for anthropometric surveys. Further, the devices according to the present invention may be used in public transportation systems for automatically charging passengers depending on the length of transport. Further, the devices according to the present invention may be used in playgrounds for children, to recognize injured children or children engaged in dangerous activities, to allow additional interaction with playground toys, to ensure safe use of playground toys or the like.

Further, the devices according to the present invention may be used in construction tools, such as a range meter that determines the distance to an object or to a wall, to assess whether a surface is planar, to align objects or place objects in an ordered manner, or in inspection cameras for use in construction environments or the like.

5

Further, the devices according to the present invention may be applied in the field of sports and exercising, such as for training, remote instructions or competition purposes. Specifically, the devices according to the present invention may be applied in the fields of dancing, aerobic, football, soccer, basketball, baseball, cricket, hockey, track and field, swimming, polo, handball, volleyball, rugby, sumo, judo, fencing, boxing, golf, car racing, laser tag, battlefield simulation etc. The devices according to the present invention can be used to detect the position of a ball, a bat, a sword, motions, etc., both in sports and in games, such as to monitor the game, support the referee or for judgment, specifically automatic judgment, of specific situations in sports, such as for judging whether a point or a goal actually was made.

15

Further, the devices according to the present invention may be used in the field of auto racing or car driver training or car safety training or the like to determine the position of a car or the track of a car, or the deviation from a previous track or an ideal track or the like.

20

The devices according to the present invention may further be used to support a practice of musical instruments, in particular remote lessons, for example lessons of string instruments, such as fiddles, violins, violas, celli, basses, harps, guitars, banjos, or ukuleles, keyboard instruments, such as pianos, organs, keyboards, harpsichords, harmoniums, or accordions, and/or percussion instruments, such as drums, timpani, marimbas, xylophones, vibraphones, bongos, congas, timbales, djembes or tablas.

25

The devices according to the present invention further may be used in rehabilitation and physiotherapy, in order to encourage training and/or in order to survey and correct movements. Therein, the devices according to the present invention may also be applied for distance diagnostics.

30

Further, the devices according to the present invention may be applied in the field of machine vision. Thus, one or more of the devices according to the present invention may be used e.g. as a passive controlling unit for autonomous driving and or working of robots. In combination with moving robots, the devices according to the present invention may allow for autonomous movement and/or autonomous detection of failures in parts. The devices according to the present invention may also be used for manufacturing and safety surveillance, such as in order to avoid accidents including but not limited to collisions between robots, production parts and living beings. In robotics, the safe and direct interaction of humans and robots is often an issue, as robots may severely injure humans when they are not recognized. Devices according to the present invention may help robots to position objects and humans better and faster and allow a safe interaction. Given the passive nature of the devices according to the present invention, the devices according to the present invention may be advantageous over active devices and/or may be used complementary to existing solutions like radar, ultrasound, 2D cameras, IR detec-

40

tion etc. One particular advantage of the devices according to the present invention is the low likelihood of signal interference. Therefore, multiple sensors can work at the same time in the same environment, without the risk of signal interference. Thus, the devices according to the present invention generally may be useful in highly automated production environments like e.g. but not limited to automotive, mining, steel, etc. The devices according to the present invention can also be used for quality control in production, e.g. in combination with other sensors like 2-D imaging, radar, ultrasound, IR etc., such as for quality control or other purposes. Further, the devices according to the present invention may be used for assessment of surface quality, such as for surveying the surface evenness of a product or the adherence to specified dimensions, from the range of micrometers to the range of meters. Other quality control applications are feasible. In a manufacturing environment, the devices according to the present invention are especially useful for processing natural products such as food or wood, with a complex 3-dimensional structure to avoid large amounts of waste material. Further, devices according to the present invention may be used to monitor the filling level of tanks, silos etc. Further, devices according to the present invention may be used to inspect complex products for missing parts, incomplete parts, loose parts, low quality parts, or the like, such as in automatic optical inspection, such as of printed circuit boards, inspection of assemblies or sub-assemblies, verification of engineered components, engine part inspections, wood quality inspection, label inspections, inspection of medical devices, inspection of product orientations, packaging inspections, food pack inspections, or the like.

Further, the devices according to the present invention may be used in vehicles, trains, airplanes, ships, spacecraft and other traffic applications. Thus, besides the applications mentioned above in the context of traffic applications, passive tracking systems for aircraft, vehicles and the like may be named. The use of at least one device according to the present invention, such as at least one detector according to the present invention, for monitoring the speed and/or the direction of moving objects is feasible. Specifically, the tracking of fast moving objects on land, sea and in the air including space may be named. The at least one device according to the present invention, such as the at least one detector according to the present invention, specifically may be mounted on a still-standing and/or on a moving device. An output signal of the at least one device according to the present invention can be combined e.g. with a guiding mechanism for autonomous or guided movement of another object. Thus, applications for avoiding collisions or for enabling collisions between the tracked and the steered object are feasible. The devices according to the present invention generally are useful and advantageous due to the low calculation power required, the instant response and due to the passive nature of the detection system which generally is more difficult to detect and to disturb as compared to active systems, like e.g. radar. The devices according to the present invention are particularly useful but not limited to e.g. speed control and air traffic control devices. Further, the devices according to the present invention may be used in automated tolling systems for road charges.

The devices according to the present invention generally may be used in passive applications. Passive applications include guidance for ships in harbors or in dangerous areas, and for aircraft when landing or starting. Therein, fixed, known active targets may be used for precise

guidance. The same can be used for vehicles driving on dangerous but well defined routes, such as mining vehicles. Further, the devices according to the present invention may be used to detect rapidly approaching objects, such as cars, trains, flying objects, animals, or the like. Further, the devices according to the present invention can be used for detecting velocities or accelerations of objects, or to predict the movement of an object by tracking one or more of its position, speed, and/or acceleration depending on time.

Further, as outlined above, the devices according to the present invention may be used in the field of gaming. Thus, the devices according to the present invention can be passive for use with multiple objects of the same or of different size, color, shape, etc., such as for movement detection in combination with software that incorporates the movement into its content. In particular, applications are feasible in implementing movements into graphical output. Further, applications of the devices according to the present invention for giving commands are feasible, such as by using one or more of the devices according to the present invention for gesture or facial recognition. The devices according to the present invention may be combined with an active system in order to work under e.g. low light conditions or in other situations in which enhancement of the surrounding conditions is required. Additionally or alternatively, a combination of one or more devices according to the present invention with one or more IR or VIS light sources is possible. A combination of a detector according to the present invention with special devices is also possible, which can be distinguished easily by the system and its software, e.g. and not limited to, a special color, shape, relative position to other devices, speed of movement, light, frequency used to modulate light sources on the device, surface properties, material used, reflection properties, transparency degree, absorption characteristics, etc. The device can, amongst other possibilities, resemble a stick, a racket, a club, a gun, a knife, a wheel, a ring, a steering wheel, a bottle, a ball, a glass, a vase, a spoon, a fork, a cube, a dice, a figure, a puppet, a teddy, a beaker, a pedal, a switch, a glove, jewelry, a musical instrument or an auxiliary device for playing a musical instrument, such as a plectrum, a drumstick or the like. Other options are feasible.

Further, the devices according to the present invention may be used to detect and/or track objects that emit light by themselves, such as due to high temperature or further light emission processes. The light emitting part may be an exhaust stream or the like. Further, the devices according to the present invention may be used to track reflecting objects and analyze the rotation or orientation of these objects.

Further, the devices according to the present invention generally may be used in the field of building, construction and cartography. Thus, generally, one or more devices according to the present invention may be used in order to measure and/or monitor environmental areas, e.g. countryside or buildings. Therein, one or more devices according to the present invention may be combined with other methods and devices or can be used solely in order to monitor progress and accuracy of building projects, changing objects, houses, etc. The devices according to the present invention can be used for generating three-dimensional models of scanned environments, in order to construct maps of rooms, streets, houses, communities or landscapes, both

from ground or from air. Potential fields of application may be construction, cartography, real estate management, land surveying or the like. As an example, the devices according to the present invention may be used in drones or multicopters to monitor buildings, production sites, chimneys, agricultural production environments such as fields, production plants, or landscapes, to support rescue operations, to support work in dangerous environments, to support fire brigades in a burning location indoors or outdoors, or to find or monitor one or more persons or animals, or the like, or for entertainment purposes, such as a drone following and recording one or more persons doing sports such as skiing or cycling or the like, which could be realized by following a helmet, a mark, a beacon device, or the like. Devices according to the present invention could be used recognize obstacles, follow a predefined route, follow an edge, a pipe, a building, or the like, or to record a global or local map of the environment. Further, devices according to the present invention could be used for indoor or outdoor localization and positioning of drones, for stabilizing the height of a drone indoors where barometric pressure sensors are not accurate enough, or for the interaction of multiple drones such as concertized movements of several drones or recharging or refueling in the air or the like.

Further, the devices according to the present invention may be used within an interconnecting network of home appliances such as CHAIN (Cedec Home Appliances Interoperating Network) to interconnect, automate, and control basic appliance-related services in a home, e.g. energy or load management, remote diagnostics, pet related appliances, child related appliances, child surveillance, appliances related surveillance, support or service to elderly or ill persons, home security and/or surveillance, remote control of appliance operation, and automatic maintenance support. Further, the devices according to the present invention may be used in heating or cooling systems such as an air-conditioning system, to locate which part of the room should be brought to a certain temperature or humidity, especially depending on the location of one or more persons. Further, the devices according to the present invention may be used in domestic robots, such as service or autonomous robots which may be used for household chores. The devices according to the present invention may be used for a number of different purposes, such as to avoid collisions or to map the environment, but also to identify a user, to personalize the robot's performance for a given user, for security purposes, or for gesture or facial recognition. As an example, the devices according to the present invention may be used in robotic vacuum cleaners, floor-washing robots, dry-sweeping robots, ironing robots for ironing clothes, animal litter robots, such as dog or cat litter robots, charging robot for electrical vehicles, security robots that detect intruders, robotic lawn mowers, automated pool cleaners, rain gutter cleaning robots, robotic shopping carts, luggage carrying robots, line following robots, laundry robots, ironing robots, window washing robots, toy robots, patient monitoring robots, baby monitoring robots, elderly monitoring robots, children monitoring robots, transport robots, telepresence robots, professional service robots, programmable toy robots, pathfinder robots, social robots providing company to less mobile people, following robots, smart card following robots, psychotherapy robots, or robots translating speech to sign language or sign language to speech. In the context of less mobile people, such as elderly persons, household robots with the devices according to the present invention may be used for picking up objects, transporting objects, and interacting with the objects and the user in a safe way. Further, the devices according to the

present invention may be used in humanoid robots, especially in the context of using humanoid hands to pick up or hold or place objects. Further, the devices according to the present invention may be used in combination with audio interfaces especially in combination with household robots which may serve as a digital assistant with interfaces to online or offline computer applications. Further, the devices according to the present invention may be used in robots that can control switches and buttons in industrial and household purposes. Further, the devices according to the present invention may be used in smart home robots such as Mayfield's Kuri. Further the devices according to the present invention may be used in robots operating with hazardous materials or objects or in dangerous environments. As a non-limiting example, the devices according to the present invention may be used in robots or unmanned remote-controlled vehicles to operate with hazardous materials such as chemicals or radioactive materials especially after disasters, or with other hazardous or potentially hazardous objects such as mines, unexploded arms, or the like, or to operate in or to investigate insecure environments such as near burning objects or post disaster areas or for manned or unmanned rescue operations in the air, in the sea, underground, or the like.

Further, devices according to the present invention may be used for the inspection of adhesive beads, sealing beads, or the like, such as to recognize disruptions, slubs, contractions, asymmetries, local defects, or the like. Further, devices according to the present invention may be used to count objects such as dry fruits on a conveyer belt, such as in difficult situations, such as when fruit of similar color and shape may be in direct contact with each other. Further, devices according to the present invention may be used in quality control of die cast or injection molded parts such as to ensure flawless casting or molding, recognize surface damages, worn out toolings or the like. Further, devices according to the present invention may be used for laserscribing such as for quality control and positioning of the laser. Further, devices according to the present invention may be used for sorting systems, such as to detect position, rotation, and shape of an object, compare it to a database of objects, and classify the object. Further, devices according to the present invention may be used for stamping part inspection, packaging inspection, such as food and pharma packaging inspection, filament inspection, or the like.

Further, devices according to the present invention may be used for navigation purposes, where Global Positioning Systems (GPS) are not sufficiently reliable. GPS signals commonly use radio waves that are can be blocked or difficult to receive indoors or outdoors in valleys or in forests below the treeline. Further, especially in unmanned autonomous vehicles, the weight of the system may be critical. Especially unmanned autonomous vehicles need high-speed position data for reliable feedback and stability of their control systems. Using devices according to the present invention may allow short time response and positioning without adding weight due to a heavy device.

Further, the devices according to the present invention may be used in household, mobile or entertainment devices, such as a refrigerator, a microwave, a washing machine, a window blind or shutter, a household alarm, an air condition devices, a heating device, a television, an audio device, a smart watch, a mobile phone, a phone, a dishwasher, a stove or the like, to detect the

presence of a person, to monitor the contents or function of the device, or to interact with the person and/or share information about the person with further household, mobile or entertainment devices.

- 5 Further, the devices according to the present invention may be used to support elderly or disabled persons or persons with limited or no vision, such as in household chores or at work such as in devices for holding, carrying, or picking objects, or in a safety system with optical or acoustical signals signaling obstacles in the environment.
- 10 The devices according to the present invention may further be used in agriculture, for example to detect and sort out vermin, weeds, and/or infected crop plants, fully or in parts, wherein crop plants may be infected by fungus or insects. Further, for harvesting crops, the devices according to the present invention may be used to detect animals, such as deer, which may otherwise be harmed by harvesting devices. Further, the devices according to the present invention may
- 15 be used to monitor the growth of plants in a field or greenhouse, in particular to adjust the amount of water or fertilizer or crop protection products for a given region in the field or greenhouse or even for a given plant. Further, in agricultural biotechnology, the devices according to the present invention may be used to monitor the size and shape of plants.
- 20 Further, devices according to the present invention may be used to automatically remove weeds such as with mechanical means, such as to avoid the use of herbicides. Further, devices according to the present invention may be used in the field of agriculture, in particular to detect and/or locate specific insects such as to decide whether or not to apply a crop protection or fertilization substance, such as to reduce the amount of applied substance or to protect specific
- 25 groups of animals such as bees.

Further, devices according to the present invention may be used to guide users during a shaving, hair cutting, or cosmetics procedure, or the like. Further, devices according to the present invention may be used to record or monitor what is played on an instrument, such as a violin.

- 30 Further, devices according to the present invention may be used in smart household appliances such as a smart refrigerator, such as to monitor the contents of the refrigerator and transmit notifications depending on the contents. Further, devices according to the present invention may be used for monitoring or tracking populations of humans, animals, or plants, such as deer or tree populations in forests. Further, devices according to the present invention may be used
- 35 in harvesting machines, such as for harvesting crops, flowers or fruits, such as grapes, corn, hops, apples, grains, rice, strawberries, asparagus, tulips, roses, soy beans, or the like. Further, devices according to the present invention may be used to monitor the growth of plants, animals, algae, fish, or the like, such as in breeding, food production, agriculture or research applications, to control irrigation, fertilization, humidity, temperature, use of herbicides, insecticides,
- 40 fungicides, rodenticides, or the like. Further, devices according to the present invention may be used in feeding machines for animals or pets, such as for cows, pigs, cats, dogs, birds, fish, or the like. Further, devices according to the present invention may be used in animal product production processes, such as for collecting milk, eggs, fur, meat, or the like, such as in automated

milking or butchering processes. Further, devices according to the present invention may be used for automated seeding machines, or sowing machines, or planting machines such as for planting corn, garlic, trees, salad or the like. Further, devices according to the present invention may be used to assess or monitor weather phenomena, such as clouds, fog, or the like, or to
5 warn from danger of avalanches, tsunamis, gales, earthquakes, thunder storms, or the like. Further, devices according to the present invention may be used to measure motions, shocks, concussions, or the like such as to monitor earthquake risk. Further, devices according to the present invention may be used in traffic technology to monitor dangerous crossings, to control traffic lights depending on traffic, to monitor public spaces, to monitor roads, gyms, stadiums, ski
10 resorts, public events, or the like. Further, devices according to the present invention may be used in medical applications such as to monitor or analyze tissues, medical or biological assays, changes in tissues such as in moles or melanoma or the like, to count bacteria, blood cells, cells, algae, or the like, for retina scans, breath or pulse measurements, gastroscopy, patient surveillance, or the like. Further, devices according to the present invention may be used to
15 monitor the shape, size, or circumference of drops, streams, jets, or the like or to analyze, assess, or monitor profiles or gas or liquid currents such as in a wind channel, or the like. Further, devices according to the present invention may be used to warn drivers such as car or train drivers when they are getting sick or tired or the like. Further, devices according to the present invention may be used in material testing to recognize strains or tensions or fissures, or the like.
20 Further, devices according to the present invention may be used in sailing to monitor and optimize sail positions such as automatically. Further, devices according to the present invention may be used for fuel level gauges.

Further, the devices according to the present invention may be combined with sensors to detect
25 chemicals or pollutants, electronic nose chips, microbe sensor chips to detect bacteria or viruses or the like, Geiger counters, tactile sensors, heat sensors, or the like. This may for example be used in constructing smart robots which are configured for handling dangerous or difficult tasks, such as in treating highly infectious patients, handling or removing highly dangerous substances, cleaning highly polluted areas, such as highly radioactive areas or chemical spills, or
30 for pest control in agriculture.

One or more devices according to the present invention can further be used for scanning of objects, such as in combination with CAD or similar software, such as for additive manufacturing and/or 3D printing. Therein, use may be made of the high dimensional accuracy of the devices
35 according to the present invention, e.g. in x-, y- or z- direction or in any arbitrary combination of these directions, such as simultaneously. Further, the devices according to the present invention may be used in inspections and maintenance, such as pipeline inspection gauges. Further, in a production environment, the devices according to the present invention may be used to work with objects of a badly defined shape such as naturally grown objects, such as sorting
40 vegetables or other natural products by shape or size or cutting products such as meat or objects that are manufactured with a precision that is lower than the precision needed for a processing step.

Further, the devices according to the present invention may be used in local navigation systems to allow autonomously or partially autonomously moving vehicles or multicopters or the like through an indoor or outdoor space. A non-limiting example may comprise vehicles moving through an automated storage for picking up objects and placing them at a different location.

- 5 Indoor navigation may further be used in shopping malls, retail stores, museums, airports, or train stations, to track the location of mobile goods, mobile devices, baggage, customers or employees, or to supply users with a location specific information, such as the current position on a map, or information on goods sold, or the like.
- 10 Further, the devices according to the present invention may be used to ensure safe driving of motorcycles such as driving assistance for motorcycles by monitoring speed, inclination, upcoming obstacles, unevenness of the road, or curves or the like. Further, the devices according to the present invention may be used in trains or trams to avoid collisions.
- 15 Further, the devices according to the present invention may be used in handheld devices, such as for scanning packaging or parcels to optimize a logistics process. Further, the devices according to the present invention may be used in further handheld devices such as personal shopping devices, RFID-readers, handheld devices for use in hospitals or health environments such as for medical use or to obtain, exchange or record patient or patient health related information, smart badges for retail or health environments, or the like.
- 20

- As outlined above, the devices according to the present invention may further be used in manufacturing, quality control or identification applications, such as in product identification or size identification (such as for finding an optimal place or package, for reducing waste etc.). Further,
- 25 the devices according to the present invention may be used in logistics applications. Thus, the devices according to the present invention may be used for optimized loading or packing containers or vehicles. Further, devices according to the present invention may be recalibrated using bar codes, QR-codes or prerecorded symbols of known size by using the at least one image matrix and comparing the prerecorded size with a measured property of the recorded image of
- 30 the bar code, QR code or prerecorded symbol, such as by comparing the width or height of the symbol with a prerecorded value. Further, the devices according to the present invention may be used for monitoring or controlling of surface damages in the field of manufacturing, for monitoring or controlling rental objects such as rental vehicles, and/or for insurance applications, such as for assessment of damages. Further, the devices according to the present invention
- 35 may be used for identifying a size of material, object or tools, such as for optimal material handling, especially in combination with robots. Further, the devices according to the present invention may be used for process control in production, e.g. for observing filling level of tanks. Further, the devices according to the present invention may be used for maintenance of production assets like, but not limited to, tanks, pipes, reactors, tools etc. Further, the devices according to
- 40 the present invention may be used for analyzing 3D-quality marks. Further, the devices according to the present invention may be used in manufacturing tailor-made goods such as tooth inlays, dental braces, prosthesis, clothes or the like. The devices according to the present invention may also be combined with one or more 3D-printers for rapid prototyping, 3D-copying or the

like. Further, the devices according to the present invention may be used for detecting the shape of one or more articles, such as for anti-product piracy and for anti-counterfeiting purposes.

5 Thus, specifically, the present application may be applied in the field of photography. Thus, the detector may be part of a photographic device, specifically of a digital camera. Specifically, the detector may be used for 3D photography, specifically for digital 3D photography. Thus, the detector may form a digital 3D camera or may be part of a digital 3D camera. As used herein, the term photography generally refers to the technology of acquiring image information of at least
10 one object. As further used herein, a camera generally is a device adapted for performing photography. As further used herein, the term digital photography generally refers to the technology of acquiring image information of at least one object by using a plurality of light-sensitive elements adapted to generate electrical signals indicating an intensity and/or color of illumination, preferably digital electrical signals. As further used herein, the term 3D photography generally
15 refers to the technology of acquiring image information of at least one object in three spatial dimensions. Accordingly, a 3D camera is a device adapted for performing 3D photography. The camera generally may be adapted for acquiring a single image, such as a single 3D image, or may be adapted for acquiring a plurality of images, such as a sequence of images. Thus, the camera may also be a video camera adapted for video applications, such as for acquiring digital
20 video sequences.

Thus, generally, the present invention further refers to a camera, specifically a digital camera, more specifically a 3D camera or digital 3D camera, for imaging at least one object. As outlined above, the term imaging, as used herein, generally refers to acquiring image information of at
25 least one object. The camera comprises at least one detector according to the present invention. The camera, as outlined above, may be adapted for acquiring a single image or for acquiring a plurality of images, such as image sequence, preferably for acquiring digital video sequences. Thus, as an example, the camera may be or may comprise a video camera. In the latter case, the camera preferably comprises a data memory for storing the image sequence.

30 As used within the present invention, the expression "position" generally refers to at least one item of information regarding one or more of an absolute position and an orientation of one or more points of the object. Thus, specifically, the position may be determined in a coordinate system of the detector, such as in a Cartesian coordinate system. Additionally or alternatively,
35 however, other types of coordinate systems may be used, such as polar coordinate systems and/or spherical coordinate systems.

As outlined above and as will be outlined in further detail below, the present invention preferably may be applied in the field of human-machine interfaces, in the field of sports and/or in the field
40 of computer games. Thus, preferably, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat, an article of clothing, a hat, a shoe. Other embodiments are feasible.

As used herein, the object generally may be an arbitrary object, chosen from a living object and a non-living object. Thus, as an example, the at least one object may comprise one or more articles and/or one or more parts of an article. Additionally or alternatively, the object may be or may comprise one or more living beings and/or one or more parts thereof, such as one or more body parts of a human being, e.g. a user, and/or an animal.

With regard to the coordinate system for determining the position of the object, which may be a coordinate system of the detector, the detector may constitute a coordinate system in which an optical axis of the detector forms the z-axis and in which, additionally, an x-axis and a y-axis may be provided which are perpendicular to the z-axis and which are perpendicular to each other. As an example, the detector and/or a part of the detector may rest at a specific point in this coordinate system, such as at the origin of this coordinate system. In this coordinate system, a direction parallel or antiparallel to the z-axis may be regarded as a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. An arbitrary direction perpendicular to the longitudinal direction may be considered a transversal direction, and an x- and/or y-coordinate may be considered a transversal coordinate.

Alternatively, other types of coordinate systems may be used. Thus, as an example, a polar coordinate system may be used in which the optical axis forms a z-axis and in which a distance from the z-axis and a polar angle may be used as additional coordinates. Again, a direction parallel or antiparallel to the z-axis may be considered a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. Any direction perpendicular to the z-axis may be considered a transversal direction, and the polar coordinate and/or the polar angle may be considered a transversal coordinate.

The detector may be a device configured for providing at least one item of information on the position of the at least one object and/or a part thereof. Thus, the position may refer to an item of information fully describing the position of the object or a part thereof, preferably in the coordinate system of the detector, or may refer to a partial information, which only partially describes the position. The detector generally may be a device adapted for detecting light beams, such as the light beams propagating from the beacon devices towards the detector.

The evaluation device and the detector may fully or partially be integrated into a single device. Thus, generally, the evaluation device also may form part of the detector. Alternatively, the evaluation device and the detector may fully or partially be embodied as separate devices. The detector may comprise further components.

The detector may be a stationary device or a mobile device. Further, the detector may be a stand-alone device or may form part of another device, such as a computer, a vehicle or any other device. Further, the detector may be a hand-held device. Other embodiments of the detector are feasible.

The detector specifically may be used to record a light-field behind a lens or lens system of the detector, comparable to a plenoptic or light-field camera. Thus, specifically, the detector may be embodied as a light-field camera adapted for acquiring images in multiple focal planes, such as simultaneously. The term light-field, as used herein, generally refers to the spatial light propagation of light inside the detector such as inside camera. The detector according to the present invention, specifically having a stack of optical sensors, may have the capability of directly recording a light-field within the detector or camera, such as behind a lens. The plurality of sensors may record images at different distances from the lens. Using, e.g., convolution-based algorithms such as "depth from focus" or "depth from defocus", the propagation direction, focus points, and spread of the light behind the lens can be modeled. From the modeled propagation of light behind the lens, images at various distances to the lens can be extracted, the depth of field can be optimized, pictures that are in focus at various distances can be extracted, or distances of objects can be calculated. Further information may be extracted.

The use of several optical sensors further allows for correcting lens errors in an image processing step after recording the images. Optical instruments often become expensive and challenging in construction, when lens errors need to be corrected. These are especially problematic in microscopes and telescopes. In microscopes, a typical lens error is that rays of varying distance to the optical axis are distorted differently (spherical aberration). In telescopes, varying the focus may occur from differing temperatures in the atmosphere. Static errors such as spherical aberration or further errors from production may be corrected by determining the errors in a calibration step and then using a fixed image processing such as fixed set of pixels and sensor, or more involved processing techniques using light propagation information. In cases in which lens errors are strongly time-dependent, i.e. dependent on weather conditions in telescopes, the lens errors may be corrected by using the light propagation behind the lens, calculating extended depth of field images, using depth from focus techniques, and others.

The detector according to the present invention may further allow for color detection. For color detection, a plurality of optical sensors having different spectral properties may be used, and sensor signals of these optical sensors may be compared. Further, the devices according to the present invention may be used in the context of gesture recognition. In this context, gesture recognition in combination with devices according to the present invention may, in particular, be used as a human-machine interface for transmitting information via motion of a body, of body parts or of objects to a machine. Herein, the information may, preferably, be transmitted via a motion of hands or hand parts, such as fingers, in particular, by pointing at objects, applying sign language, such as for deaf people, making signs for numbers, approval, disapproval, or the like, by waving the hand, such as when asking someone to approach, to leave, or to greet a person, to press an object, to take an object, or, in the field of sports or music, in a hand or finger exercise, such as a warm-up exercise. Further, the information may be transmitted by motion of arms or legs, such as rotating, kicking, grabbing, twisting, rotating, scrolling, browsing, pushing, bending, punching, shaking, arms, legs, both arms, or both legs, or a combination of arms and legs, such as for a purpose of sports or music, such as for entertainment, exercise, or training function of a machine. Further, the information may be transmitted by motion of the

whole body or major parts thereof, such as jumping, rotating, or making complex signs, such as sign language used at airports or by traffic police in order to transmit information, such as “turn right”, “turn left”, “proceed”, “slow down”, “stop”, or “stop engines”, or by pretending to swim, to dive, to run, to shoot, or the like, or by making complex motions or body positions such as in
5 yoga, pilates, judo, karate, dancing, or ballet. Further, the information may be transmitted by using a real or mock-up device for controlling a virtual device corresponding to the mock-up device, such as using a mock-up guitar for controlling a virtual guitar function in a computer program, using a real guitar for controlling a virtual guitar function in a computer program, using
10 a real or a mock-up book for reading an e-book or moving pages or browsing through in a virtual document, using a real or mock-up pen for drawing in a computer program, or the like. Further, the transmission of the information may be coupled to a feedback to the user, such as a sound, a vibration, or a motion.

15 In the context of music and/or instruments, devices according to the present invention in combination with gesture recognition may be used for exercising purposes, control of instruments, recording of instruments, playing or recording of music via use of a mock-up instrument or by only pretending to have a instrument present such as playing air guitar, such as to avoid noise or make recordings, or, for conducting of a virtual orchestra, ensemble, band, big band, choir, or the like, for practicing, exercising, recording or entertainment purposes or the like.

20 Further, in the context of safety and surveillance, devices according to the present invention in combination with gesture recognition may be used to recognize motion profiles of persons, such as recognizing a person by the way of walking or moving the body, or to use hand signs or movements or signs or movements of body parts or the whole body as access or identification
25 control such as a personal identification sign or a personal identification movement.

Further, in the context of smart home applications or internet of things, devices according to the present invention in combination with gesture recognition may be used for central or non-central
30 control of household devices which may be part of an interconnecting network of home appliances and/or household devices, such as refrigerators, central heating, air condition, microwave ovens, ice cube makers, or water boilers, or entertainment devices, such as television sets, smart phones, game consoles, video recorders, DVD players, personal computers, laptops, tablets, or combinations thereof, or a combination of household devices and entertainment devices.

35 Further, in the context of virtual reality or of augmented reality, devices according to the present invention in combination with gesture recognition may be used to control movements or function of the virtual reality application or of the augmented reality application, such as playing or controlling a game using signs, gestures, body movements or body part movements or the like,
40 moving through a virtual world, manipulating virtual objects, practicing, exercising or playing sports, arts, crafts, music or games using virtual objects such as a ball, chess figures, go stones, instruments, tools, brushes.

Further, in the context of medicine, devices according to the present invention in combination with gesture recognition may be used to support rehabilitation training, remote diagnostics, or to monitor or survey surgery or treatment, to overlay and display medical images with positions of medical devices, or to overlay display prerecorded medical images such as from magnetic resonance tomography or x-ray or the like with images from endoscopes or ultra sound or the like that are recorded during a surgery or treatment.

Further, in the context of manufacturing and process automation, devices according to the present invention in combination with gesture recognition may be used to control, teach, or program robots, drones, unmanned autonomous vehicles, service robots, movable objects, or the like, such as for programming, controlling, manufacturing, manipulating, repairing, or teaching purposes, or for remote manipulating of objects or areas, such as for safety reasons, or for maintenance purposes.

Further, in the context of business intelligence metrics, devices according to the present invention in combination with gesture recognition may be used for people counting, surveying customer movements, areas where customers spend time, objects, customers test, take, probe, or the like.

Further, devices according to the present invention may be used in the context of do-it-yourself or professional tools, especially electric or motor driven tools or power tools, such as drilling machines, saws, chisels, hammers, wrenches, staple guns, disc cutters, metals shears and nibblers, angle grinders, die grinders, drills, hammer drills, heat guns, wrenches, sanders, engravers, nailers, jig saws, biscuit joiners, wood routers, planers, polishers, tile cutters, washers, rollers, wall chasers, lathes, impact drivers, jointers, paint rollers, spray guns, morticers, or welders, in particular, to support precision in manufacturing, keeping a minimum or maximum distance, or for safety measures.

Further, the devices according to the present invention may be used to aid visually impaired persons. Further, devices according to the present invention may be used in touch screen such as to avoid direct contact such as for hygienic reasons, which may be used in retail environments, in medical applications, in production environments, or the like. Further, devices according to the present invention may be used in agricultural production environments such as in stable cleaning robots, egg collecting machines, milking machines, harvesting machines, farm machinery, harvesters, forwarders, combine harvesters, tractors, cultivators, ploughs, destoners, harrows, strip tills, broadcast seeders, planters such as potato planters, manure spreaders, sprayers, sprinkler systems, swathers, balers, loaders, forklifts, mowers, or the like.

Further, devices according to the present invention may be used for selection and/or adaption of clothing, shoes, glasses, hats, prosthesis, dental braces, for persons or animals with limited communication skills or possibilities, such as children or impaired persons, or the like. Further, devices according to the present invention may be used in the context of warehouses, logistics, distribution, shipping, loading, unloading, smart manufacturing, industry 4.0, or the like. Further,

in a manufacturing context, devices according to the present invention may be used in the context of processing, dispensing, bending, material handling, or the like.

5 The evaluation device may be or may comprise one or more integrated circuits, such as one or more application-specific integrated circuits (ASICs), and/or one or more data processing devices, such as one or more computers, preferably one or more microcomputers and/or microcontrollers, Field Programmable Arrays, or Digital Signal Processors. Additional components may be comprised, such as one or more preprocessing devices and/or data acquisition devices, such as one or more devices for receiving and/or preprocessing of the sensor signals, such as
10 one or more AD-converters and/or one or more filters. Further, the evaluation device may comprise one or more measurement devices, such as one or more measurement devices for measuring electrical currents and/or electrical voltages. Further, the evaluation device may comprise one or more data storage devices. Further, the evaluation device may comprise one or more interfaces, such as one or more wireless interfaces and/or one or more wire-bound interfaces.

15 The at least one evaluation device may be adapted to perform at least one computer program, such as at least one computer program adapted for performing or supporting one or more or even all of the method steps of the method according to the present invention. As an example, one or more algorithms may be implemented which, by using the sensor signals as input variables, may determine the position of the object.
20

The evaluation device can be connected to or may comprise at least one further data processing device that may be used for one or more of displaying, visualizing, analyzing, distributing, communicating or further processing of information, such as information obtained by the
25 optical sensor and/or by the evaluation device. The data processing device, as an example, may be connected or incorporate at least one of a display, a projector, a monitor, an LCD, a TFT, a loudspeaker, a multichannel sound system, an LED pattern, or a further visualization device. It may further be connected or incorporate at least one of a communication device or communication interface, a connector or a port, capable of sending encrypted or unencrypted
30 information using one or more of email, text messages, telephone, Bluetooth, Wi-Fi, infrared or internet interfaces, ports or connections. It may further be connected to or incorporate at least one of a processor, a graphics processor, a CPU, an Open Multimedia Applications Platform (OMAP™), an integrated circuit, a system on a chip such as products from the Apple A series or the Samsung S3C2 series, a microcontroller or microprocessor, one or more memory blocks
35 such as ROM, RAM, EEPROM, or flash memory, timing sources such as oscillators or phase-locked loops, counter-timers, real-time timers, or power-on reset generators, voltage regulators, power management circuits, or DMA controllers. Individual units may further be connected by buses such as AMBA buses or be integrated in an Internet of Things or Industry 4.0 type network.

40 The evaluation device and/or the data processing device may be connected by or have further external interfaces or ports such as one or more of serial or parallel interfaces or ports, USB, Centronics Port, FireWire, HDMI, Ethernet, Bluetooth, RFID, Wi-Fi, USART, or SPI, or analogue

interfaces or ports such as one or more of ADCs or DACs, or standardized interfaces or ports to further devices such as a 2D-camera device using an RGB-interface such as CameraLink. The evaluation device and/or the data processing device may further be connected by one or more of interprocessor interfaces or ports, FPGA-FPGA-interfaces, or serial or parallel interfaces
5 ports. The evaluation device and the data processing device may further be connected to one or more of an optical disc drive, a CD-RW drive, a DVD+RW drive, a flash drive, a memory card, a disk drive, a hard disk drive, a solid state disk or a solid state hard disk.

The evaluation device and/or the data processing device may be connected by or have one or
10 more further external connectors such as one or more of phone connectors, RCA connectors, VGA connectors, hermaphrodite connectors, USB connectors, HDMI connectors, 8P8C connectors, BCN connectors, IEC 60320 C14 connectors, optical fiber connectors, D-subminiature connectors, RF connectors, coaxial connectors, SCART connectors, XLR connectors, and/or may incorporate at least one suitable socket for one or more of these connectors.

Possible embodiments of a single device incorporating one or more of the detectors according to the present invention, the evaluation device or the data processing device, such as incorporating one or more of the optical sensor, optical systems, evaluation device, communication
15 device, data processing device, interfaces, system on a chip, display devices, or further electronic devices, are: mobile phones, personal computers, tablet PCs, televisions, game consoles or further entertainment devices. In a further embodiment, the 3D-camera functionality which will be outlined in further detail below may be integrated in devices that are available with conventional 2D-digital cameras, without a noticeable difference in the housing or appearance of the device, where the noticeable difference for the user may only be the functionality of obtaining
20 and or processing 3D information. Further, devices according to the present invention may be used in 360° digital cameras or surround view cameras.

Specifically, an embodiment incorporating the detector and/or a part thereof such as the evaluation device and/or the data processing device may be: a mobile phone incorporating a display
30 device, a data processing device, the optical sensor, optionally the sensor optics, and the evaluation device, for the functionality of a 3D camera. The detector according to the present invention specifically may be suitable for integration in entertainment devices and/or communication devices such as a mobile phone.

A further embodiment of the present invention may be an incorporation of the detector or a part thereof such as the evaluation device and/or the data processing device in a device for use in automotive, for use in autonomous driving or for use in car safety systems such as Daimler's Intelligent Drive system, wherein, as an example, a device incorporating one or more of the optical sensors, optionally one or more optical systems, the evaluation device, optionally a communication device, optionally a data processing device, optionally one or more interfaces, optionally a system on a chip, optionally one or more display devices, or optionally further electronic devices may be part of a vehicle, a car, a truck, a train, a bicycle, an airplane, a ship, a motorcycle. In automotive applications, the integration of the device into the automotive design
40

may necessitate the integration of the optical sensor, optionally optics, or device at minimal visibility from the exterior or interior. The detector or a part thereof such as the evaluation device and/or the data processing device may be especially suitable for such integration into automotive design.

5

As used herein, the term light generally refers to electromagnetic radiation in one or more of the visible spectral range, the ultraviolet spectral range and the infrared spectral range. Therein, the term visible spectral range generally refers to a spectral range of 380 nm to 780 nm. The term infrared spectral range generally refers to electromagnetic radiation in the range of 780 nm to 1 mm, preferably in the range of 780 nm to 3.0 micrometers. The term ultraviolet spectral range generally refers to electromagnetic radiation in the range of 1 nm to 380 nm, preferably in the range of 100 nm to 380 nm. Preferably, light as used within the present invention is visible light, i.e. light in the visible spectral range.

10

15

The term light beam generally may refer to an amount of light emitted and/or reflected into a specific direction. Thus, the light beam may be a bundle of the light rays having a predetermined extension in a direction perpendicular to a direction of propagation of the light beam. Preferably, the light beams may be or may comprise one or more Gaussian light beams such as a linear combination of Gaussian light beams, which may be characterized by one or more Gaussian beam parameters, such as one or more of a beam waist, a Rayleigh-length or any other beam parameter or combination of beam parameters suited to characterize a development of a beam diameter and/or a beam propagation in space.

20

25

The detector according to the present invention may further be combined with one or more other types of sensors or detectors. Thus, the detector may further comprise at least one additional detector. The at least one additional detector may be adapted for detecting at least one parameter, such as at least one of: a parameter of a surrounding environment, such as a temperature and/or a brightness of a surrounding environment; a parameter regarding a position and/or orientation of the detector; a parameter specifying a state of the object to be detected, such as a position of the object, e.g. an absolute position of the object and/or an orientation of the object in space. Thus, generally, the principles of the present invention may be combined with other measurement principles in order to gain additional information and/or in order to verify measurement results or reduce measurement errors or noise.

30

35

The human-machine interface may comprise a plurality of beacon devices which are adapted to be at least one of directly or indirectly attached to the user and held by the user. Thus, the beacon devices each may independently be attached to the user by any suitable means, such as by an appropriate fixing device. Additionally or alternatively, the user may hold and/or carry the at least one beacon device or one or more of the beacon devices in his or her hands and/or by wearing the at least one beacon device and/or a garment containing the beacon device on a body part.

40

The beacon device generally may be an arbitrary device which may be detected by the at least one detector and/or which facilitates detection by the at least one detector. Thus, as outlined above or as will be outlined in further detail below, the beacon device may be an active beacon device adapted for generating the at least one light beam to be detected by the detector, such as by having one or more illumination sources for generating the at least one light beam. Additionally or alternatively, the beacon device may fully or partially be designed as a passive beacon device, such as by providing one or more reflective elements adapted to reflect a light beam generated by a separate illumination source. The at least one beacon device may permanently or temporarily be attached to the user in a direct or indirect way and/or may be carried or held by the user. The attachment may take place by using one or more attachment means and/or by the user himself or herself, such as by the user holding the at least one beacon device by hand and/or by the user wearing the beacon device.

Additionally or alternatively, the beacon devices may be at least one of attached to an object and integrated into an object held by the user, which, in the sense of the present invention, shall be included into the meaning of the option of the user holding the beacon devices. Thus, as will be outlined in further detail below, the beacon devices may be attached to or integrated into a control element which may be part of the human-machine interface and which may be held or carried by the user, and of which the orientation may be recognized by the detector device. Thus, generally, the present invention also refers to a detector system comprising at least one detector device according to the present invention and which, further, may comprise at least one object, wherein the beacon devices are one of attached to the object, held by the object and integrated into the object. As an example, the object preferably may form a control element, the orientation of which may be recognized by a user. Thus, the detector system may be part of the human-machine interface as outlined above or as outlined in further detail below. As an example, the user may handle the control element in a specific way in order to transmit one or more items of information to a machine, such as in order to transmit one or more commands to the machine.

Alternatively, the detector system may be used in other ways. Thus, as an example, the object of the detector system may be different from a user or a body part of the user and, as an example, may be an object which moves independently from the user. As an example, the detector system may be used for controlling apparatuses and/or industrial processes, such as manufacturing processes and/or robotics processes. Thus, as an example, the object may be a machine and/or a machine part, such as a robot arm, the orientation of which may be detected by using the detector system.

The human-machine interface may be adapted in such a way that the detector device generates at least one item of information on the position of the user or of at least one body part of the user. Specifically in case a manner of attachment of the at least one beacon device to the user is known, by evaluating the position of the at least one beacon device, at least one item of information on a position and/or an orientation of the user or of a body part of the user may be gained.

The beacon device preferably is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user. As outlined above, the beacon device may fully or partially be designed as an active beacon device. Thus, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be transmitted to the detector, preferably at least one light beam having known beam properties. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

The object, which may form part of the detector system, may generally have an arbitrary shape. Preferably, the object being part of the detector system, as outlined above, may be a control element which may be handled by a user, such as manually. As an example, the control element may be or may comprise at least one element selected from the group consisting of: a glove, a jacket, a hat, shoes, trousers and a suit, a stick that may be held by hand, a bat, a club, a racket, a cane, a toy, such as a toy gun. Thus, as an example, the detector system may be part of the human-machine interface and/or of the entertainment device.

As used herein, an entertainment device is a device which may serve the purpose of leisure and/or entertainment of one or more users, in the following also referred to as one or more players. As an example, the entertainment device may serve the purpose of gaming, preferably computer gaming. Thus, the entertainment device may be implemented into a computer, a computer network or a computer system or may comprise a computer, a computer network or a computer system which runs one or more gaming software programs.

The entertainment device comprises at least one human-machine interface according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed below. The entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface. The at least one item of information may be transmitted to and/or may be used by a controller and/or a computer of the entertainment device. The at least one item of information preferably may comprise at least one command adapted for influencing the course of a game. Thus, as an example, the at least one item of information may include at least one item of information on at least one orientation of the player and/or of one or more body parts of the player, thereby allowing for the player to simulate a specific position and/or orientation and/or action required for gaming. As an example, one or more of the following movements may be simulated and communicated to a controller and/or a computer of the entertainment device: dancing; running; jumping; swinging of a racket; swinging of a bat; swinging of a club; pointing of an object towards another object, such as pointing of a toy gun towards a target.

The entertainment device as a part or as a whole, preferably a controller and/or a computer of the entertainment device, is designed to vary the entertainment function in accordance with the information. Thus, as outlined above, a course of a game might be influenced in accordance

with the at least one item of information. Thus, the entertainment device might include one or more controllers which might be separate from the evaluation device of the at least one detector and/or which might be fully or partially identical to the at least one evaluation device or which might even include the at least one evaluation device. Preferably, the at least one controller
5 might include one or more data processing devices, such as one or more computers and/or microcontrollers.

As further used herein, a tracking system is a device which is adapted to gather information on a series of past positions of the at least one object and/or at least one part of the object. Additionally,
10 the tracking system may be adapted to provide information on at least one predicted future position and/or orientation of the at least one object or the at least one part of the object. The tracking system may have at least one track controller, which may fully or partially be embodied as an electronic device, preferably as at least one data processing device, more preferably as at least one computer or microcontroller. Again, the at least one track controller may
15 fully or partially comprise the at least one evaluation device and/or may be part of the at least one evaluation device and/or may fully or partially be identical to the at least one evaluation device.

The tracking system comprises at least one detector according to the present invention, such as
20 at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time, such as by recording groups of data or data pairs, each group of data or data pair comprising at least one position information and at least one time infor-
25 mation.

The tracking system may further comprise the at least one detector system according to the present invention. Thus, besides the at least one detector and the at least one evaluation device and the optional at least one beacon device, the tracking system may further comprise the ob-
30 ject itself or a part of the object, such as at least one control element comprising the beacon devices or at least one beacon device, wherein the control element is directly or indirectly attachable to or integratable into the object to be tracked.

The tracking system may be adapted to initiate one or more actions of the tracking system itself and/or of one or more separate devices. For the latter purpose, the tracking system, preferably the track controller, may have one or more wireless and/or wire-bound interfaces and/or other types of control connections for initiating at least one action. Preferably, the at least one track controller may be adapted to initiate at least one action in accordance with at least one actual position of the object. As an example, the action may be selected from the group consisting of:
35 a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.
40

As an example of application of a tracking system, the tracking system may be used for continuously pointing at least one first object to at least one second object even though the first object and/or the second object might move. Potential examples, again, may be found in industrial applications, such as in robotics and/or for continuously working on an article even though the article is moving, such as during manufacturing in a manufacturing line or assembly line. Additionally or alternatively, the tracking system might be used for illumination purposes, such as for continuously illuminating the object by continuously pointing an illumination source to the object even though the object might be moving. Further applications might be found in communication systems, such as in order to continuously transmit information to a moving object by pointing a transmitter towards the moving object.

The proposed devices and methods provide a large number of advantages over known detectors of this kind. Thus, the detector generally may avoid the shortcomings of the known prior art systems disclosed above. Specifically, the detector may avoid the use of FiP sensors, thereby allowing for e.g. using simple and cheap and commercially available semiconductor sensors such as silicon photodiodes. These photodiodes generally do not show a luminance dependency, and the method disclosed above is generally independent from the brightness of the scenery and/or the brightness of the light spot on the light beam. Consequently, a range of measurement in terms of luminance or total power of the light beam entering the detector is generally larger in the present invention as compared to many of the devices disclosed above. Further, the measurement by using the detector according to the present invention is generally independent from the target spot size, i.e. from either the size of the object, the size of a light spot projected onto the object or the size of a beacon device being one or more of attached to the object, integrated into the object or held by the object.

The detector according to the present invention may be realized as a simple device combining the functionality of distance measurement or measurement of z-coordinates, with the additional option of measuring one or more transversal coordinates, thereby integrating the functionality of a PSD.

The result of the measurement, i.e. the position determined by the detector such as the at least one longitudinal coordinate, may be rendered widely independent from the brightness of the scenery and/or the brightness of the object, the brightness of the at least one beacon device, the brightness of the at least one illumination source or the total power of the light beam propagating from the object to the detector. Further, due to this independence and wide range of measurement in terms of brightness, reflective objects or non-reflective objects may be used.

When mentioning a range of measurement, the range of measurement may both refer to a range of brightness which may be used with the detector according to the present invention, such as a range of total powers of the light beam, or may refer to a range of distances between the detector and the object which may be measured. Conventional detectors, such as according to one or more of the documents listed above, are typically limited in both ranges of measurement. The use of the quotient signal, as mentioned above, contrarily, provides a wide range of

continuously and monotonously decreasing or increasing functions which may be used to determine the longitudinal coordinate from the quotient signal. Consequently, a very wide range of measurement in terms of distance between the object and the detector is given. Similarly, due to the general independence of the quotient signal from the total power of the light beam, at least as long as no saturation of one or both of the optical sensors is reached, this also provides a very wide range of measurement in terms of brightness, i.e. in terms of total power of the light beam.

The light beam, within the detector, generally may propagate along an optical axis of the detector. The light beam, however, may also propagate in other ways than along the optical axis. As an example, an illumination light beam may be generated which propagates along the optical axis or which propagates parallel to the optical axis or at an angle to the optical axis which is different from 0° , such as an angle of 1° to 20° . Other embodiments are feasible.

Overall, in the context of the present invention, the following embodiments are regarded as preferred:

Embodiment 1: A detector for determining a position of at least one object, the detector comprising

- at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by a reflection light beam propagating from the object to the detector, wherein the sensor element is adapted to determine at least one reflection image;
- at least one evaluation device, wherein the evaluation device is adapted to select at least one reflection feature of the reflection image, wherein the evaluation device is configured for determining at least one longitudinal region of the selected reflection feature of the reflection image by evaluating a combined signal Q from the sensor signals, wherein the evaluation device is adapted to determine at least one displacement region in at least one reference image corresponding to the longitudinal region, wherein the evaluation device is adapted to match the selected reflection feature with at least one reference feature within the displacement region.

Embodiment 2: The detector according to the preceding embodiment, wherein the evaluation device is adapted to determine a displacement of the matched reference feature and the selected reflection feature, wherein the evaluation device is adapted to determine a longitudinal information of the matched feature using a predetermined relationship between a longitudinal coordinate and the displacement.

Embodiment 3: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

Embodiment 4: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for using at least one predetermined relationship between the combined signal Q and the longitudinal region for determining the longitudinal region.

Embodiment 5: The detector according to any one of the preceding embodiments, wherein the evaluation device is adapted to determine at least one longitudinal coordinate z of the selected reflection feature by evaluating the combined signal Q , wherein the longitudinal region is given by the longitudinal coordinate z and an error interval $\pm\epsilon$.

Embodiment 6: The detector according to the preceding embodiment, wherein the reference image and the reflection image are images of the object determined at different spatial positions having a fixed distance, wherein the evaluation device is adapted to determine an epipolar line in the reference image.

Embodiment 7: The detector according to the preceding embodiment, wherein the displacement region extends along the epipolar line, wherein the evaluation device is adapted to determine the reference feature along the epipolar line corresponding to the longitudinal coordinate z and to determine an extent of the displacement region along the epipolar line corresponding to the error interval $\pm\epsilon$.

Embodiment 8: The detector according to the preceding embodiment, wherein the evaluation device is configured to perform the following steps:

- Determining the displacement region for the image position of each reflection feature;
- Assigning an epipolar line to the displacement region of each reflection feature such as by assigning the epipolar line closest to a displacement region and/or within a displacement region and/or closest to a displacement region along a direction orthogonal to the epipolar line;
- Assigning and/or determining at least one reference feature to each reflection feature such as by assigning the reference feature closest to the assigned displacement region and/or within the assigned displacement region and/or closest to the assigned displacement region along the assigned epipolar line and/or within the assigned displacement region along the assigned epipolar line.

Embodiment 9: The detector according to any one of the preceding embodiments, wherein the evaluation device is adapted to match the selected feature of the reflection image with the reference feature within the displacement region by using at least one evaluation algorithm considering the determined longitudinal coordinate z .

Embodiment 10: The detector according to the preceding embodiments, wherein the evaluation algorithm is a linear scaling algorithm.

Embodiment 11: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A1 and A2 are different areas of at least one beam profile of the reflection light beam at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o.

Embodiment 12: The detector according to the preceding embodiment, wherein each of the sensor signals comprises at least one information of at least one area of the beam profile of the reflection light beam.

Embodiment 13: The detector according to any of the two preceding embodiments, wherein the beam profile is selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles.

Embodiment 14: The detector according to any one of the three preceding embodiments, wherein the light sensitive areas are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.

Embodiment 15: The detector according to the preceding embodiment, wherein the evaluation device is configured to determine the first area of the beam profile and the second area of the beam profile.

Embodiment 16: The detector according to any one of the two preceding embodiments, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile.

Embodiment 17: The detector according to any one of the two preceding embodiments, wherein the beam profile is segmented by a secant or chord passing the center of the beam profile by a given distance, whereas the first segment comprises the center information, whereas the second segment comprises essentially edge information.

Embodiment 18: The detector according to the preceding embodiment, wherein the edge information comprises information relating to a number of photons in the first area of the beam profile and the center information comprises information relating to a number of photons in the second area of the beam profile.

Embodiment 19: The detector according to any one of the two preceding embodiments, wherein the evaluation device is configured to derive the combined signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information.

Embodiment 20: The detector according to any one of the preceding embodiments, wherein the at least one evaluation device is configured for evaluating the sensor signals, by

- a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
- b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;
- c) determining at least one combined signal by combining the center signal and the sum signal; and
- d) determining the longitudinal region by evaluating the combined signal.

Embodiment 21: The detector according to the preceding embodiment, wherein the center signal is selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

Embodiment 22: The detector according to any one of the two preceding embodiments, wherein the sum signal is selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; an integral of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor

signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal.

5 Embodiment 23: The detector according to any one of the three preceding embodiments, wherein the combined signal is a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa.

10 Embodiment 24: The detector according to any one of the preceding embodiment, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the quotient signal.

15 Embodiment 25: The detector according to any one of the preceding embodiments, wherein the detector comprises at least one optical element, wherein the optical element is at least one element selected from the group consisting of: transfer device, such as at least one lens and/or at least one lens system, at least one diffractive optical element.

20 Embodiment 26: The detector according to any one of the six preceding embodiments, wherein the evaluation device is further configured for determining at least one transversal coordinate of the object by evaluating a transversal position of the at least one optical sensor having the highest sensor signal.

25 Embodiment 27: The detector according to any one of the preceding embodiments, wherein the sensor element comprises at least one CMOS sensor.

Embodiment 28: The detector according to any one of the preceding embodiments, wherein the detector comprises at least one illumination source, wherein the illumination source is adapted to generate at least one illumination pattern for illumination of the object.

30 Embodiment 29: The detector according to preceding embodiment, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern or a random point pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern, in particular a rotated hexagonal pattern and/or a displaced hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines.

40 Embodiment 30: The detector according to any one of the two preceding embodiments, wherein the sensor element is adapted to determine at least one reflection pattern, wherein the evaluation device is adapted to select at least one feature of the reflection pattern and to determine the

longitudinal region of the selected feature of the reflection pattern by evaluating the combined signal Q from the sensor signals.

5 Embodiment 31: The detector according to the preceding embodiment, wherein the reference image is an image of the illumination pattern at an image plane at a position of the illumination source, wherein the evaluation device is adapted to determine the displacement region in the reference image corresponding to the longitudinal region of the selected feature of the reflection pattern, wherein the evaluation device is adapted to match the selected feature of the reflection pattern with at least one feature of the reference pattern within the displacement region.

10

Embodiment 32: The detector according to any one of the four preceding embodiments, wherein the illumination source and the sensor element are separated by a fixed distance.

15 Embodiment 33: The detector according to any one of the five preceding embodiments, wherein the detector comprises at least two sensor elements each having a matrix of optical sensors.

20 Embodiment 34: The detector according to the preceding embodiment, where at least one first sensor element and at least one second sensor element are positioned at different spatial positions, wherein a relative distance between the first sensor element and the second element is fixed.

25 Embodiment 35: The detector according to any one of the two preceding embodiments, wherein the at least one first sensor element is adapted to determine at least one first reflection pattern and the at least one second sensor element is adapted to determine at least one second reflection pattern, wherein the evaluation device is adapted to select at least one image determined by the first sensor element or the second sensor element as reflection image and to select at least one image determined by the other one of the first sensor element or the second sensor element as reference image.

30 Embodiment 36: A detector system for determining a position of at least one object, the detector system comprising at least one detector according to any one of the preceding embodiments, the detector system further comprising at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object.

35

40 Embodiment 37: A human-machine interface for exchanging at least one item of information between a user and a machine, wherein the human-machine interface comprises at least one detector system according to the preceding embodiment, wherein the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user and held by the user, wherein the human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to assign to the position at least one item of information.

Embodiment 38: An entertainment device for carrying out at least one entertainment function, wherein the entertainment device comprises at least one human-machine interface according to the preceding embodiment, wherein the entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface, wherein
5 the entertainment device is designed to vary the entertainment function in accordance with the information.

Embodiment 39: A tracking system for tracking a position of at least one movable object, the tracking system comprising at least one detector system according to any one of the preceding
10 embodiments referring to a detector system, the tracking system further comprising at least one track controller, wherein the track controller is adapted to track a series of positions of the object at specific points in time.

Embodiment 40: A scanning system for determining a depth profile of a scenery, the scanning
15 system comprising at least one detector according to any of the preceding embodiments referring to a detector, the scanning system further comprising at least one illumination source adapted to scan the scenery with at least one light beam.

Embodiment 41: A camera for imaging at least one object, the camera comprising at least one
20 detector according to any one of the preceding embodiments referring to a detector.

Embodiment 42: A method for determining a position of at least one object by using at least one detector according to any one of the preceding embodiments referring to a detector, the method comprising the following steps:

- 25 - generating at least two sensor signals in response to an illumination of at least one sensor element having a matrix of optical sensors by at least one reflection light beam propagating from the object to the detector, the optical sensors each having a light-sensitive area;
- determining at least one reflection image by using the sensor element;
- 30 - selecting at least one reflection feature of the reflection image and evaluating the sensor signals by using at least one evaluation device, thereby, determining at least one longitudinal region of the selected reflection feature, wherein the evaluating comprises evaluating a combined signal Q from the sensor signals;
- determining at least one displacement region in at least one reference image corresponding to the longitudinal region;
- 35 - matching the selected reflection feature with at least one reference feature within the displacement region.

Embodiment 43: The method according to the preceding embodiment, wherein a displacement
40 of the matched reference feature and the selected reflection feature is determined, wherein a longitudinal information of the matched feature is determined using a predetermined relationship between a longitudinal coordinate and the displacement.

Embodiment 44: The method according to any one of the preceding embodiments referring to a method, wherein the deriving of the combined signal Q comprises one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

5

Embodiment 45: A use of the detector according to any one of the preceding embodiments relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a logistics application; an outdoor application; a mobile application; a communication application; a tracking application; a photography application; a machine vision application; a robotics application; a quality control application; a manufacturing application.

10

Brief description of the figures

15

Further optional details and features of the invention are evident from the description of preferred exemplary embodiments which follows in conjunction with the dependent claims. In this context, the particular features may be implemented in an isolated fashion or in combination with other features. The invention is not restricted to the exemplary embodiments. The exemplary

embodiments are shown schematically in the figures. Identical reference numerals in the individual figures refer to identical elements or elements with identical function, or elements which correspond to one another with regard to their functions.

20

Specifically, in the figures:

25

Figure 1 shows a first embodiment of a detector according to the present invention;

30

Figure 2 shows a further embodiment of the detector according to the present invention;

Figure 3 shows an embodiment of a detector system, camera, entertainment device, tracking system;

35

Figure 4 shows an embodiment of determining a longitudinal coordinate z using a line pattern;

Figures 5A to C show three embodiments of a hexagonal illumination pattern; and

40

Figure 6 shows an embodiment of a scanning system.

Detailed description of the embodiments:

Fig. 1 shows in a highly schematic fashion a first embodiment of a detector 110 for determining a position of at least one object 112. The detector 110 comprises at least one sensor element 116 having a matrix 118 of optical sensors 120. The optical sensors 120 each have a light-sensitive area 122.

The sensor element 116 may be formed as a unitary, single device or as a combination of several devices. The matrix 118 specifically may be or may comprise a rectangular matrix having one or more rows and one or more columns. The rows and columns specifically may be arranged in a rectangular fashion. However, other arrangements are feasible, such as nonrectangular arrangements. As an example, circular arrangements are also feasible, wherein the elements are arranged in concentric circles or ellipses about a center point. For example, the matrix 118 may be a single row of pixels. Other arrangements are feasible.

The optical sensors 120 of the matrix 118 specifically may be equal in one or more of size, sensitivity and other optical, electrical and mechanical properties. The light-sensitive areas 122 of all optical sensors 120 of the matrix 118 specifically may be located in a common plane, the common plane preferably facing the object 112, such that a light beam propagating from the object to the detector 110 may generate a light spot on the common plane. The light-sensitive area 122 may specifically be located on a surface of the respective optical sensor 120. Other embodiments, however, are feasible. The optical sensors 120 may comprise for example, at least one CCD and/or CMOS device. As an example, the optical sensors 120 may be part of or constitute a pixelated optical device. As an example, the optical sensors may be part of or constitute at least one CCD and/or CMOS device having a matrix of pixels, each pixel forming a light-sensitive area 122.

The optical sensors 120 specifically may be or may comprise photodetectors, preferably inorganic photodetectors, more preferably inorganic semiconductor photodetectors, most preferably silicon photodetectors. Specifically, the optical sensors 120 may be sensitive in the infrared spectral range. All of the optical sensors 120 of the matrix 118 or at least a group of the optical sensors 120 of the matrix 118 specifically may be identical. Groups of identical optical sensors 120 of the matrix 118 specifically may be provided for different spectral ranges, or all optical sensors may be identical in terms of spectral sensitivity. Further, the optical sensors 120 may be identical in size and/or with regard to their electronic or optoelectronic properties. The matrix 118 may be composed of independent optical sensors 120. Thus, a matrix 118 of inorganic photodiodes may be composed. Alternatively, however, a commercially available matrix may be used, such as one or more of a CCD detector, such as a CCD detector chip, and/or a CMOS detector, such as a CMOS detector chip.

The optical sensors 120 may form a sensor array or may be part of a sensor array, such as the above-mentioned matrix. Thus, as an example, the detector 110 may comprise an array of optical sensors 120, such as a rectangular array, having m rows and n columns, with m, n, independently, being positive integers. Preferably, more than one column and more than one row is

given, i.e. $n > 1$, $m > 1$. Thus, as an example, n may be 2 to 16 or higher and m may be 2 to 16 or higher. Preferably, the ratio of the number of rows and the number of columns is close to 1. As an example, n and m may be selected such that $0.3 \leq m/n \leq 3$, such as by choosing $m/n = 1:1$, 4:3, 16:9 or similar. As an example, the array may be a square array, having an equal number of rows and columns, such as by choosing $m=2$, $n=2$ or $m=3$, $n=3$ or the like.

The matrix 118 specifically may be a rectangular matrix having at least one row, preferably a plurality of rows, and a plurality of columns. As an example, the rows and columns may be oriented essentially perpendicular. In order to provide a wide range of view, the matrix 118 specifically may have at least 10 rows, preferably at least 50 rows, more preferably at least 100 rows. Similarly, the matrix may have at least 10 columns, preferably at least 50 columns, more preferably at least 100 columns. The matrix 118 may comprise at least 50 optical sensors 120, preferably at least 100 optical sensors 120, more preferably at least 500 optical sensors 120. The matrix 118 may comprise a number of pixels in a multi-mega pixel range. Other embodiments, however, are feasible.

In the embodiment shown in Figure 1, the detector 110 further comprises an illumination source 124. As an example, the illumination source 124 may be configured for generating an illuminating light beam for illuminating the object 112. The detector 110 may be configured such that the illuminating light beam propagates from the detector 110 towards the object 112 along an optical axis of the detector 110. For this purpose, the detector 110 may comprise at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

The illumination source 124 may be adapted to generate at least one illumination pattern for illumination of the object 112. Specifically, the illumination source 124 may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The pattern may comprise a plurality of features. The pattern may comprise an arrangement of periodic or non-periodic features. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern; at least one pattern comprising at least one pre-known feature. For example, the illumination source 124 may be adapted to generate and/or to project a cloud of points. The illumination source 124 may comprise one or more of at least one light projector; at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The illumination source 124 may comprise at least one light source adapted to generate the illumination pattern directly. The illumination source 124 may comprise the at least one light projector adapted to generate a cloud of points such that the illumination pattern may comprise a plurality of point pattern. The illumination source 124 may comprise at least one mask adapted to generate the illumination pattern from at least one light beam generated by the illumination source 124.

In the embodiment shown in Figure 1, the illumination source 124 may illuminate the at least one object 112 with the illumination pattern. The illumination pattern may comprise a plurality of points as image features. These points are illustrated as light beams 115 emerging from the illumination source 124.

5

Each optical sensor 120 is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area 122 by a reflection light beam propagating from the object 112 to the detector 110.

10 Furthermore, the sensor element 116 is adapted to determine at least one reflection image 126. The matrix 118 may comprise the reflection image 126. The reflection image 126 may comprise points as reflection features. These points result from reflection light beams 125 originating from the at least one object 112. Crossings 131 of the illumination light beams and the reflection light beams 125 correspond to possible positions 114 of the at least one object 112.

15

The detector 127 may comprise at least one transfer device 127 comprising one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam de-
20 flection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system. In particular, the transfer device 127 may comprise at least one collimating lens adapted to focus at least one object point in an image plane.

25 The detector 110 comprises at least one evaluation device 128. The evaluation device 126 is adapted to select at least one reflection feature of the reflection image 126, for example selected reflection feature 129. The evaluation device 128 may be adapted to perform at least one image analysis and/or image processing in order to identify the reflection feature. The image analysis and/or image processing may use at least one feature detection algorithm. The image
30 analysis and/or image processing may comprise one or more of the following: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency de-
35 composition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a blob analysis; applying an edge filter; applying a low-pass filter; applying a Fourier transformation; apply-
40 ing a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be deter-

mined manually by a user or may be determined automatically, such as by recognizing an object within an image generated by the optical sensors.

If the selected reflection feature 129 is matched to a corresponding reference feature, the corresponding light beams are matched and the distance of the object 112 can be calculated. For a selected reflection feature 129 and a corresponding reflection light beam, the number of corresponding illumination light beams, and thus the number of corresponding reference features 112, is reduced after determining a combined signal Q.

- 5 The evaluation device 128 is configured for determining at least one longitudinal region 130 of the selected reflection feature 129 of the reflection image by evaluating the combined signal Q from the sensor signals. The evaluation device 128 may be adapted to determine at least one longitudinal coordinate z of the selected reflection feature 129 by evaluating the combined signal Q, wherein the longitudinal region is given by the longitudinal coordinate z and an error interval $\pm \varepsilon$. Error ε may depend on measurement uncertainty of the optical sensor. For example, the error interval may be $\pm 10\%$, preferably $\pm 5\%$, more preferably $\pm 1\%$. The evaluation device 128 may be configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals. The evaluation device 128 may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal region for determining the longitudinal region. For example, the evaluation device 128 may be configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

- wherein x and y are transversal coordinates, A1 and A2 are different areas of at least one beam profile of the reflection light beam at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o. Area A1 and area A2 may differ. In particular, A1 and A2 are not congruent. Thus, A1 and A2 may differ in one or more of the shape or content. The beam profile may be a transverse intensity profile of the light beam. The beam profile may be a cross section of the light beam. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles. Generally the beam profile is dependent on luminance L(z_o) and beam shape S(x,y;z_o), E(x,y;z_o)=L•S. Thus, by deriving the combined signal it may allow determining the longitudinal coordinate independent from luminance. In addition, using the combined signal allows determination of the distance z_o independent from the object size. Thus, the combined signal allows determination of the distance z_o independent from the material properties and/or reflective properties and/or scattering properties of the object and independent from alterations of the light source such as by manufacturing precision, heat, water, dirt, damages on the lens, or the like.

Each of the sensor signals may comprise at least one information of at least one area of the beam profile of the light beam. The light-sensitive areas 122 may be arranged such that a first sensor signal comprises information of a first area of the beam profile and a second sensor signal comprises information of a second area of the beam profile. The first area of the beam profile and second area of the beam profile may be one or both of adjacent or overlapping regions. The first area of the beam profile and the second area of the beam profile may be not congruent in area.

The evaluation device 128 may be configured to determine and/or to select the first area of the beam profile and the second area of the beam profile. The first area of the beam profile may comprise essentially edge information of the beam profile and the second area of the beam profile may comprise essentially center information of the beam profile. The beam profile may have a center, i.e. a maximum value of the beam profile and/or a center point of a plateau of the beam profile and/or a geometrical center of the light spot, and falling edges extending from the center. The second region may comprise inner regions of the cross section and the first region may comprise outer regions of the cross section. Preferably, the center information has a proportion of edge information of less than 10 %, more preferably of less than 5%, most preferably the center information comprises no edge content. The edge information may comprise information of the whole beam profile, in particular from center and edge regions. The edge information may have a proportion of center information of less than 10 %, preferably of less than 5%, more preferably the edge information comprises no center content. At least one area of the beam profile may be determined and/or selected as second area of the beam profile if it is close or around the center and comprises essentially center information. At least one area of the beam profile may be determined and/or selected as first area of the beam profile if it comprises at least parts of the falling edges of the cross section. For example, the whole area of the cross section may be determined as first region. The first area of the beam profile may be area A2 and the second area of the beam profile may be area A1. Similarly, the center signal and edge signal may also be determined by using segments of the beam profile such as circular segments of the beam profile. For example, the beam profile may be divided into two segments by a secant or a chord that does not pass the center of the beam profile. Thus, one segment will essentially contain edge information, while the other segment will contain essentially center information. For example, to further reduce the amount of edge information in the center signal, the edge signal may further be subtracted from the center signal.

The edge information may comprise information relating to a number of photons in the first area of the beam profile and the center information may comprise information relating to a number of photons in the second area of the beam profile. The evaluation device 128 may be adapted for determining an area integral of the beam profile. The evaluation device 128 may be adapted to determine the edge information by integrating and/or summing of the first area. The evaluation device 128 may be adapted to determine the center information by integrating and/or summing of the second area. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of edge and center signals may be

replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

- 5 Additionally or alternatively, the evaluation device 128 may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized, for example, by replacing the area integrals in the combined signal Q by a line integral along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or
10 cuts may result in improved distance information.

For example, the evaluation device 128 may be configured for evaluating the sensor signals, by

- a) determining at least one optical sensor 120 having the highest sensor signal and forming at least one center signal;
- 15 b) evaluating the sensor signals of the optical sensors 120 of the matrix 118 and forming at least one sum signal;
- c) determining at least one combined signal by combining the center signal and the sum signal; and
- d) determining the at least one longitudinal coordinate z of the selected feature by evaluating
20 the combined signal.

- For example, the center signal may be the signal of the at least one optical sensor 118 having the highest sensor signal out of the plurality of sensor signals generated by the optical sensors 120 of the entire matrix 118 or of a region of interest within the matrix 118, wherein the region of
25 interest may be predetermined or determinable within an image generated by the optical sensors of the matrix 118. The center signal may arise from a single optical sensor 120 or from a group of optical sensors 120, wherein, in the latter case, as an example, the sensor signals of the group of optical sensors 120 may be added up, integrated or averaged, in order to determine the center signal. The group of optical sensors 120 from which the center signal arises
30 may be a group of neighboring optical sensors, such as optical sensors 120 having less than a predetermined distance from the actual optical sensor having the highest sensor signal, or may be a group of optical sensors generating sensor signals being within a predetermined range from the highest sensor signal. The group of optical sensors 120 from which the center signal arises may be chosen as large as possible in order to allow maximum dynamic range. The
35 evaluation device 128 may be adapted to determine the center signal by integration of the plurality of sensor signals, for example the plurality of optical sensors around the optical sensor having the highest sensor signal.

- The determination of the center signal may be performed electronically, since a comparison of
40 sensor signals is fairly simply implemented by conventional electronics, or may be performed fully or partially by software. The detection of the center of the light spot, i.e. the detection of the center signal and/or of the at least one optical sensor from which the center signal arises, may be performed fully or partially electronically or fully or partially by using one or more software

algorithms. Specifically, the evaluation device 128 may comprise at least one center detector for detecting the at least one highest sensor signal and/or for forming the center signal. The center detector specifically may fully or partially be embodied in software and/or may fully or partially be embodied in hardware. The center detector may fully or partially be integrated into the at
5 least one sensor element and/or may fully or partially be embodied independently from the sensor element.

Specifically, the center signal may be selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance
10 from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor 120 having the highest sensor signal and a predetermined group of neighboring optical sensors 120; a sum of sensor signals from a group of optical sensors 120 containing the optical sensor 120 having the highest sensor signal and a predetermined group of neighboring optical sensors 120; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors 120 containing the optical sensor 120 having the highest sensor signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.
20

For example, the sum signal may be derived by adding up the sensor signals, integrating over the sensor signals or averaging over the sensor signals of the entire matrix 118 or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable
25 within an image generated by the optical sensors 120 of the matrix 118. When adding up, integrating over or averaging over the sensor signals, the actual optical sensors 120 from which the sensor signal is generated may be left out of the adding, integration or averaging or, alternatively, may be included into the adding, integration or averaging. The evaluation device 128 may be adapted to determine the sum signal by integrating signals of the entire matrix 118, or of the region of interest within the matrix 118. Further, when trapezoid beam profiles may be assumed, the determination of edge and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by
30 geometric considerations.
35

The sum signal may be derived from all sensor signals of the matrix 118, from the sensor signals within a region of interest or from one of these possibilities with the sensor signals arising from the optical sensors 120 contributing to the center signal excluded. In every case, a reliable
40 sum signal may be generated which may be compared with the center signal reliably, in order to determine the longitudinal coordinate. Generally, the sum signal may be selected from the group consisting of: an average over all sensor signals of the matrix 118; a sum of all sensor signals of the matrix 118; an integral of all sensor signals of the matrix 118; an average over all

sensor signals of the matrix 118 except for sensor signals from those optical sensors 120 contributing to the center signal; a sum of all sensor signals of the matrix 118 except for sensor signals from those optical sensors 120 contributing to the center signal; an integral of all sensor signals of the matrix 118 except for sensor signals from those optical sensors 120 contributing to the center signal; a sum of sensor signals of optical sensors 120 within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor 120 having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor 120 having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors 120 being located within a predetermined range from the optical sensor 120 having the highest sensor signal. Other options, however, exist. The summing may be performed fully or partially in software and/or may be performed fully or partially in hardware. A summing is generally possible by purely electronic means which, typically, may easily be implemented into the detector. Thus, in the art of electronics, summing devices are generally known for summing two or more electrical signals, both analogue signals and digital signals. Thus, the evaluation device 128 may comprise at least one summing device for forming the sum signal. The summing device may fully or partially be integrated into the sensor element or may fully or partially be embodied independently from the sensor element. The summing device may fully or partially be embodied in one or both of hardware or software.

The combined signal may be a signal which is generated by combining the center signal and the sum signal. Specifically, the combination may include one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa. Additionally or alternatively, the combined signal may comprise an arbitrary signal or signal combination which contains at least one item of information on a comparison between the center signal and the sum signal. The evaluation device 128 may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between the sensor signals. In particular, the evaluation device 128 may be configured to determine the at least one coordinate z of the by using at least one known, determinable or predetermined relationship between a quotient signal derived from the sensor signals and the longitudinal coordinate.

The comparison between the center signal and the sum signal specifically may be performed by forming one or more quotient signals. Thus, generally, the combined signal may be a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of the center signal and a linear combination of the sum signal and the center signal or vice versa; forming a quotient of the sum signal and a linear combination of the sum signal and the center signal or vice versa; forming a

quotient of an exponentiation of the center signal and an exponentiation of the sum signal or vice versa. Other options, however, exist. The evaluation device 128 may be configured for forming the one or more quotient signals. The evaluation device 128 may further be configured for determining the at least one longitudinal coordinate by evaluating the at least one quotient
5 signal.

The evaluation device 128 specifically may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal coordinate, in order to determine the at least one longitudinal coordinate. Thus, due to the reasons disclosed above and
10 due to the dependency of the properties of the light spot on the longitudinal coordinate, the combined signal Q typically is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, a simple quotient of the sensor signal s_{center} and the sum signal s_{sum} $Q = s_{\text{center}}/s_{\text{sum}}$ may be a monotonously decreasing function of the distance. Without wishing to be bound by this theory, it is believed that this is
15 due to the fact that, in the preferred setup described above, both the center signal s_{center} and the sum signal s_{sum} decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, the center signal s_{center} decreases more rapidly than the sum signal s_{sum} , since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. The
20 quotient of the center signal and the sum signal, thus, continuously decreases with increasing diameter of the light beam or diameter of the light spot on the light-sensitive areas of the optical sensors of the matrix. The quotient, further, is typically independent from the total power of the light beam, since the total power of the light beam forms a factor both in the center signal and in the sum sensor signal. Consequently, the combined signal Q may form a secondary signal which provides a unique and unambiguous relationship between the center signal and the sum
25 signal and the size or diameter of the light beam. Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship between the center signal and the sum signal on the one hand and the longitudinal coordinate on the other hand may exist. For the latter, reference e.g. may be made to one or more of the above-mentioned prior art documents, such as WO 2014/097181 A1. The predetermined relationship may be determined by
30 analytical considerations, such as by assuming a linear combination of Gaussian light beams, by empirical measurements, such as measurements measuring the combined signal and/or the center signal and the sum signal or secondary signals derived thereof as a function of the longitudinal coordinate of the object, or both.

The evaluation device 128 may be configured for using at least one predetermined relationship
40 between the combined signal and the longitudinal coordinate. The predetermined relationship may be one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship. The evaluation device 128 may comprise at least one data storage device for storing the predetermined relationship, such as a lookup list or a lookup table.

The sensor element 116 may be adapted to determine at least one reflection pattern. The reflection pattern may comprise at least one feature corresponding to at least one feature of the illumination pattern. The reflection pattern may comprise, in comparison to the illumination pattern, at least one distorted pattern, wherein the distortion depends on the distance of the object, such as surface properties of the object. The evaluation device 128 may be adapted to select at least one feature of the reflection pattern and to determine the longitudinal region of the selected feature of the reflection pattern by evaluating the combined signal Q from the sensor signals, as described above.

The evaluation device 128 is adapted to determine at least one displacement region 132 in at least one reference image 134 corresponding to the longitudinal region 130. The longitudinal region corresponds to the displacement region 132. The reference image 134 and the reflection image 126 may be images of the object 112 determined at different spatial positions having a fixed distance b, also called baseline. The evaluation device 128 may be adapted to determine an epipolar line 136 in the reference image 134. Relative position of the reference image 134 and reflection image 126 may be known. For example, relative position of the reference image 134 and reflection image 126 may be stored within at least one storage unit of the evaluation device 128. The evaluation device 128 may be adapted to determine a straight line 138 extending from the selected reflection feature 129 of the reflection image 126. The straight line 138 may comprise possible object positions 114. The straight line 138 and the baseline b span an epipolar plane 140. As the reference image 134 is determined at a different relative position from the reflection image, the corresponding reference features may be imaged on the epipolar line 136 in the reference image 134.

For example, in the embodiment shown in Figure 1, the reference image 134 may be an image of the illumination pattern at an image plane at a position of the illumination source 124. The evaluation device 128 may be adapted to determine the displacement region 132 in the reference image 134 corresponding to the longitudinal region 130 of the selected feature 129 of the reflection pattern. The evaluation device 128 may be adapted to match the selected feature 129 of the reflection pattern with at least one feature of the reference pattern within the displacement region 132. The illumination source 124 and the sensor element 116 may be separated by a fixed distance.

The displacement region 132 may extend along the epipolar line 136. The evaluation device 128 may be adapted to determine the reference feature along the epipolar line 136 corresponding to the longitudinal coordinate z and to determine an extent of the displacement region 132 along the epipolar line 136 corresponding to the error interval $\pm\epsilon$. The evaluation device 128 is adapted to match the selected reflection feature 129 with at least one reference feature within the displacement region 132. The evaluation device 128 may be adapted to match the selected feature of the reflection image with the reference feature within the displacement region 132 by using at least one evaluation algorithm considering the determined longitudinal coordinate z. The evaluation algorithm may be a linear scaling algorithm.

The evaluation device 128 may be adapted to determine a displacement of the matched reference feature and the selected reflection feature 129. The evaluation device 128 may be adapted to determine a longitudinal information of the matched feature using a predetermined relationship between a longitudinal coordinate and the displacement. For example, the longitudinal information may be a distance value. The evaluation device 128 may be adapted to determine the pre-determined relationship by using triangulation methods. In case position of the selected reflection feature 129 in the reflection image 126 and position of the matched reference feature and/or relative displacement of the selected reflection feature and the matched reference feature are known, a longitudinal coordinate of the corresponding object feature 114 may be determined by triangulation. Thus, the evaluation device 128 may be adapted to select, for example subsequent and/or column by column, a reflection feature and to determine for each potential position of the reference feature the corresponding distance value using triangulation. For example, Figure 1 shows possible projection lines resulting in reflection features in the reflection image 126 and corresponding to reference features in the reference image 134. In addition, intersection points of these lines are shown corresponding to object positions. Displacement and corresponding distance value may be stored in at least one storage device of the evaluation device. The evaluation device 128 may, as an example, comprise at least one data processing device, such as at least one processor, at least one DSP, at least one FPGA and/or at least one ASIC. Further, for storing the at least one predetermined or determinable relationship between the longitudinal coordinate z and the displacement, the at least one data storage device may be provided, such as for providing one or more look-up tables for storing the predetermined relationship.

In Figure 2, an embodiment of the detector 110 is shown, wherein the detector 110 may comprise at least two sensor elements 116 each having a matrix 118 of optical sensors 120. At least one first sensor element 142 and at least one second sensor element 144 may be positioned at different spatial positions. A relative distance b between the first sensor element 142 and the second element 144 may be fixed. The at least one first sensor element 142 may be adapted to determine at least one first reflection pattern and the at least one second sensor element 144 may be adapted to determine at least one second reflection pattern. The evaluation device 128 may be adapted to select at least one image determined by the first sensor element 142 or the second sensor element 144 as reflection image and to select at least one image determined by the other one of the first sensor element 142 or the second sensor element 144 as reference image. In Figure 2, the image of the first sensor element 142 is selected as reflection image 126, whereas the image of the second sensor element 144 is selected as reference image 134. The evaluation device 128 may be adapted to select the at least one reflection feature in the reflection pattern and to determine the longitudinal region 130 of the selected feature by evaluating the combined signal Q from the sensor signals, as outlined with respect to Figure 1. The evaluation device 128 may be adapted to determine the displacement region 132 in the reference image 134 corresponding to the longitudinal region 120 of the selected feature 129 of the reflection pattern. The evaluation device 128 may be adapted to match the selected feature 129

of the reflection pattern with at least one feature of the reference pattern within the displacement region 132, as outlined with respect to Figure 1.

Using the combined sensor signal allows to estimate distances, such as the longitudinal coordinate z within the error interval. By determining the displacement region 132 corresponding to the estimated longitudinal coordinate and the corresponding error interval allows to reduce possible number of solutions along the epipolar line 136 significantly. The number of solutions may even be reduced to one. Subsequent matching of the selected reflection feature and reference feature may enhance accuracy. Determining of the longitudinal coordinate z and the error interval may be performed during a pre-evaluation before matching the selected reflection feature 129 and reference feature. This may allow reducing the computational demand such that it is possible to significantly reduce costs and to allow a use in mobile device or outdoor devices, where battery life or ventilation or heat management is an issue. Furthermore, generally in triangulation systems the baseline has to be large in order to detect large distances. Pre-evaluation of the longitudinal coordinate z and error interval using the combined sensor signal and subsequent matching of the selected reflection feature 129 and reference feature may allow using short baselines such that it may be possible to provide a compact device. Furthermore, pre-evaluation of the longitudinal coordinate z and error interval using the combined sensor signal and subsequent matching of the selected reflection feature and reference feature may enhance accuracy in comparison the triangulation systems. Furthermore, it may be possible to use denser pattern in order to enhance further resolution or to use a less dense pattern in order to increase power per point.

Figure 3 shows, in a highly schematic illustration, an exemplary embodiment of the detector 110, for example according to the embodiment shown in Figure 2. The detector 110 specifically may be embodied as a camera 146 and/or may be part of a camera 146. The camera 146 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible. Fig. 3 further shows an embodiment of a detector system 148, which, besides the at least one detector 110, comprises one or more beacon devices 150, which, in this example, may be attached and/or integrated into an object 112, the position of which shall be detected by using the detector 110. Fig. 3 further shows an exemplary embodiment of a human-machine interface 152, which comprises the at least one detector system 148 and, further, an entertainment device 154, which comprises the human-machine interface 152. The figure further shows an embodiment of a tracking system 156 for tracking a position of the object 112, which comprises the detector system 148. The components of the devices and systems shall be explained in further detail below.

Fig. 3 further shows an exemplary embodiment of a scanning system 158 for scanning a scenery comprising the object 112, such as for scanning the object 112 and/or for determining at least one position of the at least one object 112. The scanning system 158 comprises the at least one detector 110, and, further, optionally, the at least one illumination source 124 as well as, optionally, at least one further illumination source, not depicted here. The illumination source

124, generally, is configured to emit at least one illumination light beam, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 150 and/or on a surface of the object 112. The scanning system 158 may be designed to generate a profile of the scenery including the object 112 and/or a profile of the object 112, and/or may be designed to generate at least one item of information about the distance between the at least one dot and the scanning system 158, specifically the detector 110, by using the at least one detector 110.

As outlined above, an exemplary embodiment of the detector 110 which may be used in the setup of Fig. 3 is shown in Fig. 2. Thus, the detector 110, besides the optical sensors 120 comprises at least one evaluation device 128, having e.g. at least one divider 160 and/or the at least one position evaluation device 162, as symbolically depicted in Fig. 3. The components of the evaluation device 128 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 110. Besides the possibility of fully or partially combining two or more components, one or more of the optical sensors 120 and one or more of the components of the evaluation device 128 may be interconnected by one or more connectors 164 and/or by one or more interfaces, as symbolically depicted in Fig. 3. Further, the one or more connectors 164 may comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 164, the evaluation device 128 may fully or partially be integrated into one or both of the optical sensors 120 and/or into a housing 166 of the detector 110. Additionally or alternatively, the evaluation device 128 may fully or partially be designed as a separate device.

In this exemplary embodiment, the object 112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 168, the position of which may be manipulated by a user 170. As an example, the object 112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 112 are possible. Further, the user 170 himself or herself may be considered as the object 112, the position of which shall be detected.

As outlined above, the detector 110 comprises optical sensors 120. The optical sensors 120 may be located inside the housing 166. Further, the detector 110 may comprise the at least one transfer device 127 such as one or more optical systems, preferably comprising one or more lenses. An opening 172 inside the housing 166, which, preferably, is located concentrically with regard to an optical axis 174 of the detector 110, preferably defines a direction of view 176 of the detector 110. A coordinate system 178 may be defined, in which a direction parallel or anti-parallel to the optical axis 174 may be defined as a longitudinal direction, whereas directions perpendicular to the optical axis 174 may be defined as transversal directions. In the coordinate system 178, symbolically depicted in Fig. 3, a longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other types of coordinate systems are feasible, such as non-Cartesian coordinate systems.

One or more light beams 180, such as light beams of the illumination pattern, are propagating from the object 112 and/or from one or more of the beacon devices 150, towards the detector 110. The detector 110 is configured for determining a position of the at least one object 112. In case no illumination source 124 is used, the beacon devices 150 and/or at least one of these
5 beacon devices 150 may be or may comprise active beacon devices with an integrated illumination source such as a light-emitting diode. Alternatively, ambient light sources may be used.

The light beam 180, for example generated by the illumination source 124 such as the at least one illumination pattern, may be directed towards the object by using one or more optical elements. The object 112 may in response to the illumination generate the at least one reflection
10 light beam 182. For details of the evaluation, reference may be made to Fig. 1 above.

As outlined above, the determination of the position of the object 112 and/or a part thereof by using the detector 110 may be used for providing a human-machine interface 152, in order to
15 provide at least one item of information to a machine 184. In the embodiments schematically depicted in Fig. 3, the machine 184 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 128 may even be fully or partially integrated into the machine 184, such as into the computer.

As outlined above, Fig. 3 also depicts an example of a tracking system 156, configured for tracking the position of the at least one object 112 and/or of parts thereof. The tracking system 156 comprises the detector 110 and at least one track controller 186. The track controller 186 may be adapted to track a series of positions of the object 112 at specific points in time. The track controller 186 may be an independent device and/or may be fully or partially integrated
20 into the machine 184, specifically the computer, as indicated in Fig. 3 and/or into the evaluation device 128.

Similarly, as outlined above, the human-machine interface 152 may form part of an entertainment device 154. The machine 184, specifically the computer, may also form part of the entertainment device 154. Thus, by means of the user 170 functioning as the object 112 and/or by
30 means of the user 170 handling a control device functioning as the object 112, the user 170 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer.

Referring to Figure 4, the detector 110 such as the detector as described with respect to Figures 1 to 3 may be adapted to determine depth information, in particular absolute depth information, from a radiance ratio of at least two asymmetric regions of a light beam profile on the at least two optical sensors 120. For example, the detector 110 may comprise a plurality of optical sensors arranged in the matrix 118. The detector 110 may be adapted to determine depth information from a radiance ratio of at least two asymmetric regions within an enclosed, in particular, defocused beam profile captured by a single matrix of optical sensors such as a CMOS detector. In particular, the detector 110 may be adapted to determine the depth information using the radiance ratio independent of a certain object size range. As outlined above, this principle is
40

called Distance by Photon Ratio (DPR). In one embodiment, the light beam 180 may illuminate the sensor element 116 with at least one pattern comprising at least one feature point. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. The evaluation device 128 may be configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

- wherein x and y are transversal coordinates, A1 and A2 are areas of the beam profile at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors. The central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

In the embodiment shown in Figure 4, the reflection light beam 182 propagating from the object 112 to the detector 110 may illuminate the matrix 118 with at least one line pattern 188. The line pattern 188 may be generated by the object 112 for example in response to an illumination by the at least one illumination source 124 with an illumination pattern comprising at least one illumination line pattern. A1 may correspond to an area with a full line width of the line pattern 188 in the matrix 118. The line pattern 188 in the matrix 118 may be widened and/or displaced compared to the line pattern of the illumination pattern such that a line width in the matrix 118 is increased. In particular, the line width of the line pattern 188 in the matrix 118 may change from one column to another column. A2 may be a central area of the line pattern 188 in the matrix 118. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern 188 may be segmented in the matrix 118. Each of the columns may comprise center information of intensity in the central area of the line pattern 188 and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern 188.

35

Figures 5A to C show three embodiments of a hexagonal illumination pattern. The illumination source 124 may be adapted to generate at least one illumination pattern for illuminating the object 112. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. Specifically, the illumination source 124 may comprise at least one laser

and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The illumination pattern may comprise at least one feature such as a point or symbol. The illumination pattern may comprise a plurality of features. The illumination pattern may com-
5 prise an arrangement of periodic or non-periodic features. The illumination pattern may be generated by ambient light, such as by at least one ambient light source, or by the at least one illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern, a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one qua-
10 siperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines. For example, the illumination source may be adapted to generate and/or to
15 project a cloud of points. The illumination pattern may comprise regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern, or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that hexagonal pattern may be preferred. A distance between two features of the illumination pattern and/or an area of the at least one illumination feature
20 may depend on the circle of confusion in the image.

The illumination features of the illumination pattern may be arranged such that only few reference features are positioned on an epipolar line. As shown in Figure 5A, the illumination pattern may comprise at least one hexagonal pattern, wherein the individual points are positioned on
25 epipolar lines 190. As shown in Figure 5B, the illumination pattern may comprise at least one hexagonal pattern, wherein the pattern is rotated relative to the baseline. Such a positioning of the illumination features allows enhancing distance between the individual points on each epipolar line. For example as shown in Figure 5C, the illumination pattern may comprise at least one displaced hexagonal pattern, wherein individual points of the hexagonal pattern are dis-
30 placed by a random distance from the regular position, for example orthogonal to the epipolar line of the point. The displacement of the individual points may be smaller than half of the distance between two parallel epipolar lines, preferably smaller than one fourth of the distance between two parallel epipolar lines. The displacement of the individual points may be as such that two points are not displaced above each other

35
Figure 6 shows an embodiment of a scanning system 158. The scanning system 158 may be adapted as a line scanning device. In particular, the scanning system 158 may comprise at least one sensor line or row of optical sensors 120. Furthermore, the scanning system 158 may comprise the at least one transfer device 127 and the at least one illumination source 124. Triangu-
40 lation systems require a sufficient baseline, however due to the baseline in the near field no detection may be possible. Near field detection may be possible if the light spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. Thus, in triangulation systems, the non-

zero baseline will always lead to a substantial reduction in the measurement range, in the near field, and/or in the far field. Reducing the baseline as possible with the detector according to the present invention will thus always increase the measurement range. Further, these near field and far field problems can be overcome by using the scanning system 158 of Figure 6. The scanning system 158 may be adapted to detect a plurality of light beams 182 propagating from the object 112 to the scanning system 158 on the CMOS line. The light beams 182 may be generated at different position on the object 112 or by movement of the object 112. The scanning system 158 may be adapted to determine at least one longitudinal coordinate for each of the light points by determining the combined signal Q as described above.

Patent claims

1. A detector (110) for determining a position of at least one object (112), the detector (110) comprising
 - 5 - at least one sensor element (116) having a matrix (118) of optical sensors (120), the optical sensors (120) each having a light-sensitive area (122), wherein each optical sensor (120) is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area (122) by a reflection light beam (182) propagating from the object (112) to the detector (110), wherein the sensor element (116) is adapted to determine at least one reflection image (126);
 - 10 - at least one evaluation device (128), wherein the evaluation device (128) is adapted to select at least one reflection feature of the reflection image (126), wherein the evaluation device (128) is configured for determining at least one longitudinal region (130) of the selected reflection feature of the reflection image (134) by evaluating a combined signal Q from the sensor signals, wherein the evaluation device (128) is adapted to determine at least one displacement region (132) in at least one reference image (134) corresponding to the longitudinal region (130), wherein the evaluation device (128) is adapted to match the selected reflection feature with at least one reference feature within the displacement region (132).
 - 15
 - 20
2. The detector (110) according to the preceding claim, wherein the evaluation device (128) is adapted to determine a displacement of the matched reference feature and the selected reflection feature, wherein the evaluation device (128) is adapted to determine a longitudinal information of the matched feature using a predetermined relationship between a longitudinal coordinate and the displacement.
- 25
3. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.
- 30
4. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is configured for using at least one predetermined relationship between the combined signal Q and the longitudinal region for determining the longitudinal region.
- 35
5. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is adapted to determine at least one longitudinal coordinate z of the selected reflection feature by evaluating the combined signal Q, wherein the longitudinal region (130) is given by the longitudinal coordinate z and an error interval $\pm\epsilon$.
- 40
6. The detector (110) according any one of the preceding claims, wherein the reference image (134) and the reflection image (126) are images of the object determined at different spatial

positions having a fixed distance, wherein the evaluation device (128) is adapted to determine an epipolar line (136) in the reference image (134).

7. The detector (110) according to the two preceding claims, wherein the displacement region (132) extends along the epipolar line (136), wherein the evaluation device (128) is adapted to determine the reference feature along the epipolar line (136) corresponding to the longitudinal coordinate z and to determine an extent of the displacement region (132) along the epipolar line (136) corresponding to the error interval $\pm \epsilon$.
8. The detector (110) according to the preceding claim, wherein the evaluation device (128) is configured to perform the following steps:
 - Determining the displacement region for the image position of each reflection feature;
 - Assigning an epipolar line to the displacement region of each reflection feature such as by assigning the epipolar line closest to a displacement region and/or within a displacement region and/or closest to a displacement region along a direction orthogonal to the epipolar line;
 - Assigning and/or determining at least one reference feature to each reflection feature such as by assigning the reference feature closest to the assigned displacement region and/or within the assigned displacement region and/or closest to the assigned displacement region along the assigned epipolar line and/or within the assigned displacement region along the assigned epipolar line.
9. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is adapted to match the selected feature of the reflection image (126) with the reference feature within the displacement region (132) by using at least one evaluation algorithm considering the determined longitudinal coordinate z , wherein the evaluation algorithm is a linear scaling algorithm.
10. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A_1 and A_2 are different areas of at least one beam profile of the reflection light beam (182) at the sensor position, and $E(x, y, z_o)$ denotes the beam profile given at the object distance z_o , wherein each of the sensor signals comprises at least one information of at least one area of the beam profile of the reflection light beam.

11. The detector (110) according to the preceding claim, wherein the light-sensitive areas (122) are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.
12. The detector (110) according to the preceding claim, wherein the evaluation device (128) is configured to determine the first area of the beam profile and the second area of the beam profile, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile, wherein the edge information comprises information relating to a number of photons in the first area of the beam profile and the center information comprises information relating to a number of photons in the second area of the beam profile.
13. The detector (110) according to any one of the preceding claims, wherein the at least one evaluation device (128) is configured for evaluating the sensor signals, by
- a) determining at least one optical sensor (120) having the highest sensor signal and forming at least one center signal;
 - b) evaluating the sensor signals of the optical sensors (120) of the matrix (118) and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and
 - d) determining the longitudinal region by evaluating the combined signal.
14. The detector (110) according to the preceding claim, wherein the combined signal is a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa.
15. The detector (110) according to any one of the preceding claims, wherein the detector (110) comprises at least one illumination source (124), wherein the illumination source (124) is adapted to generate at least one illumination pattern for illumination of the object (112), wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern; at least one pattern comprising at least one pre-known feature.
16. The detector (110) according to the preceding claim, wherein the sensor element (116) is adapted to determine at least one reflection pattern, wherein the evaluation device (128) is adapted to select at least one feature of the reflection pattern and to determine the longitudinal region (130) of the selected feature of the reflection pattern by evaluating the combined signal Q from the sensor signals.

17. The detector (110) according to the preceding claim, wherein the reference image (134) is an image of the illumination pattern at an image plane at a position of the illumination source (124), wherein the evaluation device (128) is adapted to determine the displacement region (132) in the reference image (134) corresponding to the longitudinal region (130) of the selected feature of the reflection pattern, wherein the evaluation device (128) is adapted to match the selected feature of the reflection pattern with at least one feature of the reference pattern within the displacement region (132).
18. The detector (110) according to any one of the three preceding claims, wherein the detector (110) comprises at least two sensor elements (116) each having a matrix (118) of optical sensors (120), where at least one first sensor element (142) and at least one second sensor element (144) are positioned at different spatial positions, wherein a relative distance between the first sensor element (142) and the second element (144) is fixed, wherein the at least one first sensor element (142) is adapted to determine at least one first reflection pattern and the at least one second sensor element (144) is adapted to determine at least one second reflection pattern, wherein the evaluation device (128) is adapted to select at least one image determined by the first sensor element (142) or the second sensor element (144) as reflection image (126) and to select at least one image determined by the other one of the first sensor element (142) or the second sensor element (144) as reference image (134).
19. A detector system (148) for determining a position of at least one object (112), the detector system (148) comprising at least one detector (110) according to any one of the preceding claims, the detector system (148) further comprising at least one beacon device (150) adapted to direct at least one light beam towards the detector (110), wherein the beacon device (150) is at least one of attachable to the object (112), holdable by the object (112) and integratable into the object (112).
20. A human-machine interface (152) for exchanging at least one item of information between a user (170) and a machine (184), wherein the human-machine interface (152) comprises at least one detector system (148) according to the preceding claim, wherein the at least one beacon device (150) is adapted to be at least one of directly or indirectly attached to the user (170) and held by the user (170), wherein the human-machine interface (152) is designed to determine at least one position of the user (170) by means of the detector system (148), wherein the human-machine interface (152) is designed to assign to the position at least one item of information.
21. An entertainment device (154) for carrying out at least one entertainment function, wherein the entertainment device (154) comprises at least one human-machine interface (152) according to the preceding claim, wherein the entertainment device (154) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (152), wherein the entertainment device (154) is designed to vary the entertainment function in accordance with the information.

22. A tracking system (156) for tracking a position of at least one movable object (112), the tracking system (156) comprising at least one detector system (148) according to any one of the preceding claims referring to a detector system (148), the tracking system (156) further comprising at least one track controller (186), wherein the track controller (186) is adapted to track a series of positions of the object (112) at specific points in time.
23. A scanning system (158) for determining a depth profile of a scenery, the scanning system comprising at least one detector (110) according to any of the preceding claims referring to a detector, the scanning system (158) further comprising at least one illumination source (124) adapted to scan the scenery with at least one light beam.
24. A camera (146) for imaging at least one object (112), the camera (146) comprising at least one detector (110) according to any one of the preceding claims referring to a detector.
25. A method for determining a position of at least one object (112) by using at least one detector (110) according to any one of the preceding claims referring to a detector, the method comprising the following steps:
- generating at least two sensor signals in response to an illumination of at least one sensor element (116) having a matrix (118) of optical sensors (120) by at least one reflection light beam (182) propagating from the object (112) to the detector (110), the optical sensors (120) each having a light-sensitive area (122);
 - determining at least one reflection image (126) by using the sensor element (116);
 - selecting at least one reflection feature of the reflection image (126) and evaluating the sensor signals by using at least one evaluation device (128), thereby, determining at least one longitudinal region (130) of the selected reflection feature, wherein the evaluating comprises evaluating a combined signal Q from the sensor signals;
 - determining at least one displacement region (132) in at least one reference image (134) corresponding to the longitudinal region (130);
 - matching the selected reflection feature with at least one reference feature within the displacement region (132).
26. A use of the detector (110) according to any one of the preceding claims relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a logistics application; a tracking application; an outdoor application; a mobile application; a communication application; a photography application; a machine vision application; a robotics application; a quality control application; a manufacturing application;

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

This collection of information is required by 37 CFR 1.97 and 1.98. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 1 hour to complete, including gathering, preparing and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these records.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

Detector for determining a position of at least one object

Description

5 Field of the invention

The invention relates to a detector and a method for determining a position of at least one object. The invention further relates to a human-machine interface for exchanging at least one item of information between a user and a machine, an entertainment device, a tracking system, a camera, a scanning system and various uses of the detector device. The devices, methods and uses according to the present invention specifically may be employed for example in various areas of daily life, gaming, traffic technology, production technology, security technology, photography such as digital photography or video photography for arts, documentation or technical purposes, medical technology or in the sciences. Further, the invention specifically may be used for scanning one or more objects and/or for scanning a scenery, such as for generating a depth profile of an object or of a scenery, e.g. in the field of architecture, metrology, archaeology, arts, medicine, engineering or manufacturing. However, other applications are also possible.

Prior art

Optical 3D sensing methods generally may determine unreliable results in case of environment causing multiple reflections, with biasing light sources, or reflective measurement objects. Furthermore, 3D sensing methods, such as triangulation methods using structured light or stereo cameras, with imaging capabilities often suffer from a high demand of computational power to solve correspondence problems. Necessary computational power may result in high costs for processors or Field Programmable Gate Arrays (FPGAs), for heat removal in view of ventilation requirements or water proof housing difficulties, for electrical power consumption, in particular in mobile devices, and, in addition, in measurement uncertainties. The high demand in computational power may be prohibitive to realize real-time applications, high framerates or even standards video speed frame rates of 25 frames per second.

A large number of optical devices are known from the prior art using triangulation imaging methods. For example, structured light methods or stereo methods are known. For example, passive stereo methods using two cameras in a fixed relative orientation or active stereo technologies, where an additional light projector is used. Another example is the structures light approach, where one light projector and one camera in a fixed relative orientation are used. In order to determine a depth image via triangulation, the correspondence problem has to be solved first. Therefore, in passive stereo camera techniques enough corresponding feature points have to be identified in both camera views. In structured light approaches correspondences between pre-stored and projected pseudo random light patterns have to be determined. For a robust solution of these correspondence problems computational imaging algorithms such as algorithms scaling approximately quadratically with the number of points in the projected point pattern have to be employed. In structured light methods, for example, using a stereo system comprising two detectors having a fixed relative distance, a light source projects a pat-

tern such as points, pseudo-random, random, non-periodic or irregular point patterns, or the like. Each of the detectors generates an image of a reflection pattern and an image analysis task is to identify corresponding features in the two images. Due to fixed relative position a corresponding feature point selected in one of the two images lies along an epipolar line in the other image. However, solving the so-called correspondence problem may be difficult. In stereo and triangulation systems, the distance of all feature points along the epipolar line have to have reasonable correspondence among each other. A correspondence decision cannot be made one after another. If one correspondence is wrong, this has implications for other feature points, such as invisibility. This usually yields quadratic scaling evaluation algorithms.

For example, US 2008/0240502 A1 and US 2010/0118123 A1 describe an apparatus for mapping an object including an illumination assembly, which includes a single transparency containing a fixed pattern of spots. A light source transilluminates the single transparency with optical radiation so as to project the pattern onto the object. An image capture assembly captures an image of the pattern that is projected onto the object using the single transparency. A processor processes the image captured by the image capture assembly as to reconstruct a three-dimensional map of the object.

US 2008/118143 A1 describes a method and apparatus for obtaining an image to determine a three dimensional shape of a stationary or moving object using a bi dimensional coded light pattern having a plurality of distinct identifiable feature types. The coded light pattern is projected on the object such that each of the identifiable feature types appears at most once on predefined sections of distinguishable epipolar lines. An image of the object is captured and the reflected feature types are extracted along with their location on known epipolar lines in the captured image. Displacements of the reflected feature types along their epipolar lines from reference coordinates thereupon determine corresponding three dimensional coordinates in space and thus a 3D mapping or model of the shape of the object at any point in time.

US 2009/066929 A1 describes establishing of the correspondence of the points for creation of a range image with stereo cameras. The scene is illuminated twice; thereof at least once with a random or pseudo random pattern. For both cameras, an image is taken for each of the illuminations and the quotient of brightnesses is calculated pixelwise. The correspondence is established on the basis of a comparison of the quotient of pixels on epipolar lines of different cameras. The illumination pattern is preferably highly modulated along the epipolar line; transversally or diagonally to it, it is not or only slightly modulated. For illumination, a projection unit is used which in a preferred arrangement comprises two superposed grating patterns which have a distance to each other, with at least one varying in a pseudo random manner, and with two closely neighboring light sources which shine through the gratings and thereby generate different pseudo random patterns, especially moiré patterns.

Despite the advantages implied by the above-mentioned devices and detectors, several technical challenges remain. Thus, the evaluation algorithms used require high computation power which is a severe cost driver. Furthermore, due to energy consumption and heat production of

the required computational resources, the computational demand limits use of such 3D sensor methods in outdoor and mobile applications.

Problem addressed by the invention

5

It is therefore an object of the present invention to provide devices and methods facing the above-mentioned technical challenges of known devices and methods. Specifically, it is an object of the present invention to provide devices and methods which reliably may determine a position of an object in space, preferably with a low technical effort and with low requirements in terms of technical resources and cost.

10

Summary of the invention

15

This problem is solved by the invention with the features of the independent patent claims. Advantageous developments of the invention, which can be realized individually or in combination, are presented in the dependent claims and/or in the following specification and detailed embodiments.

20

As used in the following, the terms "have", "comprise" or "include" or any arbitrary grammatical variations thereof are used in a non-exclusive way. Thus, these terms may both refer to a situation in which, besides the feature introduced by these terms, no further features are present in the entity described in this context and to a situation in which one or more further features are present. As an example, the expressions "A has B", "A comprises B" and "A includes B" may both refer to a situation in which, besides B, no other element is present in A (i.e. a situation in which A solely and exclusively consists of B) and to a situation in which, besides B, one or more further elements are present in entity A, such as element C, elements C and D or even further elements.

25

Further, it shall be noted that the terms "at least one", "one or more" or similar expressions indicating that a feature or element may be present once or more than once typically will be used only once when introducing the respective feature or element. In the following, in most cases, when referring to the respective feature or element, the expressions "at least one" or "one or more" will not be repeated, notwithstanding the fact that the respective feature or element may be present once or more than once.

35

Further, as used in the following, the terms "preferably", "more preferably", "particularly", "more particularly", "specifically", "more specifically" or similar terms are used in conjunction with optional features, without restricting alternative possibilities. Thus, features introduced by these terms are optional features and are not intended to restrict the scope of the claims in any way. The invention may, as the skilled person will recognize, be performed by using alternative features. Similarly, features introduced by "in an embodiment of the invention" or similar expressions are intended to be optional features, without any restriction regarding alternative embodiments of the invention, without any restrictions regarding the scope of the invention and without

40

any restriction regarding the possibility of combining the features introduced in such a way with other optional or non-optional features of the invention.

In a first aspect of the present invention a detector for determining a position of at least one object is disclosed. As used herein, the term "object" refers to a point or region emitting at least one light beam. The light beam may originate from the object, such as by the object and/or at least one illumination source integrated or attached to the object emitting the light beam, or may originate from a different illumination source, such as from an illumination source directly or indirectly illuminating the object, wherein the light beam is reflected or scattered by the object. As used herein, the term "position" refers to at least one item of information regarding a location and/or orientation of the object and/or at least one part of the object in space. Thus, the at least one item of information may imply at least one distance between at least one point of the object and the at least one detector. As will be outlined in further detail below, the distance may be a longitudinal coordinate or may contribute to determining a longitudinal coordinate of the point of the object. Additionally or alternatively, one or more other items of information regarding the location and/or orientation of the object and/or at least one part of the object may be determined. As an example, additionally, at least one transversal coordinate of the object and/or at least one part of the object may be determined. Thus, the position of the object may imply at least one longitudinal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one transversal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one orientation information of the object, indicating an orientation of the object in space.

The detector comprises:

- at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by a reflection light beam propagating from the object to the detector, wherein the sensor element is adapted to determine at least one reflection image;
- at least one evaluation device, wherein the evaluation device is adapted to select at least one reflection feature of the reflection image, wherein the evaluation device is configured for determining at least one longitudinal region of the selected reflection feature of the reflection image by evaluating a combined signal Q from the sensor signals, wherein the evaluation device is adapted to determine at least one displacement region in at least one reference image corresponding to the longitudinal region, wherein the evaluation device is adapted to match the selected reflection feature with at least one reference feature within the displacement region.

As used herein, the term "sensor element" generally refers to a device or a combination of a plurality of devices configured for sensing at least one parameter. In the present case, the parameter specifically may be an optical parameter, and the sensor element specifically may be an optical sensor element. The sensor element may be formed as a unitary, single device or as

a combination of several devices. As further used herein, the term "matrix" generally refers to an arrangement of a plurality of elements in a predetermined geometrical order. The matrix, as will be outlined in further detail below, specifically may be or may comprise a rectangular matrix having one or more rows and one or more columns. The rows and columns specifically may be arranged in a rectangular fashion. It shall be outlined, however, that other arrangements are feasible, such as nonrectangular arrangements. As an example, circular arrangements are also feasible, wherein the elements are arranged in concentric circles or ellipses about a center point. For example, the matrix may be a single row of pixels. Other arrangements are feasible.

10 The optical sensors of the matrix specifically may be equal in one or more of size, sensitivity and other optical, electrical and mechanical properties. The light-sensitive areas of all optical sensors of the matrix specifically may be located in a common plane, the common plane preferably facing the object, such that a light beam propagating from the object to the detector may generate a light spot on the common plane.

15

As used herein, an "optical sensor" generally refers to a light-sensitive device for detecting a light beam, such as for detecting an illumination and/or a light spot generated by at least one light beam. As further used herein, a "light-sensitive area" generally refers to an area of the optical sensor which may be illuminated externally, by the at least one light beam, in response to which illumination the at least one sensor signal is generated. The light-sensitive area may specifically be located on a surface of the respective optical sensor. Other embodiments, however, are feasible. As used herein, the term "the optical sensors each having at least one light sensitive area" refers to configurations with a plurality of single optical sensors each having one light sensitive area and to configurations with one combined optical sensor having a plurality of light sensitive areas. Thus, the term "optical sensor" furthermore refers to a light-sensitive device configured to generate one output signal, whereas, herein, a light-sensitive device configured to generate two or more output signals, for example at least one CCD and/or CMOS device, is referred to as two or more optical sensors. As will further be outlined in detail below, each optical sensor may be embodied such that precisely one light-sensitive area is present in the respective optical sensor, such as by providing precisely one light-sensitive area which may be illuminated, in response to which illumination precisely one uniform sensor signal is created for the whole optical sensor. Thus, each optical sensor may be a single area optical sensor. The use of the single area optical sensors, however, renders the setup of the detector specifically simple and efficient. Thus, as an example, commercially available photo-sensors, such as commercially available silicon photodiodes, each having precisely one sensitive area, may be used in the set-up. Other embodiments, however, are feasible. Thus, as an example, an optical device comprising two, three, four or more than four light-sensitive areas may be used which is regarded as two, three, four or more than four optical sensors in the context of the present invention. As outlined above, the sensor element comprises a matrix of optical sensors. Thus, as an example, the optical sensors may be part of or constitute a pixelated optical device. As an example, the optical sensors may be part of or constitute at least one CCD and/or CMOS device having a matrix of pixels, each pixel forming a light-sensitive area.

20

25

30

35

40

As outlined above, the optical sensors specifically may be or may comprise photodetectors, preferably inorganic photodetectors, more preferably inorganic semiconductor photodetectors, most preferably silicon photodetectors. Specifically, the optical sensors may be sensitive in the infrared spectral range. All of the optical sensors of the matrix or at least a group of the optical sensors of the matrix specifically may be identical. Groups of identical optical sensors of the matrix specifically may be provided for different spectral ranges, or all optical sensors may be identical in terms of spectral sensitivity. Further, the optical sensors may be identical in size and/or with regard to their electronic or optoelectronic properties.

Specifically, the optical sensors may be or may comprise inorganic photodiodes which are sensitive in the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers. Specifically, the optical sensors may be sensitive in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm. Infrared optical sensors which may be used for optical sensors may be commercially available infrared optical sensors, such as infrared optical sensors commercially available from Hamamatsu Photonics Deutschland GmbH, D-82211 Herrsching am Ammersee, Germany. Thus, as an example, the optical sensors may comprise at least one optical sensor of an intrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge photodiode, an InGaAs photodiode, an extended InGaAs photodiode, an InAs photodiode, an InSb photodiode, a HgCdTe photodiode. Additionally or alternatively, the optical sensors may comprise at least one optical sensor of an extrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge: Au photodiode, a Ge: Hg photodiode, a Ge: Cu photodiode, a Ge: Zn photodiode, a Si: Ga photodiode, a Si: As photodiode. Additionally or alternatively, the optical sensors may comprise at least one bolometer, preferably a bolometer selected from the group consisting of a VO bolometer and an amorphous Si bolometer.

The matrix may be composed of independent optical sensors. Thus, a matrix of inorganic photodiodes may be composed. Alternatively, however, a commercially available matrix may be used, such as one or more of a CCD detector, such as a CCD detector chip, and/or a CMOS detector, such as a CMOS detector chip.

Thus, generally, the optical sensors of the detector may form a sensor array or may be part of a sensor array, such as the above-mentioned matrix. Thus, as an example, the detector may comprise an array of optical sensors, such as a rectangular array, having m rows and n columns, with m , n , independently, being positive integers. Preferably, more than one column and more than one row is given, i.e. $n > 1$, $m > 1$. Thus, as an example, n may be 2 to 16 or higher and m may be 2 to 16 or higher. Preferably, the ratio of the number of rows and the number of columns is close to 1. As an example, n and m may be selected such that $0.3 \leq m/n \leq 3$, such as by choosing $m/n = 1:1$, $4:3$, $16:9$ or similar. As an example, the array may be a square array, having an equal number of rows and columns, such as by choosing $m=2$, $n=2$ or $m=3$, $n=3$ or the like.

The matrix specifically may be a rectangular matrix having at least one row, preferably a plurality of rows, and a plurality of columns. As an example, the rows and columns may be oriented essentially perpendicular, wherein, with respect to the term "essentially perpendicular", reference may be made to the definition given above. Thus, as an example, tolerances of less than 20°, specifically less than 10° or even less than 5°, may be acceptable. In order to provide a wide range of view, the matrix specifically may have at least 10 rows, preferably at least 50 rows, more preferably at least 100 rows. Similarly, the matrix may have at least 10 columns, preferably at least 50 columns, more preferably at least 100 columns. The matrix may comprise at least 50 optical sensors, preferably at least 100 optical sensors, more preferably at least 500 optical sensors. The matrix may comprise a number of pixels in a multi-mega pixel range. Other embodiments, however, are feasible. Thus, in setups in which an axial rotational symmetry is to be expected, circular arrangements or concentric arrangements of the optical sensors of the matrix, which may also be referred to as pixels, may be preferred.

Preferably, the sensor element may be oriented essentially perpendicular to an optical axis of the detector. Again, with respect to the term "essentially perpendicular", reference may be made to the definition and the tolerances given above. The optical axis may be a straight optical axis or may be bent or even split, such as by using one or more deflection elements and/or by using one or more beam splitters, wherein the essentially perpendicular orientation, in the latter cases, may refer to the local optical axis in the respective branch or beam path of the optical setup.

The reflection light beam may propagate from the object towards the detector. As will be outlined in further detail below, the reflection light beam may originate from the object or may originate from an illumination source, such as from an illumination source directly or indirectly illuminating the object, wherein the light beam is reflected or scattered by the object and, thereby, is at least partially directed towards the detector. The detector may be used in active and/or passive illumination scenarios. For example, the at least one illumination source may be adapted to illuminate the object, for example, by directing a light beam towards the object, which reflects the light beam. The illumination source may be or may comprise at least one multiple beam light source. For example, the illumination source may comprise at least one laser source and one or more diffractive optical elements (DOEs). Additionally or alternatively, the detector may use radiation already present in the scene such as from at least one ambient light source.

The reflection light beam specifically may fully illuminate the at least one optical sensor from which the center signal is generated, such that the at least one optical sensor from which the center signal arises is fully located within the light beam, with a width of the light beam being larger than the light-sensitive area of the at least one optical sensor from which the sensor signal arises. Contrarily, preferably, the reflection light beam specifically may create a light spot on the entire matrix which is smaller than the matrix, such that the light spot is fully located within the matrix. This situation may easily be adjusted by a person skilled in the art of optics by choosing one or more appropriate lenses or elements having a focusing or defocusing effect on the light beam, such as by using an appropriate transfer device as will be outlined in further de-

tail below. As further used herein, a “light spot” generally refers to a visible or detectable round or non-round illumination of an article, an area or object by a light beam.

As further used herein, a “sensor signal” generally refers to a signal generated by an optical sensor in response to the illumination by the light beam. Specifically, the sensor signal may be or may comprise at least one electrical signal, such as at least one analogue electrical signal and/or at least one digital electrical signal. More specifically, the sensor signal may be or may comprise at least one voltage signal and/or at least one current signal. More specifically, the sensor signal may comprise at least one photocurrent. Further, either raw sensor signals may be used, or the detector, the optical sensor or any other element may be adapted to process or preprocess the sensor signal, thereby generating secondary sensor signals, which may also be used as sensor signals, such as preprocessing by filtering or the like.

The light-sensitive areas specifically may be oriented towards the object. As used herein, the term “is oriented towards the object” generally refers to the situation that the respective surfaces of the light-sensitive areas are fully or partially visible from the object. Specifically, at least one interconnecting line between at least one point of the object and at least one point of the respective light-sensitive area may form an angle with a surface element of the light-sensitive area which is different from 0° , such as an angle in the range of 20° to 90° , preferably 80° to 90° such as 90° . Thus, when the object is located on the optical axis or close to the optical axis, the light beam propagating from the object towards the detector may be essentially parallel to the optical axis. As used herein, the term “essentially perpendicular” refers to the condition of a perpendicular orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less. Similarly, the term “essentially parallel” refers to the condition of a parallel orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less.

As used herein, the term “ray” generally refers to a line that is perpendicular to wavefronts of light which points in a direction of energy flow. As used herein, the term “beam” generally refers to a collection of rays. In the following, the terms “ray” and “beam” will be used as synonyms. As further used herein, the term “light beam” generally refers to an amount of light, specifically an amount of light traveling essentially in the same direction, including the possibility of the light beam having a spreading angle or widening angle. The light beam may have a spatial extension. Specifically, the light beam may have a non-Gaussian beam profile. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile. The trapezoid beam profile may have a plateau region and at least one edge region. The light beam specifically may be a Gaussian light beam or a linear combination of Gaussian light beams, as will be outlined in further detail below. Other embodiments are feasible, however. The transfer device may be configured for one or more of adjusting, defining and determining the beam profile, in particular a shape of the beam profile.

The optical sensors may be sensitive in one or more of the ultraviolet, the visible or the infrared spectral range. Specifically, the optical sensors may be sensitive in the visible spectral range

from 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm. Specifically, the optical sensors may be sensitive in the near infrared region. Specifically, the optical sensors may be sensitive in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm. The optical sensors, specifically, may
5 be sensitive in the infrared spectral range, specifically in the range of 780 nm to 3.0 micrometers. For example, the optical sensors each, independently, may be or may comprise at least one element selected from the group consisting of a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. For example, the optical sensors may be or may comprise at least one element selected from the group consisting of a CCD sensor element, a
10 CMOS sensor element, a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. Any other type of photosensitive element may be used. As will be outlined in further detail below, the photosensitive element generally may fully or partially be made of inorganic materials and/or may fully or partially be made of organic materials. Most commonly, as will be outlined in further detail below, one or more photodiodes may be used, such as com-
15 mercially available photodiodes, e.g. inorganic semiconductor photodiodes.

The detector may be adapted to determine at least one distance information of the object by using triangulation and/or structured light techniques. In known 3D sensing devices, such as
20 devices using triangulation or structured light techniques, due to correspondence problems regular, constant or periodic pattern are not suitable since each measured point has to be assigned to one reference point of a reference pattern.

As used herein, the term "reflection image" refers to an image determined by the optical sensor comprising at least one reflection feature. As used herein, the term "reflection feature" refers to
25 a feature in an image plane generated by the object in response to illumination, for example with at least one illumination feature. The reflection image may comprise the at least one reflection pattern comprising the at least one reflection feature. As used herein, the term "illumination feature" refers to at least one arbitrary shaped feature generated by at least one ambient light source or at least one illumination source adapted to illuminate the object. As used herein, the
30 term "determining at least one reflection image" refers to one or more of imaging, recording and generating of the reflection image. As used herein, the term "select at least one reflection feature" refers to one or more of identifying, determining and choosing at least one reflection feature of the reflection image. The detector may be adapted to determine the longitudinal coordinate of an object point for at least one reflection feature of the reflection image from the com-
35 bined signal. Thus, the detector may be adapted to pre-classify the at least one reflection feature of the reflection image. This allows using illumination patterns comprising regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that hexagonal patterns may be preferred.

40 The evaluation device may be adapted to perform at least one image analysis and/or image processing in order to identify the reflection feature. The image analysis and/or image processing may use at least one feature detection algorithm. The image analysis and/or image

processing may comprise one or more of the following: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency decomposition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be determined manually by a user or may be determined automatically, such as by recognizing an object within an image generated by the optical sensors.

The evaluation device is configured for determining at least one longitudinal region of the selected reflection feature of the reflection image by evaluating a combined signal Q from the sensor signals. The evaluation device may be adapted to determine at least one longitudinal coordinate z of the selected reflection feature by evaluating the combined signal Q, wherein the longitudinal region is given by the longitudinal coordinate z and an error interval $\pm \varepsilon$. As used herein, the term "longitudinal region" refers to at least one uncertainty interval defined by the longitudinal coordinate z and the measurement uncertainty $\pm \varepsilon$ of the determination of the longitudinal coordinate from the combined signal Q. Error ε may depend on measurement uncertainty of the optical sensor. The measurement uncertainty of the optical sensors may be pre-determined and/or estimated and/or may be deposited in at least one data storage unit of the evaluation device. For example, the error interval may be $\pm 10\%$, preferably $\pm 5\%$, more preferably $\pm 1\%$. As used herein, the term "combined signal Q" refers to a signal which is generated by combining the sensor signals, in particular by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals. The evaluation device may be configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals. The evaluation device may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal region for determining the longitudinal region. For example, the evaluation device may be configured for deriving the combined

$$\text{signal Q by } Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy},$$

wherein x and y are transversal coordinates, A1 and A2 are different areas of at least one beam profile of the reflection light beam at the sensor position, and $E(x, y, z_o)$ denotes the beam profile given at the object distance z_o . Area A1 and area A2 may differ. In particular, A1 and A2 are not congruent. Thus, A1 and A2 may differ in one or more of the shape or content. As used herein, the term "beam profile" relates to a spatial distribution, in particular in at least one plane per-

pendicular to the propagation of the light beam, of an intensity of the light beam. The beam profile may be a transverse intensity profile of the light beam. The beam profile may be a cross section of the light beam. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles. Generally the beam profile is dependent on luminance $L(z_0)$ and beam shape $S(x,y;z_0)$, $E(x,y;z_0)=L \cdot S$. Thus, by deriving the combined signal it may allow determining the longitudinal coordinate independent from luminance. In addition, using the combined signal allows determination of the distance z_0 independent from the object size. Thus, the combined signal allows determination of the distance z_0 independent from the material properties and/or reflective properties and/or scattering properties of the object and independent from alterations of the light source such as by manufacturing precision, heat, water, dirt, damages on the lens, or the like.

Each of the sensor signals may comprise at least one information of at least one area of the beam profile of the light beam. As used herein, the term "area of the beam profile" generally refers to an arbitrary region of the beam profile at the sensor position used for determining the combined signal Q . The light-sensitive areas may be arranged such that a first sensor signal comprises information of a first area of the beam profile and a second sensor signal comprises information of a second area of the beam profile. The first area of the beam profile and second area of the beam profile may be one or both of adjacent or overlapping regions. The first area of the beam profile and the second area of the beam profile may be not congruent in area.

The evaluation device may be configured to determine and/or to select the first area of the beam profile and the second area of the beam profile. The first area of the beam profile may comprise essentially edge information of the beam profile and the second area of the beam profile may comprise essentially center information of the beam profile. The beam profile may have a center, i.e. a maximum value of the beam profile and/or a center point of a plateau of the beam profile and/or a geometrical center of the light spot, and falling edges extending from the center. The second region may comprise inner regions of the cross section and the first region may comprise outer regions of the cross section. As used herein, the term "essentially center information" generally refers to a low proportion of edge information, i.e. proportion of the intensity distribution corresponding to edges, compared to a proportion of the center information, i.e. proportion of the intensity distribution corresponding to the center. Preferably the center information has a proportion of edge information of less than 10%, more preferably of less than 5%, most preferably the center information comprises no edge content. As used herein, the term "essentially edge information" generally refers to a low proportion of center information compared to a proportion of the edge information. The edge information may comprise information of the whole beam profile, in particular from center and edge regions. The edge information may have a proportion of center information of less than 10%, preferably of less than 5%, more preferably the edge information comprises no center content. At least one area of the beam profile may be determined and/or selected as second area of the beam profile if it is close or around the center and comprises essentially center information. At least one area of the beam profile may be determined and/or selected as first area of the beam profile if it comprises at least parts

of the falling edges of the cross section. For example, the whole area of the cross section may be determined as first region. The first area of the beam profile may be area A2 and the second area of the beam profile may be area A1.

- 5 Other selections of the first area A1 and second area A2 may be feasible. For example, the first area may comprise essentially outer regions of the beam profile and the second area may comprise essentially inner regions of the beam profile. For example, in case of a two-dimensional beam profile, the beam profile may be divided in a left part and a right part, wherein the first area may comprise essentially areas of the left part of the beam profile and the second area
10 may comprise essentially areas of the right part of the beam profile.

The edge information may comprise information relating to a number of photons in the first area of the beam profile and the center information may comprise information relating to a number of photons in the second area of the beam profile. The evaluation device may be adapted for determining an area integral of the beam profile. The evaluation device may be adapted to determine the edge information by integrating and/or summing of the first area. The evaluation device may be adapted to determine the center information by integrating and/or summing of the second area. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid. Further, when trapezoid beam
15 profiles may be assumed, the determination of edge and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

- 25 Additionally or alternatively, the evaluation device may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized, for example, by replacing the area integrals in the combined signal Q by a line integral along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or
30 cuts may result in improved distance information.

In one embodiment, the light beam propagating from the object to the detector may illuminate the sensor element with at least one pattern comprising at least one feature point. As used herein, the term "feature point" refers to at least one at least partially extended feature of the pattern. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors. The
35 central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

For example, the light beam propagating from the object to the detector may illuminate the optical sensors with at least one line pattern. The line pattern may be generated by the object, for example in response to an illumination by the at least one illumination source with an illumination pattern comprising the at least one line pattern. A1 may correspond to an area with a full line width of the line pattern on the optical sensors, in particular on the light sensitive area of the optical sensors. The line pattern on the optical sensors may be widened and/or displaced compared to the line pattern of the illumination pattern such that the line width on the optical sensors is increased. In particular, in case of a matrix of optical sensors, the line width of the line pattern on the optical sensors may change from one column to another column. A2 may be a central area of the line pattern on the optical sensors. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern may be segmented on the optical sensors. Each column of the matrix of optical sensors may comprise center information of intensity in the central area of the line pattern and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern.

For example, the light beam propagating from the object to the detector may illuminate the sensor element with at least one point pattern. The point pattern may be generated by the object, for example in response to an illumination by the at least one light source with an illumination pattern comprising the at least one point pattern. A1 may correspond to an area with a full radius of a point of the point pattern on the optical sensors. A2 may be a central area of the point in the point pattern on the optical sensors. The central area may be a constant value. The central area may have a radius compared to the full radius. For example, the central area may have a radius from 0.1 to 0.9 of the full radius, preferably from 0.4 to 0.6 of the full radius.

The light beam propagating from the object to the detector may illuminate the sensor element with a reflection pattern comprising both point patterns and line patterns. Other embodiments in addition or alternatively to line pattern and point pattern are feasible.

The evaluation device may be configured to derive the combined signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information. Thus, essentially, photon ratios may be used as the physical basis of the method.

For example, the evaluation device may be configured for evaluating the sensor signals, by

- a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
- b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;

- c) determining at least one combined signal by combining the center signal and the sum signal; and
- d) determining the at least one longitudinal coordinate z of the selected feature by evaluating the combined signal.

5

As explained, e.g. in WO 2012/110924 A1 or WO 2014/097181 A1, typically, a predetermined or determinable relationship exists between a size of a light spot, such as a diameter of the light spot, a beam waist or an equivalent diameter, and the longitudinal coordinate of the object from which the light beam propagates towards the detector. Without wishing to be bound by this theory, the light spot may be characterized by two measurement variables: a measurement signal measured in a small measurement patch in the center or close to the center of the light spot, also referred to as the center signal, and an integral or sum signal integrated over the light spot, with or without the center signal. For a light beam having a certain total power which does not change when the beam is widened or focused, the sum signal should be independent from the spot size of the light spot, and, thus, should, at least when linear optical sensors within their respective measurement range are used, be independent from the distance between the object and the detector. The center signal, however, is dependent on the spot size. Thus, the center signal typically increases when the light beam is focused, and decreases when the light beam is defocused. By comparing the center signal and the sum signal, thus, an item of information on the size of the light spot generated by the light beam and, thus, on the longitudinal coordinate of the object may be generated. The comparing of the center signal and the sum signal, as an example, may be done by forming the combined signal Q out of the center signal and the sum signal and by using a predetermined or determinable relationship between the longitudinal coordinate and the quotient signal for deriving the longitudinal coordinate.

25

The use of a matrix of optical sensors provides a plurality of advantages and benefits. Thus, the center of the light spot generated by the light beam on the sensor element, such as on the common plane of the light-sensitive areas of the optical sensors of the matrix of the sensor element, may vary with a transversal position of the object. By using a matrix of optical sensors, the detector according to the present invention may adapt to these changes in conditions and, thus, may determine the center of the light spot simply by comparing the sensor signals. Consequently, the detector according to the present invention may, by itself, choose the center signal and determine the sum signal and, from these two signals, derive a combined signal which contains information on the longitudinal coordinate of the object. By evaluating the combined signal, the longitudinal coordinate of the object may, thus, be determined. The use of the matrix of optical sensors, thus, provides a significant flexibility in terms of the position of the object, specifically in terms of a transversal position of the object.

35

The transversal position of the light spot on the matrix of optical sensors, such as the transversal position of the at least one optical sensor generating the sensor signal, may even be used as an additional item of information, from which at least one item of information on a transversal position of the object may be derived, as e.g. disclosed in WO 2014/198629 A1. Additionally or alternatively, as will be outlined in further detail below, the detector according to the present

40

invention may contain at least one additional transversal detector for, in addition to the at least one longitudinal coordinate, detecting at least one transversal coordinate of the object.

Consequently, in accordance with the present invention, the term "center signal" generally refers to the at least one sensor signal comprising essentially center information of the beam profile. For example, the center signal may be the signal of the at least one optical sensor having the highest sensor signal out of the plurality of sensor signals generated by the optical sensors of the entire matrix or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable within an image generated by the optical sensors of the matrix. As used herein, the term "highest sensor signal" refers to one or both of a local maximum or a maximum in a region of interest. The center signal may arise from a single optical sensor or, as will be outlined in further detail below, from a group of optical sensors, wherein, in the latter case, as an example, the sensor signals of the group of optical sensors may be added up, integrated or averaged, in order to determine the center signal. The group of optical sensors from which the center signal arises may be a group of neighboring optical sensors, such as optical sensors having less than a predetermined distance from the actual optical sensor having the highest sensor signal, or may be a group of optical sensors generating sensor signals being within a predetermined range from the highest sensor signal. The group of optical sensors from which the center signal arises may be chosen as large as possible in order to allow maximum dynamic range. The evaluation device may be adapted to determine the center signal by integration of the plurality of sensor signals, for example the plurality of optical sensors around the optical sensor having the highest sensor signal. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid, in particular of a plateau of the trapezoid.

As outlined above, the center signal generally may be a single sensor signal, such as a sensor signal from the optical sensor in the center of the light spot, or may be a combination of a plurality of sensor signals, such as a combination of sensor signals arising from optical sensors in the center of the light spot, or a secondary sensor signal derived by processing a sensor signal derived by one or more of the aforementioned possibilities. The determination of the center signal may be performed electronically, since a comparison of sensor signals is fairly simply implemented by conventional electronics, or may be performed fully or partially by software. Specifically, the center signal may be selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; an in-

tegral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

- 5 Similarly, the term "sum signal" generally refers to a signal comprising essentially edge information of the beam profile. For example, the sum signal may be derived by adding up the sensor signals, integrating over the sensor signals or averaging over the sensor signals of the entire matrix or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable within an image generated by the optical sensors of the matrix.
- 10 When adding up, integrating over or averaging over the sensor signals, the actual optical sensors from which the sensor signal is generated may be left out of the adding, integration or averaging or, alternatively, may be included into the adding, integration or averaging. The evaluation device may be adapted to determine the sum signal by integrating signals of the entire matrix, or of the region of interest within the matrix. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the entire trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of
- 15 edge and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.
- 20

Similarly, the center signal and edge signal may also be determined by using segments of the beam profile such as circular segments of the beam profile. For example, the beam profile may be divided into two segments by a secant or a chord that does not pass the center of the beam profile. Thus, one segment will essentially contain edge information, while the other segment

25 will contain essentially center information. For example, to further reduce the amount of edge information in the center signal, the edge signal may further be subtracted from the center signal.

- 30 Additionally or alternatively, the evaluation device may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized for example by replacing the area integrals in the combined signal Q by a line integral along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or
- 35 cuts may result in an improved distance information.

The combined signal may be a signal which is generated by combining the center signal and the sum signal. Specifically, the combination may include one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa. Additionally or alternatively, the combined signal may comprise an arbitrary signal or signal combination which

40

contains at least one item of information on a comparison between the center signal and the sum signal.

The evaluation device may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between the sensor signals. In particular, the evaluation device is configured to determine the at least one coordinate z of the object by using at least one known, determinable or predetermined relationship between a quotient signal derived from the sensor signals and the longitudinal coordinate.

Raw sensor signals of the optical sensors may be used for evaluation or secondary sensor signals derived thereof. As used herein, the term "secondary sensor signal" generally refers to a signal, such as an electronic signal, more preferably an analogue and/or a digital signal, which is obtained by processing one or more raw signals, such as by filtering, averaging, demodulating or the like. Thus, image processing algorithms may be used for generating secondary sensor signals from the totality of sensor signals of the matrix or from a region of interest within the matrix. Specifically, the detector, such as the evaluation device, may be configured for transforming the sensor signals of the optical sensor, thereby generating secondary optical sensor signals, wherein the evaluation device is configured for performing steps a)-d) by using the secondary optical sensor signals. The transformation of the sensor signals specifically may comprise at least one transformation selected from the group consisting of: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency decomposition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be determined manually by a user or may be determined automatically, such as by recognizing an object within an image generated by the optical sensors. As an example, a vehicle, a person or another type of predetermined object may be determined by automatic image recognition within an image, i.e. within the totality of sensor signals generated by the optical sensors, and the region of interest may be chosen such that the object is located within the region of interest. In this case, the evaluation, such as the determination of the longitudinal coordinate, may be performed for the region of interest, only. Other implementations, however, are feasible.

As outlined above, the detection of the center of the light spot, i.e. the detection of the center signal and/or of the at least one optical sensor from which the center signal arises, may be per-

formed fully or partially electronically or fully or partially by using one or more software algorithms. Specifically, the evaluation device may comprise at least one center detector for detecting the at least one highest sensor signal and/or for forming the center signal. The center detector specifically may fully or partially be embodied in software and/or may fully or partially be embodied in hardware. The center detector may fully or partially be integrated into the at least one sensor element and/or may fully or partially be embodied independently from the sensor element.

As outlined above, the sum signal may be derived from all sensor signals of the matrix, from the sensor signals within a region of interest or from one of these possibilities with the sensor signals arising from the optical sensors contributing to the center signal excluded. In every case, a reliable sum signal may be generated which may be compared with the center signal reliably, in order to determine the longitudinal coordinate. Generally, the sum signal may be selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; an integral of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal. Other options, however, exist.

The summing may be performed fully or partially in software and/or may be performed fully or partially in hardware. A summing is generally possible by purely electronic means which, typically, may easily be implemented into the detector. Thus, in the art of electronics, summing devices are generally known for summing two or more electrical signals, both analogue signals and digital signals. Thus, the evaluation device may comprise at least one summing device for forming the sum signal. The summing device may fully or partially be integrated into the sensor element or may fully or partially be embodied independently from the sensor element. The summing device may fully or partially be embodied in one or both of hardware or software.

As outlined above, the comparison between the center signal and the sum signal specifically may be performed by forming one or more quotient signals. Thus, generally, the combined signal may be a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of the center signal and a linear combination of the sum signal and the center signal or vice versa; forming a

quotient of the sum signal and a linear combination of the sum signal and the center signal or vice versa; forming a quotient of an exponentiation of the center signal and an exponentiation of the sum signal or vice versa. Other options, however, exist. The evaluation device may be configured for forming the one or more quotient signals. The evaluation device may further be configured for determining the at least one longitudinal coordinate by evaluating the at least one quotient signal.

The evaluation device specifically may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal coordinate, in order to determine the at least one longitudinal coordinate. Thus, due to the reasons disclosed above and due to the dependency of the properties of the light spot on the longitudinal coordinate, the combined signal Q typically is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, a simple quotient of the sensor signal s_{center} and the sum signal s_{sum} $Q = s_{\text{center}}/s_{\text{sum}}$ may be a monotonously decreasing function of the distance. Without wishing to be bound by this theory, it is believed that this is due to the fact that, in the preferred setup described above, both the center signal s_{center} and the sum signal s_{sum} decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, the center signal s_{center} decreases more rapidly than the sum signal s_{sum} , since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. The quotient of the center signal and the sum signal, thus, continuously decreases with increasing diameter of the light beam or diameter of the light spot on the light-sensitive areas of the optical sensors of the matrix. The quotient, further, is typically independent from the total power of the light beam, since the total power of the light beam forms a factor both in the center signal and in the sum sensor signal. Consequently, the combined signal Q may form a secondary signal which provides a unique and unambiguous relationship between the center signal and the sum signal and the size or diameter of the light beam. Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship between the center signal and the sum signal on the one hand and the longitudinal coordinate on the other hand may exist. For the latter, reference e.g. may be made to one or more of the above-mentioned prior art documents, such as WO 2014/097181 A1. The predetermined relationship may be determined by analytical considerations, such as by assuming a linear combination of Gaussian light beams, by empirical measurements, such as measurements measuring the combined signal and/or the center signal and the sum signal or secondary signals derived thereof as a function of the longitudinal coordinate of the object, or both.

Thus, generally, the evaluation device may be configured for determining the longitudinal coordinate by evaluating the combined signal Q . This determining may be a one-step process, such as by directly combining the center signal and the sum signal and deriving the longitudinal coordinate thereof, or may be a multiple step process, such as by firstly deriving the combined sig-

nal from the center signal and the sum signal and, secondly, by deriving the longitudinal coordinate from the combined signal. Both options, i.e. the option of steps c) and d) being separate and independent steps and the option of steps c) and d) being fully or partially combined, shall be comprised by the present invention.

5

The evaluation device may be configured for using at least one predetermined relationship between the combined signal and the longitudinal coordinate. The predetermined relationship may be one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship. The evaluation device may comprise at least one data storage device for storing the predetermined relationship, such as a lookup list or a lookup table.

10

The combined signal Q may be determined by using various means. As an example, a software means for deriving the quotient signal, a hardware means for deriving the quotient signal, or both, may be used and may be implemented in the evaluation device. Thus, the evaluation device, as an example, may comprise at least one divider, wherein the divider is configured for deriving the quotient signal. The divider may fully or partially be embodied as one or both of a software divider or a hardware divider. The divider may fully or partially be integrated into the sensor element answers or may fully or partially be embodied independent from the sensor element.

15

20

The detector may comprise at least one optical element selected from the group consisting of: transfer device, such as at least one lens and/or at least one lens system, at least one diffractive optical element. The term "transfer device", also denoted as "transfer system", may generally refer to one or more optical elements which are adapted to modify the light beam, such as by modifying one or more of a beam parameter of the light beam, a width of the light beam or a direction of the light beam. The transfer device may be adapted to guide the light beam onto the optical sensors. The transfer device specifically may comprise one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system. As used herein, the term "focal length" of the transfer device refers to a distance over which incident collimated rays which may impinge the transfer device are brought into a "focus" which may also be denoted as "focal point". Thus, the focal length constitutes a measure of an ability of the transfer device to converge an impinging light beam. Thus, the transfer device may comprise one or more imaging elements which can have the effect of a converging lens. By way of example, the transfer device can have one or more lenses, in particular one or more refractive lenses, and/or one or more convex mirrors. In this example, the focal length may be defined as a distance from the center of the thin refractive lens to the principal focal points of the thin lens. For a converging thin refractive lens, such as a convex or biconvex thin lens, the focal length may be considered as being positive and may provide the distance at which a beam of collimated light impinging the thin lens as the transfer device may be focused into a single spot. Additionally, the transfer

25

30

35

40

device can comprise at least one wavelength-selective element, for example at least one optical filter. Additionally, the transfer device can be designed to impress a predefined beam profile on the electromagnetic radiation, for example, at the location of the sensor region and in particular the sensor area. The abovementioned optional embodiments of the transfer device can, in principle, be realized individually or in any desired combination.

The transfer device may have an optical axis. In particular, the detector and the transfer device have a common optical axis. As used herein, the term "optical axis of the transfer device" generally refers to an axis of mirror symmetry or rotational symmetry of the lens or lens system. The optical axis of the detector may be a line of symmetry of the optical setup of the detector. The detector comprises at least one transfer device, preferably at least one transfer system having at least one lens. The transfer system, as an example, may comprise at least one beam path, with the elements of the transfer system in the beam path being located in a rotationally symmetrical fashion with respect to the optical axis. Still, as will also be outlined in further detail below, one or more optical elements located within the beam path may also be off-centered or tilted with respect to the optical axis. In this case, however, the optical axis may be defined sequentially, such as by interconnecting the centers of the optical elements in the beam path, e.g. by interconnecting the centers of the lenses, wherein, in this context, the optical sensors are not counted as optical elements. The optical axis generally may denote the beam path. Therein, the detector may have a single beam path along which a light beam may travel from the object to the optical sensors, or may have a plurality of beam paths. As an example, a single beam path may be given or the beam path may be split into two or more partial beam paths. In the latter case, each partial beam path may have its own optical axis. The optical sensors may be located in one and the same beam path or partial beam path. Alternatively, however, the optical sensors may also be located in different partial beam paths.

The transfer device may constitute a coordinate system, wherein a longitudinal coordinate l is a coordinate along the optical axis and wherein d is a spatial offset from the optical axis. The coordinate system may be a polar coordinate system in which the optical axis of the transfer device forms a z -axis and in which a distance from the z -axis and a polar angle may be used as additional coordinates. A direction parallel or antiparallel to the z -axis may be considered a longitudinal direction, and a coordinate along the z -axis may be considered a longitudinal coordinate l . Any direction perpendicular to the z -axis may be considered a transversal direction, and the polar coordinate and/or the polar angle may be considered a transversal coordinate.

As further used herein, the term "evaluation device" generally refers to an arbitrary device adapted to perform the named operations, preferably by using at least one data processing device and, more preferably, by using at least one processor and/or at least one application-specific integrated circuit. Thus, as an example, the at least one evaluation device may comprise at least one data processing device having a software code stored thereon comprising a number of computer commands. The evaluation device may provide one or more hardware elements for performing one or more of the named operations and/or may provide one or more processors with software running thereon for performing one or more of the named operations.

The above-mentioned operations, including determining the at least one longitudinal coordinate of the object, are performed by the at least one evaluation device. Thus, as an example, one or more of the above-mentioned relationships may be implemented in software and/or hardware, such as by implementing one or more lookup tables. Thus, as an example, the evaluation device may comprise one or more programmable devices such as one or more computers, application-specific integrated circuits (ASICs), Digital Signal Processors (DSPs), or Field Programmable Gate Arrays (FPGAs) which are configured to perform the above-mentioned evaluation, in order to determine the at least one longitudinal coordinate of the object. Additionally or alternatively, however, the evaluation device may also fully or partially be embodied by hardware.

As outlined above, by evaluating the center signal and the sum signal, the detector may be enabled to determine the at least one longitudinal coordinate of the object, including the option of determining the longitudinal coordinate of the whole object or of one or more parts thereof. In addition, however, other coordinates of the object, including one or more transversal coordinates and/or rotational coordinates, may be determined by the detector, specifically by the evaluation device. Thus, as an example, one or more transversal sensors may be used for determining at least one transversal coordinate of the object. As outlined above, the position of the at least one optical sensor from which the center signal arises may provide information on the at least one transversal coordinate of the object, wherein, as an example, a simple lens equation may be used for optical transformation and for deriving the transversal coordinate. Additionally or alternatively, one or more additional transversal sensors may be used and may be comprised by the detector. Various transversal sensors are generally known in the art, such as the transversal sensors disclosed in WO 2014/097181 A1 and/or other position-sensitive devices (PSDs), such as quadrant diodes, CCD or CMOS chips or the like. Additionally or alternatively, as an example, the detector according to the present invention may comprise one or more PSDs disclosed in R.A. Street (Ed.): *Technology and Applications of Amorphous Silicon*, Springer-Verlag Heidelberg, 2010, pp. 346-349. Other embodiments are feasible. These devices may generally also be implemented into the detector according to the present invention. As an example, a part of the light beam may be split off within the detector, by at least one beam splitting element. The split-off portion, as an example, may be guided towards a transversal sensor, such as a CCD or CMOS chip or a camera sensor, and a transversal position of a light spot generated by the split-off portion on the transversal sensor may be determined, thereby determining at least one transversal coordinate of the object. Consequently, the detector according to the present invention may either be a one-dimensional detector, such as a simple distance measurement device, or may be embodied as a two-dimensional detector or even as a three-dimensional detector. Further, as outlined above or as outlined in further detail below, by scanning a scenery or an environment in a one-dimensional fashion, a three-dimensional image may also be created. Consequently, the detector according to the present invention specifically may be one of a one-dimensional detector, a two-dimensional detector or a three-dimensional detector. The evaluation device may further be configured to determine at least one transversal coordinate x , y of the object. The evaluation device may be adapted to combine the information

of the longitudinal coordinate and the transversal coordinate and to determine a position of the object in space.

As outlined above, the evaluation device is adapted to determine at least one displacement region in at least one reference image corresponding to the longitudinal region. As used herein, the term "reference image" refers to an image different from the reflection image which is determined at a different spatial position compared to the reflection image. The reference image may be determined by one or more of recording at least one reference feature, imaging the at least one reference feature, calculating of the reference image. The reference image and the reflection image may be images of the object determined at different spatial positions having a fixed distance. The distance may be a relative distance, also called baseline. The evaluation device may be adapted to determine the at least one reference feature in the at least one reference image corresponding to the at least one reflection feature. As outlined above, the evaluation device may be adapted to perform an image analysis and to identify features of the reflection image. The evaluation device may be adapted to identify at least one reference feature in the reference image having an essentially identical longitudinal coordinate as the selected reflection feature. The term "essentially identical" refers to identical within 10%, preferably 5%, most preferably 1%. The reference feature corresponding to the reflection feature may be determined using epipolar geometry. For description of epipolar geometry reference is made, for example, to chapter 2 in X. Jiang, H. Bunke: „Dreidimensionales Computersehen“ Springer, Berlin Heidelberg, 1997. Epipolar geometry may assume that the reference image and the reflection image may be images of the object determined at different spatial positions and/or spatial orientations having a fixed distance. The evaluation device may be adapted to determine an epipolar line in the reference image. Relative position of the reference image and reflection image may be known. For example, relative position of the reference image and reflection image may be stored within at least one storage unit of the evaluation device. The evaluation device may be adapted to determine a straight line extending from the selected reflection feature of the reflection image. The straight line may comprise possible object features corresponding to the selected feature. The straight line and the baseline span an epipolar plane. As the reference image is determined at a different relative position from the reflection image, the corresponding possible object features may be imaged on a straight line, called epipolar line, in the reference image. Thus, a feature of the reference image corresponding to the selected feature of the reflection image lies on the epipolar line. Due to distortions of the image or changes in the system parameters such as due to ageing, temperature changes, mechanical stress or the like, epipolar lines may intersect or be very close to each other and/or the correspondence between reference feature and reflection feature may be unclear. Further, each known position or object in the real world may be projected onto the reference image and vice versa. The projection may be known due to a calibration of the detector, whereas the calibration is comparable to a teaching of the epipolar geometry of the specific camera.

40

As used herein, the term "displacement region" refers to a region in the reference image in which the reference feature corresponding to the selected reflection feature may be imaged. Specifically, the displacement region may be a region in the reference image in which the refer-

ence feature corresponding to the selected reflection feature is expected to be located in the reference image. Depending on the distance to the object, an image position of the reference feature corresponding to the reflection feature may be displaced within the reference image compared to an image position of the reflection feature in the reflection image. The displacement region may comprise only one reference feature. The displacement region may also comprise more than one reference feature. The displacement region may comprise an epipolar line or a section of an epipolar line. The displacement region may comprise more than one epipolar line or more sections of more than one epipolar line. As used herein, the term "reference feature" refers to at least one feature of the reference image. The displacement region may extend along the epipolar line, orthogonal to an epipolar line, or both. The evaluation device may be adapted to determine the reference feature along the epipolar line corresponding to the longitudinal coordinate z and to determine an extent of the displacement region along the epipolar line corresponding to the error interval $\pm \varepsilon$ or orthogonal to an epipolar line. The measurement uncertainty of the distance measurement using the combined signal Q may result in a displacement region which is non-circular since the measurement uncertainty may be different for different directions. Specifically, the measurement uncertainty along the epipolar line or epipolar lines may be greater than the measurement uncertainty in an orthogonal direction with respect to the epipolar line or epipolar lines. The displacement region may comprise an extend in an orthogonal direction with respect to the epipolar line or epipolar lines. The evaluation device may determine a displacement region around the image position of the reflection feature. The evaluation device may be adapted to determine the longitudinal coordinate z for the reflection feature and an error interval $\pm \varepsilon$ from the combined signal Q to determine the displacement region along the epipolar line corresponding to $z \pm \varepsilon$. The evaluation device is adapted to match the selected reflection feature with at least one reference feature within the displacement region. As used herein, the term "matching" refers to determining and/or evaluating corresponding reference and reflection features. The evaluation device may be adapted to match the selected feature of the reflection image with the reference feature within the displacement region by using at least one evaluation algorithm considering the determined longitudinal coordinate z . The evaluation algorithm may be a linear scaling algorithm. The evaluation device may be adapted to determine the epipolar line closest to and/or within the displacement region. The evaluation device may be adapted to determine the epipolar line closest to the image position of the reflection feature. The extent of the displacement region along the epipolar line may be larger than the extent of the displacement region orthogonal to the epipolar line. The evaluation device may be adapted to determine an epipolar line before determining a corresponding reference feature. The evaluation device may determine a displacement region around the image position of each reflection feature. The evaluation device may be adapted to assign an epipolar line to each displacement region of each image position of the reflection features, such as by assigning the epipolar line closest to a displacement region and/or within a displacement region and/or closest to a displacement region along a direction orthogonal to the epipolar line. The evaluation device may be adapted to determine the reference feature corresponding to the image position of the reflection feature by determining the reference feature closest to the assigned displacement region and/or within the assigned displacement region and/or closest to the assigned displacement

region along the assigned epipolar line and/or within the assigned displacement region along the assigned epipolar line.

Additionally or alternatively, the evaluation device may be configured to perform the following steps:

- 5 - Determining the displacement region for the image position of each reflection feature;
- Assigning an epipolar line to the displacement region of each reflection feature such as by assigning the epipolar line closest to a displacement region and/or within a displacement region and/or closest to a displacement region along a direction orthogonal to the epipolar line;
- 10 - Assigning and/or determining at least one reference feature to each reflection feature such as by assigning the reference feature closest to the assigned displacement region and/or within the assigned displacement region and/or closest to the assigned displacement region along the assigned epipolar line and/or within the assigned displacement region along the assigned epipolar line.

- 15 Additionally or alternatively, the evaluation device may be adapted to decide between more than one epipolar line and/or reference feature to be assigned to a reflection feature such as by comparing distances of reflection features and/or epipolar lines within the reference image and/or by comparing error weighted distances, such as ϵ -weighted distances of reflection features and/or epipolar lines within the reference image and assigning the epipolar line and/or
- 20 reference feature in shorter distance and/or ϵ -weighted distance to the reference feature and/or reflection feature.

- Preferably, the detector may be adapted to pre-classify the selected reflection feature using the combined signal Q such that an unambiguous assignment to one reference feature is possible. In particular, illumination features of the illumination pattern may be arranged such that corresponding reference features of the reference image may have a relative distance to each other as large as possible on the epipolar line. The illumination features of the illumination pattern may be arranged such that only few reference features are positioned on the epipolar line. For example, the illumination pattern may comprise at least one hexagonal pattern. Preferably, the illumination pattern may comprise at least one hexagonal pattern, wherein the pattern is rotated relative to the baseline. Preferably, the illumination pattern may comprise at least one displaced hexagonal pattern, wherein individual points of the hexagonal pattern are displaced by a random distance from the regular position, for example orthogonal to the epipolar line of the point.
- 30 The displacement of the individual points may be smaller than half of the distance between two parallel epipolar lines, preferably smaller than one fourth of the distance between two parallel epipolar lines. The displacement of the individual points may be as such that two points are not displaced above each other.

- 40 The evaluation device may be adapted to determine a displacement of the matched reference feature and the selected reflection feature. As used herein, the term "displacement" refers to difference between a position in the reference image to a position in the reflection image. The evaluation device may be adapted to determine a longitudinal information of the matched fea-

ture using a predetermined relationship between a longitudinal coordinate and the displacement. As used herein, the term "longitudinal information" refers to information relating to the longitudinal coordinate. For example, the longitudinal information may be a distance value. The evaluation device may be adapted to determine the pre-determined relationship by using triangulation methods. In case position of the selected reflection feature in the reflection image and position of the matched reference feature and/or relative displacement of the selected reflection feature and the matched reference feature are known, longitudinal coordinate of the corresponding object feature may be determined by triangulation. Thus, the evaluation device may be adapted to select, for example subsequent and/or column by column, a reflection feature and to determine for each potential position of the reference feature the corresponding distance value using triangulation. Displacement and corresponding distance value may be stored in at least one storage device of the evaluation device. The evaluation device may, as an example, comprise at least one data processing device, such as at least one processor, at least one DSP, at least one FPGA and/or at least one ASIC. Further, for storing the at least one predetermined or determinable relationship between the longitudinal coordinate z and the displacement, the at least one data storage device may be provided, such as for providing one or more look-up tables for storing the predetermined relationship. The evaluation device may be adapted to store parameters for an intrinsic and/or extrinsic calibration of the camera and/or the detector. The evaluation device may be adapted to generate the parameters for an intrinsic and/or extrinsic calibration of the camera and/or the detector such as by performing a Tsai camera calibration. The evaluation device may be adapted to compute and/or estimate parameters such as the focal length of the transfer device, the radial lens distortion coefficient, the coordinates of the center of radial lens distortion, scale factors to account for any uncertainty due to imperfections in hardware timing for scanning and digitization, rotation angles for the transformation between the world and camera coordinates, translation components for the transformation between the world and camera coordinates, aperture angles, image sensor format, principal point, skew coefficients, camera center, camera heading, baseline, rotation or translation parameters between camera and/or illumination source, apertures, focal distance, or the like.

Using the combined sensor signal allows to estimate distances, such as the longitudinal coordinate z within the error interval. By determining the displacement region corresponding to the estimated longitudinal coordinate and the corresponding error interval allows to reduce the possible number of solutions along the epipolar line significantly. The number of possible solutions may even be reduced to one. Determining of the longitudinal coordinate z and the error interval may be performed during a pre-evaluation before matching the selected reflection feature and reference feature. This may allow reducing the computational demand such that it is possible to significantly reduce costs and to allow a use in mobile device or outdoor devices. Furthermore, generally in triangulation systems the baseline has to be large in order to detect large distances. Pre-evaluation of the longitudinal coordinate z and error interval using the combined sensor signal and subsequent matching of the selected reflection feature and reference feature may allow using short baselines such that it may be possible to provide a compact device. Furthermore, pre-evaluation of the longitudinal coordinate z and error interval using the combined sensor signal and subsequent matching of the selected reflection feature and reference feature

may enhance accuracy and/or speed and/or may lower computational demand in comparison to conventional triangulation systems. Further, the number of illumination features such as the number of illumination points in the illumination pattern may be reduced to increase the light intensity in each illumination point such as to compete with ambient light while complying to eye safety regulations. A reduced number of illumination features in a conventional triangulation system might increase the difficulty to match reflection features and reference features. Further, the number of illumination features such as the number of illumination points in the illumination pattern may be increased, such as to increase the resolution of the distance measurement, such as to increase the resolution of the obtained depth map without increasing the processing power of the evaluation device such as in a mobile application.

The detector may further comprise an illumination source. As an example, the illumination source may be configured for generating an illuminating light beam for illuminating the object. The detector may be configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector. For this purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

The illumination source may be adapted to generate at least one illumination pattern for illumination of the object. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. The detector may be configured such that the illumination pattern propagates from the detector, in particular from at least one opening of the housing, towards the object along and/or parallel to an optical axis of the detector. For this purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illumination pattern such that it propagates along or parallel to the optical axis. Specifically, the illumination source may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. As used herein, the term "pattern" refers to an arbitrary known or pre-determined arrangement comprising at least one arbitrarily shaped feature. The pattern may comprise at least one feature such as a point or symbol. The pattern may comprise a plurality of features. The pattern may comprise an arrangement of periodic or non-periodic features. As used herein, the term "illumination pattern" refers to a pattern which illuminates the object. The illumination pattern may be generated by ambient light, such as by at least one ambient light source, or by the at least one illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern; a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines. For example, the illumination source may be adapted to generate and/or to project a cloud of points. The illumination pattern may comprise regular and/or constant and/or periodic pattern

such as a triangular pattern, a rectangular pattern, a hexagonal pattern, or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that a hexagonal pattern may be preferred. A distance between two features of the illumination pattern and/or an area of the at least one illumination feature may depend on the circle of confusion in the image.

The illumination source may comprise one or more of at least one light projector; at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The illumination source may comprise at least one light source adapted to generate the illumination pattern directly. For example, the illumination source may comprise at least one laser source. For example, the illumination source may comprise at least one line laser. The line laser may be adapted to send a laser line to the object, for example a horizontal or vertical laser line. The illumination source may comprise a plurality of line lasers. For example, the illumination source may comprise at least two line lasers which may be arranged such that the illumination pattern comprises at least two parallel or crossing lines. The illumination source may comprise the at least one light projector adapted to generate a cloud of points such that the illumination pattern may comprise a plurality of point pattern. The illumination source may comprise at least one mask adapted to generate the illumination pattern from at least one light beam generated by the illumination source. The illumination source may be one of attached to or integrated into a mobile device such as a smartphone. The illumination source may be used for further functions that may be used in determining an image such as for an autofocus function. The illumination device may be attached to a mobile device such as by using a connector such as a USB- or phone-connector such as the headphone jack.

The illumination source, specifically, may be configured for emitting light in the infrared spectral range. It shall be noted, however, that other spectral ranges are feasible, additionally or alternatively. Further, the illumination source specifically may be configured for emitting modulated or non-modulated light. In case a plurality of illumination sources is used, the different illumination sources may have different modulation frequencies which, as outlined in further detail below, later on may be used for distinguishing the light beams. The detector may be configured for evaluating a single light beam or a plurality of light beams. In case a plurality of light beams propagates from the object to the detector, means for distinguishing the light beams may be provided. Thus, the light beams may have different spectral properties, and the detector may comprise one or more wavelength selective elements for distinguishing the different light beams. Each of the light beams may then be evaluated independently. The wavelength selective elements, as an example, may be or may comprise one or more filters, one or more prisms, one or more gratings, one or more dichroitic mirrors or arbitrary combinations thereof. Further, additionally or alternatively, for distinguishing two or more light beams, the light beams may be modulated in a specific fashion. Thus, as an example, the light beams may be frequency modulated, and the sensor signals may be demodulated in order to distinguish partially the sensor signals originating from the different light beams, in accordance with their demodulation frequencies. These techniques generally are known to the skilled person in the field of high-

frequency electronics. Generally, the evaluation device may be configured for distinguishing different light beams having different modulations.

Specifically, the illumination source and the optical sensors may be arranged in a common plane or in different planes. The illumination source and the optical sensors may have different spatial orientation. In particular, the illumination source and the sensor element may be arranged in a twisted arrangement.

The illumination source may be adapted to generate and/or to project a cloud of points such that a plurality of illuminated regions is generated on the matrix of optical sensors, for example the CMOS detector. Additionally, disturbances may be present on the matrix of optical sensors such as disturbances due to speckles and/or extraneous light and/or multiple reflections. The evaluation device may be adapted to determine at least one region of interest, for example one or more pixels illuminated by the light beam which are used for determination of the longitudinal coordinate of the object. For example, the evaluation device may be adapted to perform a filtering method, for example, a blob-analysis and/or an edge filter and/or object recognition method.

The sensor element may be adapted to determine at least one reflection pattern. As used herein, the term "reflection pattern" refers to a response pattern generated by reflection or scattering of light at the surface of the object, in particular generated by the object in response to illumination by the illumination pattern. As outlined above, the illumination pattern comprises at least one feature adapted to illuminate the object. As outlined above, the illumination feature may be generated by ambient light or by the at least one illumination source. The reflection pattern may comprise at least one feature corresponding to at least one feature of the illumination pattern.

The reflection pattern may comprise, in comparison to the illumination pattern, at least one distorted pattern, wherein the distortion depends on the distance of the object, such as surface properties of the object. The evaluation device may be adapted to select at least one feature of the reflection pattern and to determine the longitudinal region of the selected feature of the reflection pattern by evaluating the combined signal Q from the sensor signals, as described above.

For example, the reference image may be an image of the illumination pattern at an image plane at a position of the illumination source. The evaluation device may be adapted to determine the displacement region in the reference image corresponding to the longitudinal region of the selected feature of the reflection pattern. The evaluation device may be adapted to match the selected feature of the reflection pattern with at least one feature of the reference pattern within the displacement region. The illumination source and the sensor element may be separated by a fixed distance.

For example, the detector may comprise at least two sensor elements each having a matrix of optical sensors. At least one first sensor element and at least one second sensor element may be positioned at different spatial positions. A relative distance between the first sensor element and the second element may be fixed. The at least one first sensor element may be adapted to

- determine at least one first reflection pattern, in particular at least one first reflection feature, and the at least one second sensor element may be adapted to determine at least one second reflection pattern, in particular at least one second reflection feature. The evaluation device may be adapted to select at least one image determined by the first sensor element or the second sensor element as reflection image and to select at least one image determined by the other one of the first sensor element or the second sensor element as reference image. The evaluation device may be adapted to select the at least one reflection feature in the reflection pattern and to determine the longitudinal region of the selected feature by evaluating the combined signal Q from the sensor signals. The evaluation device may be adapted to determine the displacement region in the reference image corresponding to the longitudinal region of the selected feature of the reflection pattern. The evaluation device may be adapted to match the selected feature of the reflection pattern with at least one feature of the reference pattern within the displacement region.
- 15 As outlined above, the detector may further comprise one or more additional elements such as one or more additional optical elements. Further, the detector may fully or partially be integrated into at least one housing.

- In a further aspect of the present invention, a detector system for determining a position of at least one object is disclosed. The detector system comprises at least one detector according to the present invention, such as according to one or more of the embodiments disclosed above or according to one or more of the embodiments disclosed in further detail below. The detector system further comprises at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object. Further details regarding the beacon device will be given below, including potential embodiments thereof. Thus, the at least one beacon device may be or may comprise at least one active beacon device, comprising one or more illumination sources such as one or more light sources like lasers, LEDs, light bulbs or the like. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Alternatively, as outlined above, the infrared spectral range may be used, such as in the range of 780 nm to 3.0 μm . Specifically, the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm may be used. The light emitted by the one or more beacon devices may be non-modulated or may be modulated, as outlined above, in order to distinguish two or more light beams. Additionally or alternatively, the at least one beacon device may be adapted to reflect one or more light beams towards the detector, such as by comprising one or more reflective elements. Further, the at least one beacon device may be or may comprise one or more scattering elements adapted for scattering a light beam. Therein, elastic or inelastic scattering may be used. In case the at least one beacon device is adapted to reflect and/or scatter a primary light beam towards the detector, the beacon device may be adapted to leave the spectral properties of the light beam unaffected or, alternatively, may be adapted to change the spectral properties of the light beam, such as by modifying a wavelength of the light beam.

In a further aspect of the present invention, a human-machine interface for exchanging at least one item of information between a user and a machine is disclosed. The human-machine interface comprises at least one detector system according to the embodiments disclosed above and/or according to one or more of the embodiments disclosed in further detail below. Therein,
5 the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user or held by the user. The human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to assign to the position at least one item of information.

10 In a further aspect of the present invention, an entertainment device for carrying out at least one entertainment function is disclosed. The entertainment device comprises at least one human-machine interface according to the embodiment disclosed above and/or according to one or more of the embodiments disclosed in further detail below. The entertainment device is configured to enable at least one item of information to be input by a player by means of the human-machine interface. The entertainment device is further configured to vary the entertainment
15 function in accordance with the information.

In a further aspect of the present invention, a tracking system for tracking a position of at least one movable object is disclosed. The tracking system comprises at least one detector system
20 according to one or more of the embodiments referring to a detector system as disclosed above and/or as disclosed in further detail below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time.

25 In a further aspect of the present invention, a camera for imaging at least one object is disclosed. The camera comprises at least one detector according to any one of the embodiments referring to a detector as disclosed above or as disclosed in further detail below.

30 In a further aspect of the present invention, a scanning system for determining a depth profile of a scenery, which may also imply determining at least one position of at least one object, is provided. The scanning system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The scanning system further
35 comprises at least one illumination source adapted to scan the scenery with at least one light beam, which may also be referred to as an illumination light beam or scanning light beam. As used herein, the term "scenery" generally refers to a two-dimensional or three-dimensional range which is visible by the detector, such that at least one geometric or spatial property of the two-dimensional or three-dimensional range may be evaluated with the detector. As further
40 used herein, the term "scan" generally refers to a consecutive measurement in different regions. Thus, the scanning specifically may imply at least one first measurement with the illumination light beam being oriented or directed in a first fashion, and at least one second measurement with the illumination light beam being oriented or directed in a second fashion which is different

from the first fashion. The scanning may be a continuous scanning or a stepwise scanning. Thus, in a continuous or stepwise fashion, the illumination light beam may be directed into different regions of the scenery, and the detector may be detected to generate at least one item of information, such as at least one longitudinal coordinate, for each region. As an example, for
5 scanning an object, one or more illumination light beams may, continuously or in a stepwise fashion, create light spots on the surface of the object, wherein longitudinal coordinates are generated for the light spots. Alternatively, however, a light pattern may be used for scanning. The scanning may be a point scanning or a line scanning or even a scanning with more complex light patterns. The illumination source of the scanning system may be distinct from the optional illumination source of the detector. Alternatively, however, the illumination source of the
10 scanning system may also be fully or partially identical with or integrated into the at least one optional illumination source of the detector.

Thus, the scanning system may comprise at least one illumination source which is adapted to
15 emit the at least one light beam being configured for the illumination of the at least one dot located at the at least one surface of the at least one object. As used herein, the term "dot" refers to an area, specifically a small area, on a part of the surface of the object which may be selected, for example by a user of the scanning system, to be illuminated by the illumination source. Preferably, the dot may exhibit a size which may, on one hand, be as small as possible in order
20 to allow the scanning system to determine a value for the distance between the illumination source comprised by the scanning system and the part of the surface of the object on which the dot may be located as exactly as possible and which, on the other hand, may be as large as possible in order to allow the user of the scanning system or the scanning system itself, in particular by an automatic procedure, to detect a presence of the dot on the related part of the surface of the object.
25

For this purpose, the illumination source may comprise an artificial illumination source, in particular at least one laser source and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic
30 and/or inorganic light-emitting diode. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Additionally or alternatively, light in the infrared spectral range may be used, such as in the range of 780 nm to 3.0 μm . Specifically, the light in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm may be used. On account of their generally defined beam profiles and other
35 properties of handleability, the use of at least one laser source as the illumination source is particularly preferred. Herein, the use of a single laser source may be preferred, in particular in a case in which it may be important to provide a compact scanning system that might be easily storable and transportable by the user. The illumination source may, thus, preferably be a constituent part of the detector and may, therefore, in particular be integrated into the detector,
40 such as into the housing of the detector. In a preferred embodiment, particularly the housing of the scanning system may comprise at least one display configured for providing distance-related information to the user, such as in an easy-to-read manner. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least

one button which may be configured for operating at least one function related to the scanning system, such as for setting one or more operation modes. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least one fastening unit which may be configured for fastening the scanning system to a further surface, such as a rubber foot, a base plate or a wall holder, such as a base plate or holder comprising a magnetic material, in particular for increasing the accuracy of the distance measurement and/or the handleability of the scanning system by the user.

Particularly, the illumination source of the scanning system may, thus, emit a single laser beam which may be configured for the illumination of a single dot located at the surface of the object. By using at least one of the detectors according to the present invention at least one item of information about the distance between the at least one dot and the scanning system may, thus, be generated. Hereby, preferably, the distance between the illumination system as comprised by the scanning system and the single dot as generated by the illumination source may be determined, such as by employing the evaluation device as comprised by the at least one detector. However, the scanning system may, further, comprise an additional evaluation system which may, particularly, be adapted for this purpose. Alternatively or in addition, a size of the scanning system, in particular of the housing of the scanning system, may be taken into account and, thus, the distance between a specific point on the housing of the scanning system, such as a front edge or a back edge of the housing, and the single dot may, alternatively, be determined. The illumination source may be adapted to generate and/or to project a cloud of points, for example the illumination source may comprise one or more of at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources.

Alternatively, the illumination source of the scanning system may emit two individual laser beams which may be configured for providing a respective angle, such as a right angle, between the directions of an emission of the beams, whereby two respective dots located at the surface of the same object or at two different surfaces at two separate objects may be illuminated. However, other values for the respective angle between the two individual laser beams may also be feasible. This feature may, in particular, be employed for indirect measuring functions, such as for deriving an indirect distance which may not be directly accessible, such as due to a presence of one or more obstacles between the scanning system and the dot or which may otherwise be hard to reach. By way of example, it may, thus, be feasible to determine a value for a height of an object by measuring two individual distances and deriving the height by using the Pythagoras formula. In particular for being able to keep a predefined level with respect to the object, the scanning system may, further, comprise at least one leveling unit, in particular an integrated bubble vial, which may be used for keeping the predefined level by the user.

As a further alternative, the illumination source of the scanning system may emit a plurality of individual laser beams, such as an array of laser beams which may exhibit a respective pitch, in particular a regular pitch, with respect to each other and which may be arranged in a manner in

order to generate an array of dots located on the at least one surface of the at least one object. For this purpose, specially adapted optical elements, such as beam-splitting devices and mirrors, may be provided which may allow a generation of the described array of the laser beams. In particular, the illumination source may be directed to scan an area or a volume by using one or more movable mirrors to redirect the light beam in a periodic or non-periodic fashion.

Thus, the scanning system may provide a static arrangement of the one or more dots placed on the one or more surfaces of the one or more objects. Alternatively, the illumination source of the scanning system, in particular the one or more laser beams, such as the above described array of the laser beams, may be configured for providing one or more light beams which may exhibit a varying intensity over time and/or which may be subject to an alternating direction of emission in a passage of time, in particular by moving one or more mirrors, such as the micro-mirrors comprised within the mentioned array of micro-mirrors. As a result, the illumination source may be configured for scanning a part of the at least one surface of the at least one object as an image by using one or more light beams with alternating features as generated by the at least one illumination source of the scanning system. In particular, the scanning system may, thus, use at least one row scan and/or line scan, such as to scan the one or more surfaces of the one or more objects sequentially or simultaneously. Thus, the scanning system may be adapted to measure angles by measuring three or more dots, or the scanning system may be adapted to measure corners or narrow regions such as a gable of a roof, which may be hardly accessible using a conventional measuring stick. As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step. As non-limiting examples, the scanning system may be used in industrial safety curtain applications. As non-limiting examples, the scanning system may be used to perform sweeping, vacuuming, mopping, or waxing functions, or yard or garden care functions such as mowing or raking. As non-limiting examples, the scanning system may employ an LED illumination source with collimated optics and may be adapted to shift the frequency of the illumination source to a different frequency to obtain more accurate results and/or employ a filter to attenuate certain frequencies while transmitting others. As non-limiting examples, the scanning system and/or the illumination source may be rotated as a whole or rotating only a particular optics package such as a mirror, beam splitter or the like, using a dedicated motor as such that in operation, the scanning system may have a full 360 degree view or even be moved and or rotated out of plane to further increase the scanned area. Further, the illumination source may be actively aimed in a predetermined direction. Further, to allow the rotation of wired electrical systems, slip rings, optical data transmission, or inductive couplings may be employed.

As a non-limiting example, the scanning system may be attached to a tripod and point towards an object or region with several corners and surfaces. One or more flexibly movable laser sources are attached to the scanning system. The one or more laser sources are moved as

such that they illuminate points of interest. The position of the illuminated points with respect to the scanning system is measured when pressing a designated button on the scanning system and the position information is transmitted via a wireless interface to a mobile phone. The position information is stored in a mobile phone application. The laser sources are moved to illuminate further points of interest the position of which are measured and transmitted to the mobile phone application. The mobile phone application may transform the set of points into a 3d model by connecting adjacent points with planar surfaces. The 3d model may be stored and processed further. The distances and or angles between the measured points or surfaces may be displayed directly on a display attached to a scanning system or on the mobile phone to which the position information is transmitted.

As a non-limiting example, a scanning system may comprise two or more flexible movable laser sources to project points and further one movable laser source projecting a line. The line may be used to arrange the two or more laser spots along a line and the display of the scanning system may display the distance between the two or more laser spots that may be arranged along the line, such as at equal distance. In the case of two laser spots, a single laser source may be used whereas the distance of the projected points is modified using one or more beam-splitters or prisms, where a beam-splitter or prism can be moved as such that the projected laser spots move apart or closer together. Further, the scanning system may be adapted to project further patterns such as a right angle, a circle, a square, a triangle, or the like, along which a measurement can be done by projecting laser spots and measuring their position.

As a non-limiting example, the scanning system may be adapted as a line scanning device. In particular, the scanning system may comprise at least one sensor line or row. Triangulation systems require a sufficient baseline such that in the near field no detection may be possible. Near field detection may be possible if the laser spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. These near field and far field problems can be overcome by using the detector according to the present invention. In particular, the detector may comprise a CMOS line of optical sensors. The scanning system may be adapted to detect a plurality of light beams propagating from the object to the detector on the CMOS line. The light beams may be generated at different positions on the object or by movement of the illumination source. The scanning system may be adapted to determine at least one longitudinal coordinate for each of the light points by determining the quotient signal Q as described above and in more detail below.

As a non-limiting example, the scanning system may be adapted to support the work with tools, such as wood or metal processing tools, such as a saw, a drill, or the like. Thus, the scanning system may be adapted to measure the distance in two opposite directions and display the two measured distances or the sum of the distances in a display. Further, the scanning system may be adapted to measure the distance to the edge of a surface as such that when the scanning system is placed on the surface, a laser point is moved automatically away from the scanning system along the surface, until the distance measurement shows a sudden change due to a corner or the edge of a surface. This makes it possible to measure the distance of the end of a

wood plank while the scanning system is placed on the plank but remote from its end. Further, the scanning system may measure the distance of the end of a plank in one direction and project a line or circle or point in a designated distance in the opposite direction. The scanning system may be adapted to project the line or circle or point in a distance depending on the distance measured in the opposite direction such as depending on a predetermined sum distance. This allows working with a tool such as a saw or driller at the projected position while placing the scanning system in a safe distance from the tool and simultaneously perform a process using the tool in a predetermined distance to the edge of the plank. Further, the scanning system may be adapted to project points or lines or the like in two opposite directions in a predetermined distance. When the sum of the distances is changed, only one of the projected distances changes.

As a non-limiting example, the scanning system may be adapted to be placed onto a surface, such as a surface on which a task is performed, such as cutting, sawing, drilling, or the like, and to project a line onto the surface in a predetermined distance that can be adjusted such as with buttons on the scanning system.

As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step.

The transfer device can, as explained above, be designed to feed light propagating from the object to the detector to the optical sensor, preferably successively. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the optical sensor. The transfer device can also be wholly or partly a constituent part of at least one optional illumination source, for example by the illumination source being designed to provide a light beam having defined optical properties, for example having a defined or precisely known beam profile, for example at least one linear combination of Gaussian beams, in particular at least one laser beam having a known beam profile.

For potential embodiments of the optional illumination source, reference may be made to WO 2012/110924 A1. Still, other embodiments are feasible. Light emerging from the object can originate in the object itself, but can also optionally have a different origin and propagate from this origin to the object and subsequently toward the transversal and/or longitudinal optical sensor. The latter case can be effected for example by at least one illumination source being used. This illumination source can for example be or comprise an ambient illumination source and/or may be or may comprise an artificial illumination source. By way of example, the detector itself can comprise at least one illumination source, for example at least one laser and/or at least one in-

candescent lamp and/or at least one semiconductor illumination source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. On account of their generally defined beam profiles and other properties of handleability, the use of one or a plurality of lasers as illumination source or as part thereof, is particularly preferred. The illumination source itself can be a constituent part of the detector or else be formed independently of the detector. The illumination source can be integrated in particular into the detector, for example a housing of the detector. Alternatively or additionally, at least one illumination source can also be integrated into the at least one beacon device or into one or more of the beacon devices and/or into the object or connected or spatially coupled to the object.

The light emerging from the one or more optional beacon devices can accordingly, alternatively or additionally from the option that said light originates in the respective beacon device itself, emerge from the illumination source and/or be excited by the illumination source. By way of example, the electromagnetic light emerging from the beacon device can be emitted by the beacon device itself and/or be reflected by the beacon device and/or be scattered by the beacon device before it is fed to the detector. In this case, emission and/or scattering of the electromagnetic radiation can be effected without spectral influencing of the electromagnetic radiation or with such influencing. Thus, by way of example, a wavelength shift can also occur during scattering, for example according to Stokes or Raman. Furthermore, emission of light can be excited, for example, by a primary illumination source, for example by the object or a partial region of the object being excited to generate luminescence, in particular phosphorescence and/or fluorescence. Other emission processes are also possible, in principle. If a reflection occurs, then the object can have for example at least one reflective region, in particular at least one reflective surface. Said reflective surface can be a part of the object itself, but can also be for example a reflector which is connected or spatially coupled to the object, for example a reflector plaque connected to the object. If at least one reflector is used, then it can in turn also be regarded as part of the detector which is connected to the object, for example, independently of other constituent parts of the detector.

The beacon devices and/or the at least one optional illumination source generally may emit light in at least one of: the ultraviolet spectral range, preferably in the range of 200 nm to 380 nm; the visible spectral range (380 nm to 780 nm); the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers, more preferably in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm. For thermal imaging applications the target may emit light in the far infrared spectral range, preferably in the range of 3.0 micrometers to 20 micrometers. For example, the at least one illumination source is adapted to emit light in the visible spectral range, preferably in the range of 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm. For example, the at least one illumination source is adapted to emit light in the infrared spectral range. Other options, however, are feasible.

The feeding of the light beam to the optical sensor can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is pro-

duced on the optional sensor area of the optical sensor. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects can be detected. Preferably, the transfer device may be designed in such a way that the light spot, for example in the case of an object arranged within a visual range of the detector, is arranged completely on a sensor region and/or on a sensor area of the optical sensor. By way of example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

In a further aspect, the present invention discloses a method for determining a position of at least one object by using a detector, such as a detector according to the present invention, such as according to one or more of the embodiments referring to a detector as disclosed above or as disclosed in further detail below. Still, other types of detectors may be used. The method comprises the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed. Further, one, more than one or even all of the method steps may be performed repeatedly.

The method comprises the following method steps:

- generating at least two sensor signals in response to an illumination of at least one sensor element having a matrix of optical sensors by at least one reflection light beam propagating from the object to the detector, the optical sensors each having a light-sensitive area;
- determining at least one reflection image by using the sensor element;
- selecting at least one reflection feature of the reflection image and evaluating the sensor signals by using at least one evaluation device, thereby, determining at least one longitudinal region of the selected reflection feature, wherein the evaluating comprises evaluating a combined signal Q from the sensor signals;
- determining at least one displacement region in at least one reference image corresponding to the longitudinal region;
- matching the selected reflection feature with at least one reference feature within the displacement region.

For details, options and definitions, reference may be made to the detector as discussed above. Thus, specifically, as outlined above, the method may comprise using the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below.

The method may further comprise determining a displacement of the matched reference feature and the selected reflection feature. A longitudinal information of the matched feature may be determined using a predetermined relationship between a longitudinal coordinate and the displacement.

The deriving of the combined signal Q may comprise one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

5 In a further aspect of the present invention, use of the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below, is proposed, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a tracking application; a photography application; an imaging application or camera application; a mapping application for generating maps of at least one space; a homing or tracking beacon detector for vehicles; an outdoor application; a mobile application; a communication application; a machine vision application; a robotics application; a quality control application; a manufacturing application.

15 The object generally may be a living or non-living object. The detector or the detector system even may comprise the at least one object, the object thereby forming part of the detector system. Preferably, however, the object may move independently from the detector, in at least one spatial dimension. The object generally may be an arbitrary object. In one embodiment, the object may be a rigid object. Other embodiments are feasible, such as embodiments in which the object is a non-rigid object or an object which may change its shape.

25 As will be outlined in further detail below, the present invention may specifically be used for tracking positions and/or motions of a person, such as for the purpose of controlling machines, gaming or simulation of sports. In this or other embodiments, specifically, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat; an article of clothing; a hat; a shoe.

Thus, generally, the devices according to the present invention, such as the detector, may be applied in various fields of uses. Specifically, the detector may be applied for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a human-machine interface application; a tracking application; a photography application; a mapping application for generating maps of at least one space, such as at least one space selected from the group of a room, a building and a street; a mobile application; a webcam; an audio device; a dolby surround audio system; a computer peripheral device; a gaming application; a camera or video application; a security application; a surveillance application; an automotive application; a transport application; a medical application; a sports' application; a machine vision application; a vehicle application; an airplane application; a ship application; a spacecraft application; a building application; a construction application; a cartography application; a manufacturing application. Additionally or alternatively, applications in local and/or global positioning systems may be named, especially landmark-based positioning and/or navigation, specifically for use in cars or other vehicles (such as trains, motorcycles, bicycles, trucks for cargo transportation), robots or for use by pedestrians. Further, indoor positioning systems may be named as potential applications, such as for house-

hold applications and/or for robots used in manufacturing, logistics, surveillance, or maintenance technology.

5 The devices according to the present invention may be used in mobile phones, tablet computers, laptops, smart panels or other stationary or mobile or wearable computer or communication applications. Thus, the devices according to the present invention may be combined with at least one active light source, such as a light source emitting light in the visible range or infrared spectral range, in order to enhance performance. Thus, as an example, the devices according to the present invention may be used as cameras and/or sensors, such as in combination with
10 mobile software for scanning and/or detecting environment, objects and living beings. The devices according to the present invention may even be combined with 2D cameras, such as conventional cameras, in order to increase imaging effects. The devices according to the present invention may further be used for surveillance and/or for recording purposes or as input devices to control mobile devices, especially in combination with voice and/or gesture recognition. Thus,
15 specifically, the devices according to the present invention acting as human-machine interfaces, also referred to as input devices, may be used in mobile applications, such as for controlling other electronic devices or components via the mobile device, such as the mobile phone. As an example, the mobile application including at least one device according to the present invention may be used for controlling a television set, a game console, a music player or music device or
20 other entertainment devices.

Further, the devices according to the present invention may be used in webcams or other peripheral devices for computing applications. Thus, as an example, the devices according to the present invention may be used in combination with software for imaging, recording, surveillance,
25 scanning or motion detection. As outlined in the context of the human-machine interface and/or the entertainment device, the devices according to the present invention are particularly useful for giving commands by facial expressions and/or body expressions. The devices according to the present invention can be combined with other input generating devices like e.g. mouse, keyboard, touchpad, microphone etc. Further, the devices according to the present invention may be used in applications for gaming, such as by using a webcam. Further, the devices according to the present invention may be used in virtual training applications and/or video conferences. Further, devices according to the present invention may be used to recognize or track hands, arms, or objects used in a virtual or augmented reality application, especially when wearing head-mounted displays.

35 Further, the devices according to the present invention may be used in mobile audio devices, television devices and gaming devices, as partially explained above. Specifically, the devices according to the present invention may be used as controls or control devices for electronic devices, entertainment devices or the like. Further, the devices according to the present invention
40 may be used for eye detection or eye tracking, such as in 2D- and 3D-display techniques, especially with transparent displays for augmented reality applications and/or for recognizing whether a display is being looked at and/or from which perspective a display is being looked at. Further, devices according to the present invention may be used to explore a room, boundaries,

obstacles, in connection with a virtual or augmented reality application, especially when wearing a head-mounted display.

Further, the devices according to the present invention may be used in or as digital cameras such as DSC cameras and/or in or as reflex cameras such as SLR cameras. For these applications, reference may be made to the use of the devices according to the present invention in mobile applications such as mobile phones, as disclosed above.

Further, the devices according to the present invention may be used for security or surveillance applications. Thus, as an example, at least one device according to the present invention can be combined with one or more digital and/or analogue electronics that will give a signal if an object is within or outside a predetermined area (e.g. for surveillance applications in banks or museums). Specifically, the devices according to the present invention may be used for optical encryption. Detection by using at least one device according to the present invention can be combined with other detection devices to complement wavelengths, such as with IR, x-ray, UV-VIS, radar or ultrasound detectors. The devices according to the present invention may further be combined with an active infrared light source to allow detection in low light surroundings. The devices according to the present invention are generally advantageous as compared to active detector systems, specifically since the devices according to the present invention avoid actively sending signals which may be detected by third parties, as is the case e.g. in radar applications, ultrasound applications, LIDAR or similar active detector devices. Thus, generally, the devices according to the present invention may be used for an unrecognized and undetectable tracking of moving objects. Additionally, the devices according to the present invention generally are less prone to manipulations and irritations as compared to conventional devices.

Further, given the ease and accuracy of 3D detection by using the devices according to the present invention, the devices according to the present invention generally may be used for facial, body and person recognition and identification. Therein, the devices according to the present invention may be combined with other detection means for identification or personalization purposes such as passwords, finger prints, iris detection, voice recognition or other means. Thus, generally, the devices according to the present invention may be used in security devices and other personalized applications.

Further, the devices according to the present invention may be used as 3D barcode readers for product identification.

In addition to the security and surveillance applications mentioned above, the devices according to the present invention generally can be used for surveillance and monitoring of spaces and areas. Thus, the devices according to the present invention may be used for surveying and monitoring spaces and areas and, as an example, for triggering or executing alarms in case prohibited areas are violated. Thus, generally, the devices according to the present invention may be used for surveillance purposes in building surveillance or museums, optionally in combination with other types of sensors, such as in combination with motion or heat sensors, in

combination with image intensifiers or image enhancement devices and/or photomultipliers. Further, the devices according to the present invention may be used in public spaces or crowded spaces to detect potentially hazardous activities such as commitment of crimes such as theft in a parking lot or unattended objects such as unattended baggage in an airport.

5

Further, the devices according to the present invention may advantageously be applied in camera applications such as video and camcorder applications. Thus, the devices according to the present invention may be used for motion capture and 3D-movie recording. Therein, the devices according to the present invention generally provide a large number of advantages over conventional optical devices. Thus, the devices according to the present invention generally require a lower complexity with regard to optical components. Thus, as an example, the number of lenses may be reduced as compared to conventional optical devices, such as by providing the devices according to the present invention having one lens only. Due to the reduced complexity, very compact devices are possible, such as for mobile use. Conventional optical systems having two or more lenses with high quality generally are voluminous, such as due to the general need for voluminous beam-splitters. Further, the devices according to the present invention generally may be used for focus/autofocus devices, such as autofocus cameras. Further, the devices according to the present invention may also be used in optical microscopy, especially in confocal microscopy.

20

Further, the devices according to the present invention generally are applicable in the technical field of automotive technology and transport technology. Thus, as an example, the devices according to the present invention may be used as distance and surveillance sensors, such as for adaptive cruise control, emergency brake assist, lane departure warning, surround view, blind spot detection, traffic sign detection, traffic sign recognition, lane recognition, rear cross traffic alert, light source recognition for adapting the head light intensity and range depending on approaching traffic or vehicles driving ahead, adaptive frontlighting systems, automatic control of high beam head lights, adaptive cut-off lights in front light systems, glare-free high beam front lighting systems, marking animals, obstacles, or the like by headlight illumination, rear cross traffic alert, and other driver assistance systems such as advanced driver assistance systems, or other automotive and traffic applications. Further, devices according to the present invention may be used in driver assistance systems anticipating maneuvers of the driver beforehand for collision avoidance or the like. Further, the devices according to the present invention can also be used for velocity and/or acceleration measurements, such as by analyzing a first and second time-derivative of position information gained by using the detector according to the present invention. This feature generally may be applicable in automotive technology, transportation technology or general traffic technology. Applications in other fields of technology are feasible. A specific application in an indoor positioning system may be the detection of positioning of passengers in transportation, more specifically to electronically control the use of safety systems such as airbags. The use of an airbag may be prevented in case the passenger is located as such, that the use of an airbag will cause a severe injury. Further, in vehicles such as cars, trains, planes or the like, especially in autonomous vehicles, devices according to the present

40

invention may be used to determine whether a driver pays attention to the traffic or is distracted, or asleep, or tired, or incapable of driving such as due to the consumption of alcohol or the like.

5 In these or other applications, generally, the devices according to the present invention may be used as standalone devices or in combination with other sensor devices, such as in combination with radar and/or ultrasonic devices. Specifically, the devices according to the present invention may be used for autonomous driving and safety issues. Further, in these applications, the devices according to the present invention may be used in combination with infrared sensors, radar sensors, which are sonic sensors, two-dimensional cameras or other types of sensors. In these applications, the generally passive nature of the devices according to the present invention is advantageous. Thus, since the devices according to the present invention generally do not require emitting signals, the risk of interference of active sensor signals with other signal sources may be avoided. The devices according to the present invention specifically may be used in combination with recognition software, such as standard image recognition software. 10 Thus, signals and data as provided by the devices according to the present invention typically are readily processable and, therefore, generally require lower calculation power than established 3D measurement systems. Given the low space demand, the devices according to the present invention such as cameras may be placed at virtually any place in a vehicle, such as on or behind a window screen, on a front hood, on bumpers, on lights, on mirrors or other places and the like. Various detectors according to the present invention such as one or more detectors based on the effect disclosed within the present invention can be combined, such as in order to allow autonomously driving vehicles or in order to increase the performance of active safety concepts. Thus, various devices according to the present invention may be combined with one or more other devices according to the present invention and/or conventional sensors, 20 such as in the windows like rear window, side window or front window, on the bumpers or on the lights. 25

A combination of at least one device according to the present invention such as at least one detector according to the present invention with one or more rain detection sensors is also possible. This is due to the fact that the devices according to the present invention generally are advantageous over conventional sensor techniques such as radar, specifically during heavy rain. A combination of at least one device according to the present invention with at least one conventional sensing technique such as radar may allow for a software to pick the right combination of signals according to the weather conditions. 30

35 Further, the devices according to the present invention generally may be used as break assist and/or parking assist and/or for speed measurements. Speed measurements can be integrated in the vehicle or may be used outside the vehicle, such as in order to measure the speed of other cars in traffic control. Further, the devices according to the present invention may be used for detecting free parking spaces in parking lots. 40

Further, the devices according to the present invention may be used in the fields of medical systems and sports. Thus, in the field of medical technology, surgery robotics, e.g. for use in endo-

scopes, may be named, since, as outlined above, the devices according to the present invention may require a low volume only and may be integrated into other devices. Specifically, the devices according to the present invention having one lens, at most, may be used for capturing 3D information in medical devices such as in endoscopes. Further, the devices according to the present invention may be combined with an appropriate monitoring software, in order to enable tracking and analysis of movements. This may allow an instant overlay of the position of a medical device, such as an endoscope or a scalpel, with results from medical imaging, such as obtained from magnetic resonance imaging, x-ray imaging, or ultrasound imaging. These applications are specifically valuable e.g. in medical treatments where precise location information is important such as in brain surgery and long-distance diagnosis and tele-medicine. Further, the devices according to the present invention may be used in 3D-body scanning. Body scanning may be applied in a medical context, such as in dental surgery, plastic surgery, bariatric surgery, or cosmetic plastic surgery, or it may be applied in the context of medical diagnosis such as in the diagnosis of myofascial pain syndrome, cancer, body dysmorphic disorder, or further diseases. Body scanning may further be applied in the field of sports to assess ergonomic use or fit of sports equipment. Further, the devices according to the present invention may be used in wearable robots such as in exoskeletons or prosthesis or the like. Body scanning may further be used in the context of clothing, such as to determine a suitable size and fitting of clothes. This technology may be used in the context of tailor-made clothes or in the context of ordering clothes or shoes from the internet or at a self-service shopping device such as a micro kiosk device or customer concierge device. Body scanning in the context of clothing is especially important for scanning fully dressed customers.

Further, the devices according to the present invention may be used in the context of people counting systems, such as to count the number of people in an elevator, a train, a bus, a car, or a plane, or to count the number of people passing a hallway, a door, an aisle, a retail store, a stadium, an entertainment venue, a museum, a library, a public location, a cinema, a theater, or the like. Further, the 3D-function in the people counting system may be used to obtain or estimate further information about the people that are counted such as height, weight, age, physical fitness, or the like. This information may be used for business intelligence metrics, and/or for further optimizing the locality where people may be counted to make it more attractive or safe. In a retail environment, the devices according to the present invention in the context of people counting may be used to recognize returning customers or cross shoppers, to assess shopping behavior, to assess the percentage of visitors that make purchases, to optimize staff shifts, or to monitor the costs of a shopping mall per visitor. Further, people counting systems may be used for anthropometric surveys. Further, the devices according to the present invention may be used in public transportation systems for automatically charging passengers depending on the length of transport. Further, the devices according to the present invention may be used in playgrounds for children, to recognize injured children or children engaged in dangerous activities, to allow additional interaction with playground toys, to ensure safe use of playground toys or the like.

Further, the devices according to the present invention may be used in construction tools, such as a range meter that determines the distance to an object or to a wall, to assess whether a surface is planar, to align objects or place objects in an ordered manner, or in inspection cameras for use in construction environments or the like.

5

Further, the devices according to the present invention may be applied in the field of sports and exercising, such as for training, remote instructions or competition purposes. Specifically, the devices according to the present invention may be applied in the fields of dancing, aerobic, football, soccer, basketball, baseball, cricket, hockey, track and field, swimming, polo, handball, volleyball, rugby, sumo, judo, fencing, boxing, golf, car racing, laser tag, battlefield simulation etc. The devices according to the present invention can be used to detect the position of a ball, a bat, a sword, motions, etc., both in sports and in games, such as to monitor the game, support the referee or for judgment, specifically automatic judgment, of specific situations in sports, such as for judging whether a point or a goal actually was made.

15

Further, the devices according to the present invention may be used in the field of auto racing or car driver training or car safety training or the like to determine the position of a car or the track of a car, or the deviation from a previous track or an ideal track or the like.

20

The devices according to the present invention may further be used to support a practice of musical instruments, in particular remote lessons, for example lessons of string instruments, such as fiddles, violins, violas, celli, basses, harps, guitars, banjos, or ukuleles, keyboard instruments, such as pianos, organs, keyboards, harpsichords, harmoniums, or accordions, and/or percussion instruments, such as drums, timpani, marimbas, xylophones, vibraphones, bongos, congas, timbales, djembes or tablas.

25

The devices according to the present invention further may be used in rehabilitation and physiotherapy, in order to encourage training and/or in order to survey and correct movements. Therein, the devices according to the present invention may also be applied for distance diagnostics.

30

Further, the devices according to the present invention may be applied in the field of machine vision. Thus, one or more of the devices according to the present invention may be used e.g. as a passive controlling unit for autonomous driving and or working of robots. In combination with moving robots, the devices according to the present invention may allow for autonomous movement and/or autonomous detection of failures in parts. The devices according to the present invention may also be used for manufacturing and safety surveillance, such as in order to avoid accidents including but not limited to collisions between robots, production parts and living beings. In robotics, the safe and direct interaction of humans and robots is often an issue, as robots may severely injure humans when they are not recognized. Devices according to the present invention may help robots to position objects and humans better and faster and allow a safe interaction. Given the passive nature of the devices according to the present invention, the devices according to the present invention may be advantageous over active devices and/or may be used complementary to existing solutions like radar, ultrasound, 2D cameras, IR detec-

40

tion etc. One particular advantage of the devices according to the present invention is the low likelihood of signal interference. Therefore, multiple sensors can work at the same time in the same environment, without the risk of signal interference. Thus, the devices according to the present invention generally may be useful in highly automated production environments like e.g. but not limited to automotive, mining, steel, etc. The devices according to the present invention can also be used for quality control in production, e.g. in combination with other sensors like 2-D imaging, radar, ultrasound, IR etc., such as for quality control or other purposes. Further, the devices according to the present invention may be used for assessment of surface quality, such as for surveying the surface evenness of a product or the adherence to specified dimensions, from the range of micrometers to the range of meters. Other quality control applications are feasible. In a manufacturing environment, the devices according to the present invention are especially useful for processing natural products such as food or wood, with a complex 3-dimensional structure to avoid large amounts of waste material. Further, devices according to the present invention may be used to monitor the filling level of tanks, silos etc. Further, devices according to the present invention may be used to inspect complex products for missing parts, incomplete parts, loose parts, low quality parts, or the like, such as in automatic optical inspection, such as of printed circuit boards, inspection of assemblies or sub-assemblies, verification of engineered components, engine part inspections, wood quality inspection, label inspections, inspection of medical devices, inspection of product orientations, packaging inspections, food pack inspections, or the like.

Further, the devices according to the present invention may be used in vehicles, trains, airplanes, ships, spacecraft and other traffic applications. Thus, besides the applications mentioned above in the context of traffic applications, passive tracking systems for aircraft, vehicles and the like may be named. The use of at least one device according to the present invention, such as at least one detector according to the present invention, for monitoring the speed and/or the direction of moving objects is feasible. Specifically, the tracking of fast moving objects on land, sea and in the air including space may be named. The at least one device according to the present invention, such as the at least one detector according to the present invention, specifically may be mounted on a still-standing and/or on a moving device. An output signal of the at least one device according to the present invention can be combined e.g. with a guiding mechanism for autonomous or guided movement of another object. Thus, applications for avoiding collisions or for enabling collisions between the tracked and the steered object are feasible. The devices according to the present invention generally are useful and advantageous due to the low calculation power required, the instant response and due to the passive nature of the detection system which generally is more difficult to detect and to disturb as compared to active systems, like e.g. radar. The devices according to the present invention are particularly useful but not limited to e.g. speed control and air traffic control devices. Further, the devices according to the present invention may be used in automated tolling systems for road charges.

The devices according to the present invention generally may be used in passive applications. Passive applications include guidance for ships in harbors or in dangerous areas, and for aircraft when landing or starting. Therein, fixed, known active targets may be used for precise

guidance. The same can be used for vehicles driving on dangerous but well defined routes, such as mining vehicles. Further, the devices according to the present invention may be used to detect rapidly approaching objects, such as cars, trains, flying objects, animals, or the like. Further, the devices according to the present invention can be used for detecting velocities or accelerations of objects, or to predict the movement of an object by tracking one or more of its position, speed, and/or acceleration depending on time.

Further, as outlined above, the devices according to the present invention may be used in the field of gaming. Thus, the devices according to the present invention can be passive for use with multiple objects of the same or of different size, color, shape, etc., such as for movement detection in combination with software that incorporates the movement into its content. In particular, applications are feasible in implementing movements into graphical output. Further, applications of the devices according to the present invention for giving commands are feasible, such as by using one or more of the devices according to the present invention for gesture or facial recognition. The devices according to the present invention may be combined with an active system in order to work under e.g. low light conditions or in other situations in which enhancement of the surrounding conditions is required. Additionally or alternatively, a combination of one or more devices according to the present invention with one or more IR or VIS light sources is possible. A combination of a detector according to the present invention with special devices is also possible, which can be distinguished easily by the system and its software, e.g. and not limited to, a special color, shape, relative position to other devices, speed of movement, light, frequency used to modulate light sources on the device, surface properties, material used, reflection properties, transparency degree, absorption characteristics, etc. The device can, amongst other possibilities, resemble a stick, a racket, a club, a gun, a knife, a wheel, a ring, a steering wheel, a bottle, a ball, a glass, a vase, a spoon, a fork, a cube, a dice, a figure, a puppet, a teddy, a beaker, a pedal, a switch, a glove, jewelry, a musical instrument or an auxiliary device for playing a musical instrument, such as a plectrum, a drumstick or the like. Other options are feasible.

Further, the devices according to the present invention may be used to detect and/or track objects that emit light by themselves, such as due to high temperature or further light emission processes. The light emitting part may be an exhaust stream or the like. Further, the devices according to the present invention may be used to track reflecting objects and analyze the rotation or orientation of these objects.

Further, the devices according to the present invention generally may be used in the field of building, construction and cartography. Thus, generally, one or more devices according to the present invention may be used in order to measure and/or monitor environmental areas, e.g. countryside or buildings. Therein, one or more devices according to the present invention may be combined with other methods and devices or can be used solely in order to monitor progress and accuracy of building projects, changing objects, houses, etc. The devices according to the present invention can be used for generating three-dimensional models of scanned environments, in order to construct maps of rooms, streets, houses, communities or landscapes, both

from ground or from air. Potential fields of application may be construction, cartography, real estate management, land surveying or the like. As an example, the devices according to the present invention may be used in drones or multicopters to monitor buildings, production sites, chimneys, agricultural production environments such as fields, production plants, or landscapes, to support rescue operations, to support work in dangerous environments, to support fire brigades in a burning location indoors or outdoors, or to find or monitor one or more persons or animals, or the like, or for entertainment purposes, such as a drone following and recording one or more persons doing sports such as skiing or cycling or the like, which could be realized by following a helmet, a mark, a beacon device, or the like. Devices according to the present invention could be used recognize obstacles, follow a predefined route, follow an edge, a pipe, a building, or the like, or to record a global or local map of the environment. Further, devices according to the present invention could be used for indoor or outdoor localization and positioning of drones, for stabilizing the height of a drone indoors where barometric pressure sensors are not accurate enough, or for the interaction of multiple drones such as concertized movements of several drones or recharging or refueling in the air or the like.

Further, the devices according to the present invention may be used within an interconnecting network of home appliances such as CHAIN (Cedec Home Appliances Interoperating Network) to interconnect, automate, and control basic appliance-related services in a home, e.g. energy or load management, remote diagnostics, pet related appliances, child related appliances, child surveillance, appliances related surveillance, support or service to elderly or ill persons, home security and/or surveillance, remote control of appliance operation, and automatic maintenance support. Further, the devices according to the present invention may be used in heating or cooling systems such as an air-conditioning system, to locate which part of the room should be brought to a certain temperature or humidity, especially depending on the location of one or more persons. Further, the devices according to the present invention may be used in domestic robots, such as service or autonomous robots which may be used for household chores. The devices according to the present invention may be used for a number of different purposes, such as to avoid collisions or to map the environment, but also to identify a user, to personalize the robot's performance for a given user, for security purposes, or for gesture or facial recognition. As an example, the devices according to the present invention may be used in robotic vacuum cleaners, floor-washing robots, dry-sweeping robots, ironing robots for ironing clothes, animal litter robots, such as dog or cat litter robots, charging robot for electrical vehicles, security robots that detect intruders, robotic lawn mowers, automated pool cleaners, rain gutter cleaning robots, robotic shopping carts, luggage carrying robots, line following robots, laundry robots, ironing robots, window washing robots, toy robots, patient monitoring robots, baby monitoring robots, elderly monitoring robots, children monitoring robots, transport robots, telepresence robots, professional service robots, programmable toy robots, pathfinder robots, social robots providing company to less mobile people, following robots, smart card following robots, psychotherapy robots, or robots translating speech to sign language or sign language to speech. In the context of less mobile people, such as elderly persons, household robots with the devices according to the present invention may be used for picking up objects, transporting objects, and interacting with the objects and the user in a safe way. Further, the devices according to the

present invention may be used in humanoid robots, especially in the context of using humanoid hands to pick up or hold or place objects. Further, the devices according to the present invention may be used in combination with audio interfaces especially in combination with household robots which may serve as a digital assistant with interfaces to online or offline computer applications. Further, the devices according to the present invention may be used in robots that can control switches and buttons in industrial and household purposes. Further, the devices according to the present invention may be used in smart home robots such as Mayfield's Kuri. Further the devices according to the present invention may be used in robots operating with hazardous materials or objects or in dangerous environments. As a non-limiting example, the devices according to the present invention may be used in robots or unmanned remote-controlled vehicles to operate with hazardous materials such as chemicals or radioactive materials especially after disasters, or with other hazardous or potentially hazardous objects such as mines, unexploded arms, or the like, or to operate in or to investigate insecure environments such as near burning objects or post disaster areas or for manned or unmanned rescue operations in the air, in the sea, underground, or the like.

Further, devices according to the present invention may be used for the inspection of adhesive beads, sealing beads, or the like, such as to recognize disruptions, slubs, contractions, asymmetries, local defects, or the like. Further, devices according to the present invention may be used to count objects such as dry fruits on a conveyer belt, such as in difficult situations, such as when fruit of similar color and shape may be in direct contact with each other. Further, devices according to the present invention may be used in quality control of die cast or injection molded parts such as to ensure flawless casting or molding, recognize surface damages, worn out toolings or the like. Further, devices according to the present invention may be used for laserscribing such as for quality control and positioning of the laser. Further, devices according to the present invention may be used for sorting systems, such as to detect position, rotation, and shape of an object, compare it to a database of objects, and classify the object. Further, devices according to the present invention may be used for stamping part inspection, packaging inspection, such as food and pharma packaging inspection, filament inspection, or the like.

Further, devices according to the present invention may be used for navigation purposes, where Global Positioning Systems (GPS) are not sufficiently reliable. GPS signals commonly use radio waves that are can be blocked or difficult to receive indoors or outdoors in valleys or in forests below the treeline. Further, especially in unmanned autonomous vehicles, the weight of the system may be critical. Especially unmanned autonomous vehicles need high-speed position data for reliable feedback and stability of their control systems. Using devices according to the present invention may allow short time response and positioning without adding weight due to a heavy device.

Further, the devices according to the present invention may be used in household, mobile or entertainment devices, such as a refrigerator, a microwave, a washing machine, a window blind or shutter, a household alarm, an air condition devices, a heating device, a television, an audio device, a smart watch, a mobile phone, a phone, a dishwasher, a stove or the like, to detect the

presence of a person, to monitor the contents or function of the device, or to interact with the person and/or share information about the person with further household, mobile or entertainment devices.

- 5 Further, the devices according to the present invention may be used to support elderly or disabled persons or persons with limited or no vision, such as in household chores or at work such as in devices for holding, carrying, or picking objects, or in a safety system with optical or acoustical signals signaling obstacles in the environment.
- 10 The devices according to the present invention may further be used in agriculture, for example to detect and sort out vermin, weeds, and/or infected crop plants, fully or in parts, wherein crop plants may be infected by fungus or insects. Further, for harvesting crops, the devices according to the present invention may be used to detect animals, such as deer, which may otherwise be harmed by harvesting devices. Further, the devices according to the present invention may
- 15 be used to monitor the growth of plants in a field or greenhouse, in particular to adjust the amount of water or fertilizer or crop protection products for a given region in the field or greenhouse or even for a given plant. Further, in agricultural biotechnology, the devices according to the present invention may be used to monitor the size and shape of plants.
- 20 Further, devices according to the present invention may be used to automatically remove weeds such as with mechanical means, such as to avoid the use of herbicides. Further, devices according to the present invention may be used in the field of agriculture, in particular to detect and/or locate specific insects such as to decide whether or not to apply a crop protection or fertilization substance, such as to reduce the amount of applied substance or to protect specific
- 25 groups of animals such as bees.

Further, devices according to the present invention may be used to guide users during a shaving, hair cutting, or cosmetics procedure, or the like. Further, devices according to the present invention may be used to record or monitor what is played on an instrument, such as a violin.

- 30 Further, devices according to the present invention may be used in smart household appliances such as a smart refrigerator, such as to monitor the contents of the refrigerator and transmit notifications depending on the contents. Further, devices according to the present invention may be used for monitoring or tracking populations of humans, animals, or plants, such as deer or tree populations in forests. Further, devices according to the present invention may be used
- 35 in harvesting machines, such as for harvesting crops, flowers or fruits, such as grapes, corn, hops, apples, grains, rice, strawberries, asparagus, tulips, roses, soy beans, or the like. Further, devices according to the present invention may be used to monitor the growth of plants, animals, algae, fish, or the like, such as in breeding, food production, agriculture or research applications, to control irrigation, fertilization, humidity, temperature, use of herbicides, insecticides, fungicides, rodenticides, or the like. Further, devices according to the present invention may be
- 40 used in feeding machines for animals or pets, such as for cows, pigs, cats, dogs, birds, fish, or the like. Further, devices according to the present invention may be used in animal product production processes, such as for collecting milk, eggs, fur, meat, or the like, such as in automated

milking or butchering processes. Further, devices according to the present invention may be used for automated seeding machines, or sowing machines, or planting machines such as for planting corn, garlic, trees, salad or the like. Further, devices according to the present invention may be used to assess or monitor weather phenomena, such as clouds, fog, or the like, or to warn from danger of avalanches, tsunamis, gales, earthquakes, thunder storms, or the like. Further, devices according to the present invention may be used to measure motions, shocks, concussions, or the like such as to monitor earthquake risk. Further, devices according to the present invention may be used in traffic technology to monitor dangerous crossings, to control traffic lights depending on traffic, to monitor public spaces, to monitor roads, gyms, stadiums, ski resorts, public events, or the like. Further, devices according to the present invention may be used in medical applications such as to monitor or analyze tissues, medical or biological assays, changes in tissues such as in moles or melanoma or the like, to count bacteria, blood cells, cells, algae, or the like, for retina scans, breath or pulse measurements, gastroscopy, patient surveillance, or the like. Further, devices according to the present invention may be used to monitor the shape, size, or circumference of drops, streams, jets, or the like or to analyze, assess, or monitor profiles or gas or liquid currents such as in a wind channel, or the like. Further, devices according to the present invention may be used to warn drivers such as car or train drivers when they are getting sick or tired or the like. Further, devices according to the present invention may be used in material testing to recognize strains or tensions or fissures, or the like. Further, devices according to the present invention may be used in sailing to monitor and optimize sail positions such as automatically. Further, devices according to the present invention may be used for fuel level gauges.

Further, the devices according to the present invention may be combined with sensors to detect chemicals or pollutants, electronic nose chips, microbe sensor chips to detect bacteria or viruses or the like, Geiger counters, tactile sensors, heat sensors, or the like. This may for example be used in constructing smart robots which are configured for handling dangerous or difficult tasks, such as in treating highly infectious patients, handling or removing highly dangerous substances, cleaning highly polluted areas, such as highly radioactive areas or chemical spills, or for pest control in agriculture.

One or more devices according to the present invention can further be used for scanning of objects, such as in combination with CAD or similar software, such as for additive manufacturing and/or 3D printing. Therein, use may be made of the high dimensional accuracy of the devices according to the present invention, e.g. in x-, y- or z- direction or in any arbitrary combination of these directions, such as simultaneously. Further, the devices according to the present invention may be used in inspections and maintenance, such as pipeline inspection gauges. Further, in a production environment, the devices according to the present invention may be used to work with objects of a badly defined shape such as naturally grown objects, such as sorting vegetables or other natural products by shape or size or cutting products such as meat or objects that are manufactured with a precision that is lower than the precision needed for a processing step.

Further, the devices according to the present invention may be used in local navigation systems to allow autonomously or partially autonomously moving vehicles or multicopters or the like through an indoor or outdoor space. A non-limiting example may comprise vehicles moving through an automated storage for picking up objects and placing them at a different location.

- 5 Indoor navigation may further be used in shopping malls, retail stores, museums, airports, or train stations, to track the location of mobile goods, mobile devices, baggage, customers or employees, or to supply users with a location specific information, such as the current position on a map, or information on goods sold, or the like.
- 10 Further, the devices according to the present invention may be used to ensure safe driving of motorcycles such as driving assistance for motorcycles by monitoring speed, inclination, upcoming obstacles, unevenness of the road, or curves or the like. Further, the devices according to the present invention may be used in trains or trams to avoid collisions.
- 15 Further, the devices according to the present invention may be used in handheld devices, such as for scanning packaging or parcels to optimize a logistics process. Further, the devices according to the present invention may be used in further handheld devices such as personal shopping devices, RFID-readers, handheld devices for use in hospitals or health environments such as for medical use or to obtain, exchange or record patient or patient health related information, smart badges for retail or health environments, or the like.
- 20

- As outlined above, the devices according to the present invention may further be used in manufacturing, quality control or identification applications, such as in product identification or size identification (such as for finding an optimal place or package, for reducing waste etc.). Further,
- 25 the devices according to the present invention may be used in logistics applications. Thus, the devices according to the present invention may be used for optimized loading or packing containers or vehicles. Further, devices according to the present invention may be recalibrated using bar codes, QR-codes or prerecorded symbols of known size by using the at least one image matrix and comparing the prerecorded size with a measured property of the recorded image of
- 30 the bar code, QR code or prerecorded symbol, such as by comparing the width or height of the symbol with a prerecorded value. Further, the devices according to the present invention may be used for monitoring or controlling of surface damages in the field of manufacturing, for monitoring or controlling rental objects such as rental vehicles, and/or for insurance applications, such as for assessment of damages. Further, the devices according to the present invention
- 35 may be used for identifying a size of material, object or tools, such as for optimal material handling, especially in combination with robots. Further, the devices according to the present invention may be used for process control in production, e.g. for observing filling level of tanks. Further, the devices according to the present invention may be used for maintenance of production assets like, but not limited to, tanks, pipes, reactors, tools etc. Further, the devices according to
- 40 the present invention may be used for analyzing 3D-quality marks. Further, the devices according to the present invention may be used in manufacturing tailor-made goods such as tooth inlays, dental braces, prosthesis, clothes or the like. The devices according to the present invention may also be combined with one or more 3D-printers for rapid prototyping, 3D-copying or the

like. Further, the devices according to the present invention may be used for detecting the shape of one or more articles, such as for anti-product piracy and for anti-counterfeiting purposes.

5 Thus, specifically, the present application may be applied in the field of photography. Thus, the detector may be part of a photographic device, specifically of a digital camera. Specifically, the detector may be used for 3D photography, specifically for digital 3D photography. Thus, the detector may form a digital 3D camera or may be part of a digital 3D camera. As used herein, the term photography generally refers to the technology of acquiring image information of at least
10 one object. As further used herein, a camera generally is a device adapted for performing photography. As further used herein, the term digital photography generally refers to the technology of acquiring image information of at least one object by using a plurality of light-sensitive elements adapted to generate electrical signals indicating an intensity and/or color of illumination, preferably digital electrical signals. As further used herein, the term 3D photography generally
15 refers to the technology of acquiring image information of at least one object in three spatial dimensions. Accordingly, a 3D camera is a device adapted for performing 3D photography. The camera generally may be adapted for acquiring a single image, such as a single 3D image, or may be adapted for acquiring a plurality of images, such as a sequence of images. Thus, the camera may also be a video camera adapted for video applications, such as for acquiring digital
20 video sequences.

Thus, generally, the present invention further refers to a camera, specifically a digital camera, more specifically a 3D camera or digital 3D camera, for imaging at least one object. As outlined above, the term imaging, as used herein, generally refers to acquiring image information of at
25 least one object. The camera comprises at least one detector according to the present invention. The camera, as outlined above, may be adapted for acquiring a single image or for acquiring a plurality of images, such as image sequence, preferably for acquiring digital video sequences. Thus, as an example, the camera may be or may comprise a video camera. In the latter case, the camera preferably comprises a data memory for storing the image sequence.

30 As used within the present invention, the expression "position" generally refers to at least one item of information regarding one or more of an absolute position and an orientation of one or more points of the object. Thus, specifically, the position may be determined in a coordinate system of the detector, such as in a Cartesian coordinate system. Additionally or alternatively,
35 however, other types of coordinate systems may be used, such as polar coordinate systems and/or spherical coordinate systems.

As outlined above and as will be outlined in further detail below, the present invention preferably may be applied in the field of human-machine interfaces, in the field of sports and/or in the field
40 of computer games. Thus, preferably, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat, an article of clothing, a hat, a shoe. Other embodiments are feasible.

As used herein, the object generally may be an arbitrary object, chosen from a living object and a non-living object. Thus, as an example, the at least one object may comprise one or more articles and/or one or more parts of an article. Additionally or alternatively, the object may be or may comprise one or more living beings and/or one or more parts thereof, such as one or more body parts of a human being, e.g. a user, and/or an animal.

With regard to the coordinate system for determining the position of the object, which may be a coordinate system of the detector, the detector may constitute a coordinate system in which an optical axis of the detector forms the z-axis and in which, additionally, an x-axis and a y-axis may be provided which are perpendicular to the z-axis and which are perpendicular to each other. As an example, the detector and/or a part of the detector may rest at a specific point in this coordinate system, such as at the origin of this coordinate system. In this coordinate system, a direction parallel or antiparallel to the z-axis may be regarded as a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. An arbitrary direction perpendicular to the longitudinal direction may be considered a transversal direction, and an x- and/or y-coordinate may be considered a transversal coordinate.

Alternatively, other types of coordinate systems may be used. Thus, as an example, a polar coordinate system may be used in which the optical axis forms a z-axis and in which a distance from the z-axis and a polar angle may be used as additional coordinates. Again, a direction parallel or antiparallel to the z-axis may be considered a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. Any direction perpendicular to the z-axis may be considered a transversal direction, and the polar coordinate and/or the polar angle may be considered a transversal coordinate.

The detector may be a device configured for providing at least one item of information on the position of the at least one object and/or a part thereof. Thus, the position may refer to an item of information fully describing the position of the object or a part thereof, preferably in the coordinate system of the detector, or may refer to a partial information, which only partially describes the position. The detector generally may be a device adapted for detecting light beams, such as the light beams propagating from the beacon devices towards the detector.

The evaluation device and the detector may fully or partially be integrated into a single device. Thus, generally, the evaluation device also may form part of the detector. Alternatively, the evaluation device and the detector may fully or partially be embodied as separate devices. The detector may comprise further components.

The detector may be a stationary device or a mobile device. Further, the detector may be a stand-alone device or may form part of another device, such as a computer, a vehicle or any other device. Further, the detector may be a hand-held device. Other embodiments of the detector are feasible.

The detector specifically may be used to record a light-field behind a lens or lens system of the detector, comparable to a plenoptic or light-field camera. Thus, specifically, the detector may be embodied as a light-field camera adapted for acquiring images in multiple focal planes, such as simultaneously. The term light-field, as used herein, generally refers to the spatial light propagation of light inside the detector such as inside camera. The detector according to the present invention, specifically having a stack of optical sensors, may have the capability of directly recording a light-field within the detector or camera, such as behind a lens. The plurality of sensors may record images at different distances from the lens. Using, e.g., convolution-based algorithms such as "depth from focus" or "depth from defocus", the propagation direction, focus points, and spread of the light behind the lens can be modeled. From the modeled propagation of light behind the lens, images at various distances to the lens can be extracted, the depth of field can be optimized, pictures that are in focus at various distances can be extracted, or distances of objects can be calculated. Further information may be extracted.

The use of several optical sensors further allows for correcting lens errors in an image processing step after recording the images. Optical instruments often become expensive and challenging in construction, when lens errors need to be corrected. These are especially problematic in microscopes and telescopes. In microscopes, a typical lens error is that rays of varying distance to the optical axis are distorted differently (spherical aberration). In telescopes, varying the focus may occur from differing temperatures in the atmosphere. Static errors such as spherical aberration or further errors from production may be corrected by determining the errors in a calibration step and then using a fixed image processing such as fixed set of pixels and sensor, or more involved processing techniques using light propagation information. In cases in which lens errors are strongly time-dependent, i.e. dependent on weather conditions in telescopes, the lens errors may be corrected by using the light propagation behind the lens, calculating extended depth of field images, using depth from focus techniques, and others.

The detector according to the present invention may further allow for color detection. For color detection, a plurality of optical sensors having different spectral properties may be used, and sensor signals of these optical sensors may be compared. Further, the devices according to the present invention may be used in the context of gesture recognition. In this context, gesture recognition in combination with devices according to the present invention may, in particular, be used as a human-machine interface for transmitting information via motion of a body, of body parts or of objects to a machine. Herein, the information may, preferably, be transmitted via a motion of hands or hand parts, such as fingers, in particular, by pointing at objects, applying sign language, such as for deaf people, making signs for numbers, approval, disapproval, or the like, by waving the hand, such as when asking someone to approach, to leave, or to greet a person, to press an object, to take an object, or, in the field of sports or music, in a hand or finger exercise, such as a warm-up exercise. Further, the information may be transmitted by motion of arms or legs, such as rotating, kicking, grabbing, twisting, rotating, scrolling, browsing, pushing, bending, punching, shaking, arms, legs, both arms, or both legs, or a combination of arms and legs, such as for a purpose of sports or music, such as for entertainment, exercise, or training function of a machine. Further, the information may be transmitted by motion of the

whole body or major parts thereof, such as jumping, rotating, or making complex signs, such as sign language used at airports or by traffic police in order to transmit information, such as “turn right”, “turn left”, “proceed”, “slow down”, “stop”, or “stop engines”, or by pretending to swim, to dive, to run, to shoot, or the like, or by making complex motions or body positions such as in
5 yoga, pilates, judo, karate, dancing, or ballet. Further, the information may be transmitted by using a real or mock-up device for controlling a virtual device corresponding to the mock-up device, such as using a mock-up guitar for controlling a virtual guitar function in a computer program, using a real guitar for controlling a virtual guitar function in a computer program, using
10 a real or a mock-up book for reading an e-book or moving pages or browsing through in a virtual document, using a real or mock-up pen for drawing in a computer program, or the like. Further, the transmission of the information may be coupled to a feedback to the user, such as a sound, a vibration, or a motion.

15 In the context of music and/or instruments, devices according to the present invention in combination with gesture recognition may be used for exercising purposes, control of instruments, recording of instruments, playing or recording of music via use of a mock-up instrument or by only pretending to have a instrument present such as playing air guitar, such as to avoid noise or make recordings, or, for conducting of a virtual orchestra, ensemble, band, big band, choir, or the like, for practicing, exercising, recording or entertainment purposes or the like.

20 Further, in the context of safety and surveillance, devices according to the present invention in combination with gesture recognition may be used to recognize motion profiles of persons, such as recognizing a person by the way of walking or moving the body, or to use hand signs or movements or signs or movements of body parts or the whole body as access or identification
25 control such as a personal identification sign or a personal identification movement.

Further, in the context of smart home applications or internet of things, devices according to the present invention in combination with gesture recognition may be used for central or non-central
30 control of household devices which may be part of an interconnecting network of home appliances and/or household devices, such as refrigerators, central heating, air condition, microwave ovens, ice cube makers, or water boilers, or entertainment devices, such as television sets, smart phones, game consoles, video recorders, DVD players, personal computers, laptops, tablets, or combinations thereof, or a combination of household devices and entertainment devices.

35 Further, in the context of virtual reality or of augmented reality, devices according to the present invention in combination with gesture recognition may be used to control movements or function of the virtual reality application or of the augmented reality application, such as playing or controlling a game using signs, gestures, body movements or body part movements or the like,
40 moving through a virtual world, manipulating virtual objects, practicing, exercising or playing sports, arts, crafts, music or games using virtual objects such as a ball, chess figures, go stones, instruments, tools, brushes.

Further, in the context of medicine, devices according to the present invention in combination with gesture recognition may be used to support rehabilitation training, remote diagnostics, or to monitor or survey surgery or treatment, to overlay and display medical images with positions of medical devices, or to overlay display prerecorded medical images such as from magnetic resonance tomography or x-ray or the like with images from endoscopes or ultra sound or the like that are recorded during a surgery or treatment.

Further, in the context of manufacturing and process automation, devices according to the present invention in combination with gesture recognition may be used to control, teach, or program robots, drones, unmanned autonomous vehicles, service robots, movable objects, or the like, such as for programming, controlling, manufacturing, manipulating, repairing, or teaching purposes, or for remote manipulating of objects or areas, such as for safety reasons, or for maintenance purposes.

Further, in the context of business intelligence metrics, devices according to the present invention in combination with gesture recognition may be used for people counting, surveying customer movements, areas where customers spend time, objects, customers test, take, probe, or the like.

Further, devices according to the present invention may be used in the context of do-it-yourself or professional tools, especially electric or motor driven tools or power tools, such as drilling machines, saws, chisels, hammers, wrenches, staple guns, disc cutters, metals shears and nibblers, angle grinders, die grinders, drills, hammer drills, heat guns, wrenches, sanders, engravers, nailers, jig saws, biscuit joiners, wood routers, planers, polishers, tile cutters, washers, rollers, wall chasers, lathes, impact drivers, jointers, paint rollers, spray guns, morticers, or welders, in particular, to support precision in manufacturing, keeping a minimum or maximum distance, or for safety measures.

Further, the devices according to the present invention may be used to aid visually impaired persons. Further, devices according to the present invention may be used in touch screen such as to avoid direct contact such as for hygienic reasons, which may be used in retail environments, in medical applications, in production environments, or the like. Further, devices according to the present invention may be used in agricultural production environments such as in stable cleaning robots, egg collecting machines, milking machines, harvesting machines, farm machinery, harvesters, forwarders, combine harvesters, tractors, cultivators, ploughs, destoners, harrows, strip tills, broadcast seeders, planters such as potato planters, manure spreaders, sprayers, sprinkler systems, swathers, balers, loaders, forklifts, mowers, or the like.

Further, devices according to the present invention may be used for selection and/or adaption of clothing, shoes, glasses, hats, prosthesis, dental braces, for persons or animals with limited communication skills or possibilities, such as children or impaired persons, or the like. Further, devices according to the present invention may be used in the context of warehouses, logistics, distribution, shipping, loading, unloading, smart manufacturing, industry 4.0, or the like. Further,

in a manufacturing context, devices according to the present invention may be used in the context of processing, dispensing, bending, material handling, or the like.

5 The evaluation device may be or may comprise one or more integrated circuits, such as one or more application-specific integrated circuits (ASICs), and/or one or more data processing devices, such as one or more computers, preferably one or more microcomputers and/or microcontrollers, Field Programmable Arrays, or Digital Signal Processors. Additional components may be comprised, such as one or more preprocessing devices and/or data acquisition devices, such as one or more devices for receiving and/or preprocessing of the sensor signals, such as
10 one or more AD-converters and/or one or more filters. Further, the evaluation device may comprise one or more measurement devices, such as one or more measurement devices for measuring electrical currents and/or electrical voltages. Further, the evaluation device may comprise one or more data storage devices. Further, the evaluation device may comprise one or more interfaces, such as one or more wireless interfaces and/or one or more wire-bound interfaces.

15 The at least one evaluation device may be adapted to perform at least one computer program, such as at least one computer program adapted for performing or supporting one or more or even all of the method steps of the method according to the present invention. As an example, one or more algorithms may be implemented which, by using the sensor signals as input variables, may determine the position of the object.
20

The evaluation device can be connected to or may comprise at least one further data processing device that may be used for one or more of displaying, visualizing, analyzing, distributing, communicating or further processing of information, such as information obtained by the
25 optical sensor and/or by the evaluation device. The data processing device, as an example, may be connected or incorporate at least one of a display, a projector, a monitor, an LCD, a TFT, a loudspeaker, a multichannel sound system, an LED pattern, or a further visualization device. It may further be connected or incorporate at least one of a communication device or communication interface, a connector or a port, capable of sending encrypted or unencrypted
30 information using one or more of email, text messages, telephone, Bluetooth, Wi-Fi, infrared or internet interfaces, ports or connections. It may further be connected to or incorporate at least one of a processor, a graphics processor, a CPU, an Open Multimedia Applications Platform (OMAP™), an integrated circuit, a system on a chip such as products from the Apple A series or the Samsung S3C2 series, a microcontroller or microprocessor, one or more memory blocks
35 such as ROM, RAM, EEPROM, or flash memory, timing sources such as oscillators or phase-locked loops, counter-timers, real-time timers, or power-on reset generators, voltage regulators, power management circuits, or DMA controllers. Individual units may further be connected by buses such as AMBA buses or be integrated in an Internet of Things or Industry 4.0 type network.

40 The evaluation device and/or the data processing device may be connected by or have further external interfaces or ports such as one or more of serial or parallel interfaces or ports, USB, Centronics Port, FireWire, HDMI, Ethernet, Bluetooth, RFID, Wi-Fi, USART, or SPI, or analogue

interfaces or ports such as one or more of ADCs or DACs, or standardized interfaces or ports to further devices such as a 2D-camera device using an RGB-interface such as CameraLink. The evaluation device and/or the data processing device may further be connected by one or more of interprocessor interfaces or ports, FPGA-FPGA-interfaces, or serial or parallel interfaces
5 ports. The evaluation device and the data processing device may further be connected to one or more of an optical disc drive, a CD-RW drive, a DVD+RW drive, a flash drive, a memory card, a disk drive, a hard disk drive, a solid state disk or a solid state hard disk.

The evaluation device and/or the data processing device may be connected by or have one or
10 more further external connectors such as one or more of phone connectors, RCA connectors, VGA connectors, hermaphrodite connectors, USB connectors, HDMI connectors, 8P8C connectors, BCN connectors, IEC 60320 C14 connectors, optical fiber connectors, D-subminiature connectors, RF connectors, coaxial connectors, SCART connectors, XLR connectors, and/or may incorporate at least one suitable socket for one or more of these connectors.

Possible embodiments of a single device incorporating one or more of the detectors according to the present invention, the evaluation device or the data processing device, such as incorporating one or more of the optical sensor, optical systems, evaluation device, communication
15 device, data processing device, interfaces, system on a chip, display devices, or further electronic devices, are: mobile phones, personal computers, tablet PCs, televisions, game consoles or further entertainment devices. In a further embodiment, the 3D-camera functionality which will be outlined in further detail below may be integrated in devices that are available with conventional 2D-digital cameras, without a noticeable difference in the housing or appearance of the device, where the noticeable difference for the user may only be the functionality of obtaining and or processing 3D information. Further, devices according to the present invention may
20 be used in 360° digital cameras or surround view cameras.

Specifically, an embodiment incorporating the detector and/or a part thereof such as the evaluation device and/or the data processing device may be: a mobile phone incorporating a display
30 device, a data processing device, the optical sensor, optionally the sensor optics, and the evaluation device, for the functionality of a 3D camera. The detector according to the present invention specifically may be suitable for integration in entertainment devices and/or communication devices such as a mobile phone.

A further embodiment of the present invention may be an incorporation of the detector or a part thereof such as the evaluation device and/or the data processing device in a device for use in automotive, for use in autonomous driving or for use in car safety systems such as Daimler's Intelligent Drive system, wherein, as an example, a device incorporating one or more of the optical sensors, optionally one or more optical systems, the evaluation device, optionally a communication device, optionally a data processing device, optionally one or more interfaces, optionally a system on a chip, optionally one or more display devices, or optionally further electronic devices may be part of a vehicle, a car, a truck, a train, a bicycle, an airplane, a ship, a motorcycle. In automotive applications, the integration of the device into the automotive design
40

may necessitate the integration of the optical sensor, optionally optics, or device at minimal visibility from the exterior or interior. The detector or a part thereof such as the evaluation device and/or the data processing device may be especially suitable for such integration into automotive design.

5

As used herein, the term light generally refers to electromagnetic radiation in one or more of the visible spectral range, the ultraviolet spectral range and the infrared spectral range. Therein, the term visible spectral range generally refers to a spectral range of 380 nm to 780 nm. The term infrared spectral range generally refers to electromagnetic radiation in the range of 780 nm to 1 mm, preferably in the range of 780 nm to 3.0 micrometers. The term ultraviolet spectral range generally refers to electromagnetic radiation in the range of 1 nm to 380 nm, preferably in the range of 100 nm to 380 nm. Preferably, light as used within the present invention is visible light, i.e. light in the visible spectral range.

10

15

The term light beam generally may refer to an amount of light emitted and/or reflected into a specific direction. Thus, the light beam may be a bundle of the light rays having a predetermined extension in a direction perpendicular to a direction of propagation of the light beam. Preferably, the light beams may be or may comprise one or more Gaussian light beams such as a linear combination of Gaussian light beams, which may be characterized by one or more Gaussian beam parameters, such as one or more of a beam waist, a Rayleigh-length or any other beam parameter or combination of beam parameters suited to characterize a development of a beam diameter and/or a beam propagation in space.

20

25

The detector according to the present invention may further be combined with one or more other types of sensors or detectors. Thus, the detector may further comprise at least one additional detector. The at least one additional detector may be adapted for detecting at least one parameter, such as at least one of: a parameter of a surrounding environment, such as a temperature and/or a brightness of a surrounding environment; a parameter regarding a position and/or orientation of the detector; a parameter specifying a state of the object to be detected, such as a position of the object, e.g. an absolute position of the object and/or an orientation of the object in space. Thus, generally, the principles of the present invention may be combined with other measurement principles in order to gain additional information and/or in order to verify measurement results or reduce measurement errors or noise.

30

35

The human-machine interface may comprise a plurality of beacon devices which are adapted to be at least one of directly or indirectly attached to the user and held by the user. Thus, the beacon devices each may independently be attached to the user by any suitable means, such as by an appropriate fixing device. Additionally or alternatively, the user may hold and/or carry the at least one beacon device or one or more of the beacon devices in his or her hands and/or by wearing the at least one beacon device and/or a garment containing the beacon device on a body part.

40

The beacon device generally may be an arbitrary device which may be detected by the at least one detector and/or which facilitates detection by the at least one detector. Thus, as outlined above or as will be outlined in further detail below, the beacon device may be an active beacon device adapted for generating the at least one light beam to be detected by the detector, such as by having one or more illumination sources for generating the at least one light beam. Additionally or alternatively, the beacon device may fully or partially be designed as a passive beacon device, such as by providing one or more reflective elements adapted to reflect a light beam generated by a separate illumination source. The at least one beacon device may permanently or temporarily be attached to the user in a direct or indirect way and/or may be carried or held by the user. The attachment may take place by using one or more attachment means and/or by the user himself or herself, such as by the user holding the at least one beacon device by hand and/or by the user wearing the beacon device.

Additionally or alternatively, the beacon devices may be at least one of attached to an object and integrated into an object held by the user, which, in the sense of the present invention, shall be included into the meaning of the option of the user holding the beacon devices. Thus, as will be outlined in further detail below, the beacon devices may be attached to or integrated into a control element which may be part of the human-machine interface and which may be held or carried by the user, and of which the orientation may be recognized by the detector device. Thus, generally, the present invention also refers to a detector system comprising at least one detector device according to the present invention and which, further, may comprise at least one object, wherein the beacon devices are one of attached to the object, held by the object and integrated into the object. As an example, the object preferably may form a control element, the orientation of which may be recognized by a user. Thus, the detector system may be part of the human-machine interface as outlined above or as outlined in further detail below. As an example, the user may handle the control element in a specific way in order to transmit one or more items of information to a machine, such as in order to transmit one or more commands to the machine.

Alternatively, the detector system may be used in other ways. Thus, as an example, the object of the detector system may be different from a user or a body part of the user and, as an example, may be an object which moves independently from the user. As an example, the detector system may be used for controlling apparatuses and/or industrial processes, such as manufacturing processes and/or robotics processes. Thus, as an example, the object may be a machine and/or a machine part, such as a robot arm, the orientation of which may be detected by using the detector system.

The human-machine interface may be adapted in such a way that the detector device generates at least one item of information on the position of the user or of at least one body part of the user. Specifically in case a manner of attachment of the at least one beacon device to the user is known, by evaluating the position of the at least one beacon device, at least one item of information on a position and/or an orientation of the user or of a body part of the user may be gained.

The beacon device preferably is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user. As outlined above, the beacon device may fully or partially be designed as an active beacon device. Thus, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be transmitted to the detector, preferably at least one light beam having known beam properties. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

The object, which may form part of the detector system, may generally have an arbitrary shape. Preferably, the object being part of the detector system, as outlined above, may be a control element which may be handled by a user, such as manually. As an example, the control element may be or may comprise at least one element selected from the group consisting of: a glove, a jacket, a hat, shoes, trousers and a suit, a stick that may be held by hand, a bat, a club, a racket, a cane, a toy, such as a toy gun. Thus, as an example, the detector system may be part of the human-machine interface and/or of the entertainment device.

As used herein, an entertainment device is a device which may serve the purpose of leisure and/or entertainment of one or more users, in the following also referred to as one or more players. As an example, the entertainment device may serve the purpose of gaming, preferably computer gaming. Thus, the entertainment device may be implemented into a computer, a computer network or a computer system or may comprise a computer, a computer network or a computer system which runs one or more gaming software programs.

The entertainment device comprises at least one human-machine interface according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed below. The entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface. The at least one item of information may be transmitted to and/or may be used by a controller and/or a computer of the entertainment device. The at least one item of information preferably may comprise at least one command adapted for influencing the course of a game. Thus, as an example, the at least one item of information may include at least one item of information on at least one orientation of the player and/or of one or more body parts of the player, thereby allowing for the player to simulate a specific position and/or orientation and/or action required for gaming. As an example, one or more of the following movements may be simulated and communicated to a controller and/or a computer of the entertainment device: dancing; running; jumping; swinging of a racket; swinging of a bat; swinging of a club; pointing of an object towards another object, such as pointing of a toy gun towards a target.

The entertainment device as a part or as a whole, preferably a controller and/or a computer of the entertainment device, is designed to vary the entertainment function in accordance with the information. Thus, as outlined above, a course of a game might be influenced in accordance

with the at least one item of information. Thus, the entertainment device might include one or more controllers which might be separate from the evaluation device of the at least one detector and/or which might be fully or partially identical to the at least one evaluation device or which might even include the at least one evaluation device. Preferably, the at least one controller
5 might include one or more data processing devices, such as one or more computers and/or microcontrollers.

As further used herein, a tracking system is a device which is adapted to gather information on a series of past positions of the at least one object and/or at least one part of the object. Additionally,
10 the tracking system may be adapted to provide information on at least one predicted future position and/or orientation of the at least one object or the at least one part of the object. The tracking system may have at least one track controller, which may fully or partially be embodied as an electronic device, preferably as at least one data processing device, more preferably as at least one computer or microcontroller. Again, the at least one track controller may
15 fully or partially comprise the at least one evaluation device and/or may be part of the at least one evaluation device and/or may fully or partially be identical to the at least one evaluation device.

The tracking system comprises at least one detector according to the present invention, such as
20 at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time, such as by recording groups of data or data pairs, each group of data or data pair comprising at least one position information and at least one time information.
25

The tracking system may further comprise the at least one detector system according to the present invention. Thus, besides the at least one detector and the at least one evaluation device and the optional at least one beacon device, the tracking system may further comprise the object itself or a part of the object, such as at least one control element comprising the beacon
30 devices or at least one beacon device, wherein the control element is directly or indirectly attachable to or integratable into the object to be tracked.

The tracking system may be adapted to initiate one or more actions of the tracking system itself and/or of one or more separate devices. For the latter purpose, the tracking system, preferably the track controller, may have one or more wireless and/or wire-bound interfaces and/or other types of control connections for initiating at least one action. Preferably, the at least one track controller may be adapted to initiate at least one action in accordance with at least one actual position of the object. As an example, the action may be selected from the group consisting of:
35 a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.
40

As an example of application of a tracking system, the tracking system may be used for continuously pointing at least one first object to at least one second object even though the first object and/or the second object might move. Potential examples, again, may be found in industrial applications, such as in robotics and/or for continuously working on an article even though the article is moving, such as during manufacturing in a manufacturing line or assembly line. Additionally or alternatively, the tracking system might be used for illumination purposes, such as for continuously illuminating the object by continuously pointing an illumination source to the object even though the object might be moving. Further applications might be found in communication systems, such as in order to continuously transmit information to a moving object by pointing a transmitter towards the moving object.

The proposed devices and methods provide a large number of advantages over known detectors of this kind. Thus, the detector generally may avoid the shortcomings of the known prior art systems disclosed above. Specifically, the detector may avoid the use of FiP sensors, thereby allowing for e.g. using simple and cheap and commercially available semiconductor sensors such as silicon photodiodes. These photodiodes generally do not show a luminance dependency, and the method disclosed above is generally independent from the brightness of the scenery and/or the brightness of the light spot on the light beam. Consequently, a range of measurement in terms of luminance or total power of the light beam entering the detector is generally larger in the present invention as compared to many of the devices disclosed above. Further, the measurement by using the detector according to the present invention is generally independent from the target spot size, i.e. from either the size of the object, the size of a light spot projected onto the object or the size of a beacon device being one or more of attached to the object, integrated into the object or held by the object.

The detector according to the present invention may be realized as a simple device combining the functionality of distance measurement or measurement of z-coordinates, with the additional option of measuring one or more transversal coordinates, thereby integrating the functionality of a PSD.

The result of the measurement, i.e. the position determined by the detector such as the at least one longitudinal coordinate, may be rendered widely independent from the brightness of the scenery and/or the brightness of the object, the brightness of the at least one beacon device, the brightness of the at least one illumination source or the total power of the light beam propagating from the object to the detector. Further, due to this independence and wide range of measurement in terms of brightness, reflective objects or non-reflective objects may be used.

When mentioning a range of measurement, the range of measurement may both refer to a range of brightness which may be used with the detector according to the present invention, such as a range of total powers of the light beam, or may refer to a range of distances between the detector and the object which may be measured. Conventional detectors, such as according to one or more of the documents listed above, are typically limited in both ranges of measurement. The use of the quotient signal, as mentioned above, contrarily, provides a wide range of

continuously and monotonously decreasing or increasing functions which may be used to determine the longitudinal coordinate from the quotient signal. Consequently, a very wide range of measurement in terms of distance between the object and the detector is given. Similarly, due to the general independence of the quotient signal from the total power of the light beam, at least as long as no saturation of one or both of the optical sensors is reached, this also provides a very wide range of measurement in terms of brightness, i.e. in terms of total power of the light beam.

The light beam, within the detector, generally may propagate along an optical axis of the detector. The light beam, however, may also propagate in other ways than along the optical axis. As an example, an illumination light beam may be generated which propagates along the optical axis or which propagates parallel to the optical axis or at an angle to the optical axis which is different from 0° , such as an angle of 1° to 20° . Other embodiments are feasible.

Overall, in the context of the present invention, the following embodiments are regarded as preferred:

Embodiment 1: A detector for determining a position of at least one object, the detector comprising

- at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by a reflection light beam propagating from the object to the detector, wherein the sensor element is adapted to determine at least one reflection image;
- at least one evaluation device, wherein the evaluation device is adapted to select at least one reflection feature of the reflection image, wherein the evaluation device is configured for determining at least one longitudinal region of the selected reflection feature of the reflection image by evaluating a combined signal Q from the sensor signals, wherein the evaluation device is adapted to determine at least one displacement region in at least one reference image corresponding to the longitudinal region, wherein the evaluation device is adapted to match the selected reflection feature with at least one reference feature within the displacement region.

Embodiment 2: The detector according to the preceding embodiment, wherein the evaluation device is adapted to determine a displacement of the matched reference feature and the selected reflection feature, wherein the evaluation device is adapted to determine a longitudinal information of the matched feature using a predetermined relationship between a longitudinal coordinate and the displacement.

Embodiment 3: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

Embodiment 4: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for using at least one predetermined relationship between the combined signal Q and the longitudinal region for determining the longitudinal region.

Embodiment 5: The detector according to any one of the preceding embodiments, wherein the evaluation device is adapted to determine at least one longitudinal coordinate z of the selected reflection feature by evaluating the combined signal Q , wherein the longitudinal region is given by the longitudinal coordinate z and an error interval $\pm\epsilon$.

Embodiment 6: The detector according to the preceding embodiment, wherein the reference image and the reflection image are images of the object determined at different spatial positions having a fixed distance, wherein the evaluation device is adapted to determine an epipolar line in the reference image.

Embodiment 7: The detector according to the preceding embodiment, wherein the displacement region extends along the epipolar line, wherein the evaluation device is adapted to determine the reference feature along the epipolar line corresponding to the longitudinal coordinate z and to determine an extent of the displacement region along the epipolar line corresponding to the error interval $\pm\epsilon$.

Embodiment 8: The detector according to the preceding embodiment, wherein the evaluation device is configured to perform the following steps:

- Determining the displacement region for the image position of each reflection feature;
- Assigning an epipolar line to the displacement region of each reflection feature such as by assigning the epipolar line closest to a displacement region and/or within a displacement region and/or closest to a displacement region along a direction orthogonal to the epipolar line;
- Assigning and/or determining at least one reference feature to each reflection feature such as by assigning the reference feature closest to the assigned displacement region and/or within the assigned displacement region and/or closest to the assigned displacement region along the assigned epipolar line and/or within the assigned displacement region along the assigned epipolar line.

Embodiment 9: The detector according to any one of the preceding embodiments, wherein the evaluation device is adapted to match the selected feature of the reflection image with the reference feature within the displacement region by using at least one evaluation algorithm considering the determined longitudinal coordinate z .

Embodiment 10: The detector according to the preceding embodiments, wherein the evaluation algorithm is a linear scaling algorithm.

Embodiment 11: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A1 and A2 are different areas of at least one beam profile of the reflection light beam at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o.

Embodiment 12: The detector according to the preceding embodiment, wherein each of the sensor signals comprises at least one information of at least one area of the beam profile of the reflection light beam.

Embodiment 13: The detector according to any of the two preceding embodiments, wherein the beam profile is selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles.

Embodiment 14: The detector according to any one of the three preceding embodiments, wherein the light sensitive areas are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.

Embodiment 15: The detector according to the preceding embodiment, wherein the evaluation device is configured to determine the first area of the beam profile and the second area of the beam profile.

Embodiment 16: The detector according to any one of the two preceding embodiments, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile.

Embodiment 17: The detector according to any one of the two preceding embodiments, wherein the beam profile is segmented by a secant or chord passing the center of the beam profile by a given distance, whereas the first segment comprises the center information, whereas the second segment comprises essentially edge information.

Embodiment 18: The detector according to the preceding embodiment, wherein the edge information comprises information relating to a number of photons in the first area of the beam profile and the center information comprises information relating to a number of photons in the second area of the beam profile.

Embodiment 19: The detector according to any one of the two preceding embodiments, wherein the evaluation device is configured to derive the combined signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information.

Embodiment 20: The detector according to any one of the preceding embodiments, wherein the at least one evaluation device is configured for evaluating the sensor signals, by

- a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
- b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;
- c) determining at least one combined signal by combining the center signal and the sum signal; and
- d) determining the longitudinal region by evaluating the combined signal.

Embodiment 21: The detector according to the preceding embodiment, wherein the center signal is selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

Embodiment 22: The detector according to any one of the two preceding embodiments, wherein the sum signal is selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; an integral of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor

signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal.

5 Embodiment 23: The detector according to any one of the three preceding embodiments, wherein the combined signal is a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa.

10 Embodiment 24: The detector according to any one of the preceding embodiment, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the quotient signal.

15 Embodiment 25: The detector according to any one of the preceding embodiments, wherein the detector comprises at least one optical element, wherein the optical element is at least one element selected from the group consisting of: transfer device, such as at least one lens and/or at least one lens system, at least one diffractive optical element.

20 Embodiment 26: The detector according to any one of the six preceding embodiments, wherein the evaluation device is further configured for determining at least one transversal coordinate of the object by evaluating a transversal position of the at least one optical sensor having the highest sensor signal.

25 Embodiment 27: The detector according to any one of the preceding embodiments, wherein the sensor element comprises at least one CMOS sensor.

30 Embodiment 28: The detector according to any one of the preceding embodiments, wherein the detector comprises at least one illumination source, wherein the illumination source is adapted to generate at least one illumination pattern for illumination of the object.

35 Embodiment 29: The detector according to preceding embodiment, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern or a random point pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern, in particular a rotated hexagonal pattern and/or a displaced hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines.

40 Embodiment 30: The detector according to any one of the two preceding embodiments, wherein the sensor element is adapted to determine at least one reflection pattern, wherein the evaluation device is adapted to select at least one feature of the reflection pattern and to determine the

longitudinal region of the selected feature of the reflection pattern by evaluating the combined signal Q from the sensor signals.

5 Embodiment 31: The detector according to the preceding embodiment, wherein the reference image is an image of the illumination pattern at an image plane at a position of the illumination source, wherein the evaluation device is adapted to determine the displacement region in the reference image corresponding to the longitudinal region of the selected feature of the reflection pattern, wherein the evaluation device is adapted to match the selected feature of the reflection pattern with at least one feature of the reference pattern within the displacement region.

10

Embodiment 32: The detector according to any one of the four preceding embodiments, wherein the illumination source and the sensor element are separated by a fixed distance.

15 Embodiment 33: The detector according to any one of the five preceding embodiments, wherein the detector comprises at least two sensor elements each having a matrix of optical sensors.

20 Embodiment 34: The detector according to the preceding embodiment, where at least one first sensor element and at least one second sensor element are positioned at different spatial positions, wherein a relative distance between the first sensor element and the second element is fixed.

25 Embodiment 35: The detector according to any one of the two preceding embodiments, wherein the at least one first sensor element is adapted to determine at least one first reflection pattern and the at least one second sensor element is adapted to determine at least one second reflection pattern, wherein the evaluation device is adapted to select at least one image determined by the first sensor element or the second sensor element as reflection image and to select at least one image determined by the other one of the first sensor element or the second sensor element as reference image.

30 Embodiment 36: A detector system for determining a position of at least one object, the detector system comprising at least one detector according to any one of the preceding embodiments, the detector system further comprising at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object.

35

40 Embodiment 37: A human-machine interface for exchanging at least one item of information between a user and a machine, wherein the human-machine interface comprises at least one detector system according to the preceding embodiment, wherein the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user and held by the user, wherein the human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to assign to the position at least one item of information.

Embodiment 38: An entertainment device for carrying out at least one entertainment function, wherein the entertainment device comprises at least one human-machine interface according to the preceding embodiment, wherein the entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface, wherein
5 the entertainment device is designed to vary the entertainment function in accordance with the information.

Embodiment 39: A tracking system for tracking a position of at least one movable object, the tracking system comprising at least one detector system according to any one of the preceding
10 embodiments referring to a detector system, the tracking system further comprising at least one track controller, wherein the track controller is adapted to track a series of positions of the object at specific points in time.

Embodiment 40: A scanning system for determining a depth profile of a scenery, the scanning
15 system comprising at least one detector according to any of the preceding embodiments referring to a detector, the scanning system further comprising at least one illumination source adapted to scan the scenery with at least one light beam.

Embodiment 41: A camera for imaging at least one object, the camera comprising at least one
20 detector according to any one of the preceding embodiments referring to a detector.

Embodiment 42: A method for determining a position of at least one object by using at least one detector according to any one of the preceding embodiments referring to a detector, the method comprising the following steps:

- 25 - generating at least two sensor signals in response to an illumination of at least one sensor element having a matrix of optical sensors by at least one reflection light beam propagating from the object to the detector, the optical sensors each having a light-sensitive area;
- determining at least one reflection image by using the sensor element;
- 30 - selecting at least one reflection feature of the reflection image and evaluating the sensor signals by using at least one evaluation device, thereby, determining at least one longitudinal region of the selected reflection feature, wherein the evaluating comprises evaluating a combined signal Q from the sensor signals;
- determining at least one displacement region in at least one reference image corresponding to the longitudinal region;
- 35 - matching the selected reflection feature with at least one reference feature within the displacement region.

Embodiment 43: The method according to the preceding embodiment, wherein a displacement
40 of the matched reference feature and the selected reflection feature is determined, wherein a longitudinal information of the matched feature is determined using a predetermined relationship between a longitudinal coordinate and the displacement.

Embodiment 44: The method according to any one of the preceding embodiments referring to a method, wherein the deriving of the combined signal Q comprises one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

5

Embodiment 45: A use of the detector according to any one of the preceding embodiments relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a logistics application; an outdoor application; a mobile application; a communication application; a tracking application; a photography application; a machine vision application; a robotics application; a quality control application; a manufacturing application.

10

Brief description of the figures

15

Further optional details and features of the invention are evident from the description of preferred exemplary embodiments which follows in conjunction with the dependent claims. In this context, the particular features may be implemented in an isolated fashion or in combination with other features. The invention is not restricted to the exemplary embodiments. The exemplary

embodiments are shown schematically in the figures. Identical reference numerals in the individual figures refer to identical elements or elements with identical function, or elements which correspond to one another with regard to their functions.

20

Specifically, in the figures:

25

Figure 1 shows a first embodiment of a detector according to the present invention;

30

Figure 2 shows a further embodiment of the detector according to the present invention;

Figure 3 shows an embodiment of a detector system, camera, entertainment device, tracking system;

35

Figure 4 shows an embodiment of determining a longitudinal coordinate z using a line pattern;

Figures 5A to C show three embodiments of a hexagonal illumination pattern; and

40

Figure 6 shows an embodiment of a scanning system.

Detailed description of the embodiments:

Fig. 1 shows in a highly schematic fashion a first embodiment of a detector 110 for determining a position of at least one object 112. The detector 110 comprises at least one sensor element 116 having a matrix 118 of optical sensors 120. The optical sensors 120 each have a light-sensitive area 122.

The sensor element 116 may be formed as a unitary, single device or as a combination of several devices. The matrix 118 specifically may be or may comprise a rectangular matrix having one or more rows and one or more columns. The rows and columns specifically may be arranged in a rectangular fashion. However, other arrangements are feasible, such as nonrectangular arrangements. As an example, circular arrangements are also feasible, wherein the elements are arranged in concentric circles or ellipses about a center point. For example, the matrix 118 may be a single row of pixels. Other arrangements are feasible.

The optical sensors 120 of the matrix 118 specifically may be equal in one or more of size, sensitivity and other optical, electrical and mechanical properties. The light-sensitive areas 122 of all optical sensors 120 of the matrix 118 specifically may be located in a common plane, the common plane preferably facing the object 112, such that a light beam propagating from the object to the detector 110 may generate a light spot on the common plane. The light-sensitive area 122 may specifically be located on a surface of the respective optical sensor 120. Other embodiments, however, are feasible. The optical sensors 120 may comprise for example, at least one CCD and/or CMOS device. As an example, the optical sensors 120 may be part of or constitute a pixelated optical device. As an example, the optical sensors may be part of or constitute at least one CCD and/or CMOS device having a matrix of pixels, each pixel forming a light-sensitive area 122.

The optical sensors 120 specifically may be or may comprise photodetectors, preferably inorganic photodetectors, more preferably inorganic semiconductor photodetectors, most preferably silicon photodetectors. Specifically, the optical sensors 120 may be sensitive in the infrared spectral range. All of the optical sensors 120 of the matrix 118 or at least a group of the optical sensors 120 of the matrix 118 specifically may be identical. Groups of identical optical sensors 120 of the matrix 118 specifically may be provided for different spectral ranges, or all optical sensors may be identical in terms of spectral sensitivity. Further, the optical sensors 120 may be identical in size and/or with regard to their electronic or optoelectronic properties. The matrix 118 may be composed of independent optical sensors 120. Thus, a matrix 118 of inorganic photodiodes may be composed. Alternatively, however, a commercially available matrix may be used, such as one or more of a CCD detector, such as a CCD detector chip, and/or a CMOS detector, such as a CMOS detector chip.

The optical sensors 120 may form a sensor array or may be part of a sensor array, such as the above-mentioned matrix. Thus, as an example, the detector 110 may comprise an array of optical sensors 120, such as a rectangular array, having m rows and n columns, with m, n, independently, being positive integers. Preferably, more than one column and more than one row is

given, i.e. $n > 1$, $m > 1$. Thus, as an example, n may be 2 to 16 or higher and m may be 2 to 16 or higher. Preferably, the ratio of the number of rows and the number of columns is close to 1. As an example, n and m may be selected such that $0.3 \leq m/n \leq 3$, such as by choosing $m/n = 1:1$, 4:3, 16:9 or similar. As an example, the array may be a square array, having an equal number of rows and columns, such as by choosing $m=2$, $n=2$ or $m=3$, $n=3$ or the like.

The matrix 118 specifically may be a rectangular matrix having at least one row, preferably a plurality of rows, and a plurality of columns. As an example, the rows and columns may be oriented essentially perpendicular. In order to provide a wide range of view, the matrix 118 specifically may have at least 10 rows, preferably at least 50 rows, more preferably at least 100 rows. Similarly, the matrix may have at least 10 columns, preferably at least 50 columns, more preferably at least 100 columns. The matrix 118 may comprise at least 50 optical sensors 120, preferably at least 100 optical sensors 120, more preferably at least 500 optical sensors 120. The matrix 118 may comprise a number of pixels in a multi-mega pixel range. Other embodiments, however, are feasible.

In the embodiment shown in Figure 1, the detector 110 further comprises an illumination source 124. As an example, the illumination source 124 may be configured for generating an illuminating light beam for illuminating the object 112. The detector 110 may be configured such that the illuminating light beam propagates from the detector 110 towards the object 112 along an optical axis of the detector 110. For this purpose, the detector 110 may comprise at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

The illumination source 124 may be adapted to generate at least one illumination pattern for illumination of the object 112. Specifically, the illumination source 124 may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The pattern may comprise a plurality of features. The pattern may comprise an arrangement of periodic or non-periodic features. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern; at least one pattern comprising at least one pre-known feature. For example, the illumination source 124 may be adapted to generate and/or to project a cloud of points. The illumination source 124 may comprise one or more of at least one light projector; at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The illumination source 124 may comprise at least one light source adapted to generate the illumination pattern directly. The illumination source 124 may comprise the at least one light projector adapted to generate a cloud of points such that the illumination pattern may comprise a plurality of point pattern. The illumination source 124 may comprise at least one mask adapted to generate the illumination pattern from at least one light beam generated by the illumination source 124.

In the embodiment shown in Figure 1, the illumination source 124 may illuminate the at least one object 112 with the illumination pattern. The illumination pattern may comprise a plurality of points as image features. These points are illustrated as light beams 115 emerging from the illumination source 124.

5

Each optical sensor 120 is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area 122 by a reflection light beam propagating from the object 112 to the detector 110.

10 Furthermore, the sensor element 116 is adapted to determine at least one reflection image 126. The matrix 118 may comprise the reflection image 126. The reflection image 126 may comprise points as reflection features. These points result from reflection light beams 125 originating from the at least one object 112. Crossings 131 of the illumination light beams and the reflection light beams 125 correspond to possible positions 114 of the at least one object 112.

15

The detector 127 may comprise at least one transfer device 127 comprising one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam de-
20 flection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system. In particular, the transfer device 127 may comprise at least one collimating lens adapted to focus at least one object point in an image plane.

25 The detector 110 comprises at least one evaluation device 128. The evaluation device 126 is adapted to select at least one reflection feature of the reflection image 126, for example selected reflection feature 129. The evaluation device 128 may be adapted to perform at least one image analysis and/or image processing in order to identify the reflection feature. The image analysis and/or image processing may use at least one feature detection algorithm. The image
30 analysis and/or image processing may comprise one or more of the following: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency de-
35 composition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a blob analysis; applying an edge filter; applying a low-pass filter; applying a Fourier transformation; apply-
40 ing a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be deter-

mined manually by a user or may be determined automatically, such as by recognizing an object within an image generated by the optical sensors.

If the selected reflection feature 129 is matched to a corresponding reference feature, the corresponding light beams are matched and the distance of the object 112 can be calculated. For a selected reflection feature 129 and a corresponding reflection light beam, the number of corresponding illumination light beams, and thus the number of corresponding reference features 112, is reduced after determining a combined signal Q.

- 5 The evaluation device 128 is configured for determining at least one longitudinal region 130 of the selected reflection feature 129 of the reflection image by evaluating the combined signal Q from the sensor signals. The evaluation device 128 may be adapted to determine at least one longitudinal coordinate z of the selected reflection feature 129 by evaluating the combined signal Q, wherein the longitudinal region is given by the longitudinal coordinate z and an error interval $\pm \varepsilon$. Error ε may depend on measurement uncertainty of the optical sensor. For example, the error interval may be $\pm 10\%$, preferably $\pm 5\%$, more preferably $\pm 1\%$. The evaluation device 128 may be configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals. The evaluation device 128 may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal region for determining the longitudinal region. For example, the evaluation device 128 may be configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

- wherein x and y are transversal coordinates, A1 and A2 are different areas of at least one beam profile of the reflection light beam at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o. Area A1 and area A2 may differ. In particular, A1 and A2 are not congruent. Thus, A1 and A2 may differ in one or more of the shape or content. The beam profile may be a transverse intensity profile of the light beam. The beam profile may be a cross section of the light beam. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles. Generally the beam profile is dependent on luminance L(z_o) and beam shape S(x,y;z_o), E(x,y;z_o)=L•S. Thus, by deriving the combined signal it may allow determining the longitudinal coordinate independent from luminance. In addition, using the combined signal allows determination of the distance z_o independent from the object size. Thus, the combined signal allows determination of the distance z_o independent from the material properties and/or reflective properties and/or scattering properties of the object and independent from alterations of the light source such as by manufacturing precision, heat, water, dirt, damages on the lens, or the like.

Each of the sensor signals may comprise at least one information of at least one area of the beam profile of the light beam. The light-sensitive areas 122 may be arranged such that a first sensor signal comprises information of a first area of the beam profile and a second sensor signal comprises information of a second area of the beam profile. The first area of the beam profile and second area of the beam profile may be one or both of adjacent or overlapping regions. The first area of the beam profile and the second area of the beam profile may be not congruent in area.

The evaluation device 128 may be configured to determine and/or to select the first area of the beam profile and the second area of the beam profile. The first area of the beam profile may comprise essentially edge information of the beam profile and the second area of the beam profile may comprise essentially center information of the beam profile. The beam profile may have a center, i.e. a maximum value of the beam profile and/or a center point of a plateau of the beam profile and/or a geometrical center of the light spot, and falling edges extending from the center. The second region may comprise inner regions of the cross section and the first region may comprise outer regions of the cross section. Preferably, the center information has a proportion of edge information of less than 10 %, more preferably of less than 5%, most preferably the center information comprises no edge content. The edge information may comprise information of the whole beam profile, in particular from center and edge regions. The edge information may have a proportion of center information of less than 10 %, preferably of less than 5%, more preferably the edge information comprises no center content. At least one area of the beam profile may be determined and/or selected as second area of the beam profile if it is close or around the center and comprises essentially center information. At least one area of the beam profile may be determined and/or selected as first area of the beam profile if it comprises at least parts of the falling edges of the cross section. For example, the whole area of the cross section may be determined as first region. The first area of the beam profile may be area A2 and the second area of the beam profile may be area A1. Similarly, the center signal and edge signal may also be determined by using segments of the beam profile such as circular segments of the beam profile. For example, the beam profile may be divided into two segments by a secant or a chord that does not pass the center of the beam profile. Thus, one segment will essentially contain edge information, while the other segment will contain essentially center information. For example, to further reduce the amount of edge information in the center signal, the edge signal may further be subtracted from the center signal.

The edge information may comprise information relating to a number of photons in the first area of the beam profile and the center information may comprise information relating to a number of photons in the second area of the beam profile. The evaluation device 128 may be adapted for determining an area integral of the beam profile. The evaluation device 128 may be adapted to determine the edge information by integrating and/or summing of the first area. The evaluation device 128 may be adapted to determine the center information by integrating and/or summing of the second area. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of edge and center signals may be

replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

- 5 Additionally or alternatively, the evaluation device 128 may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized, for example, by replacing the area integrals in the combined signal Q by a line integral along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or
10 cuts may result in improved distance information.

For example, the evaluation device 128 may be configured for evaluating the sensor signals, by

- a) determining at least one optical sensor 120 having the highest sensor signal and forming at least one center signal;
- 15 b) evaluating the sensor signals of the optical sensors 120 of the matrix 118 and forming at least one sum signal;
- c) determining at least one combined signal by combining the center signal and the sum signal; and
- d) determining the at least one longitudinal coordinate z of the selected feature by evaluating
20 the combined signal.

- For example, the center signal may be the signal of the at least one optical sensor 118 having the highest sensor signal out of the plurality of sensor signals generated by the optical sensors 120 of the entire matrix 118 or of a region of interest within the matrix 118, wherein the region of
25 interest may be predetermined or determinable within an image generated by the optical sensors of the matrix 118. The center signal may arise from a single optical sensor 120 or from a group of optical sensors 120, wherein, in the latter case, as an example, the sensor signals of the group of optical sensors 120 may be added up, integrated or averaged, in order to determine the center signal. The group of optical sensors 120 from which the center signal arises
30 may be a group of neighboring optical sensors, such as optical sensors 120 having less than a predetermined distance from the actual optical sensor having the highest sensor signal, or may be a group of optical sensors generating sensor signals being within a predetermined range from the highest sensor signal. The group of optical sensors 120 from which the center signal arises may be chosen as large as possible in order to allow maximum dynamic range. The
35 evaluation device 128 may be adapted to determine the center signal by integration of the plurality of sensor signals, for example the plurality of optical sensors around the optical sensor having the highest sensor signal.

- The determination of the center signal may be performed electronically, since a comparison of
40 sensor signals is fairly simply implemented by conventional electronics, or may be performed fully or partially by software. The detection of the center of the light spot, i.e. the detection of the center signal and/or of the at least one optical sensor from which the center signal arises, may be performed fully or partially electronically or fully or partially by using one or more software

algorithms. Specifically, the evaluation device 128 may comprise at least one center detector for detecting the at least one highest sensor signal and/or for forming the center signal. The center detector specifically may fully or partially be embodied in software and/or may fully or partially be embodied in hardware. The center detector may fully or partially be integrated into the at
5 least one sensor element and/or may fully or partially be embodied independently from the sensor element.

Specifically, the center signal may be selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance
10 from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor 120 having the highest sensor signal and a predetermined group of neighboring optical sensors 120; a sum of sensor signals from a group of optical sensors 120 containing the optical sensor 120 having the highest sensor signal and a predetermined group of neighboring optical sensors 120; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors 120 containing the optical sensor 120 having the highest sensor signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.
20

For example, the sum signal may be derived by adding up the sensor signals, integrating over the sensor signals or averaging over the sensor signals of the entire matrix 118 or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable
25 within an image generated by the optical sensors 120 of the matrix 118. When adding up, integrating over or averaging over the sensor signals, the actual optical sensors 120 from which the sensor signal is generated may be left out of the adding, integration or averaging or, alternatively, may be included into the adding, integration or averaging. The evaluation device 128 may be adapted to determine the sum signal by integrating signals of the entire matrix 118, or of the region of interest within the matrix 118. Further, when trapezoid beam profiles may be assumed, the determination of edge and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by
30 geometric considerations.
35

The sum signal may be derived from all sensor signals of the matrix 118, from the sensor signals within a region of interest or from one of these possibilities with the sensor signals arising from the optical sensors 120 contributing to the center signal excluded. In every case, a reliable
40 sum signal may be generated which may be compared with the center signal reliably, in order to determine the longitudinal coordinate. Generally, the sum signal may be selected from the group consisting of: an average over all sensor signals of the matrix 118; a sum of all sensor signals of the matrix 118; an integral of all sensor signals of the matrix 118; an average over all

sensor signals of the matrix 118 except for sensor signals from those optical sensors 120 contributing to the center signal; a sum of all sensor signals of the matrix 118 except for sensor signals from those optical sensors 120 contributing to the center signal; an integral of all sensor signals of the matrix 118 except for sensor signals from those optical sensors 120 contributing to the center signal; a sum of sensor signals of optical sensors 120 within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor 120 having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor 120 having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors 120 being located within a predetermined range from the optical sensor 120 having the highest sensor signal. Other options, however, exist. The summing may be performed fully or partially in software and/or may be performed fully or partially in hardware. A summing is generally possible by purely electronic means which, typically, may easily be implemented into the detector. Thus, in the art of electronics, summing devices are generally known for summing two or more electrical signals, both analogue signals and digital signals. Thus, the evaluation device 128 may comprise at least one summing device for forming the sum signal. The summing device may fully or partially be integrated into the sensor element or may fully or partially be embodied independently from the sensor element. The summing device may fully or partially be embodied in one or both of hardware or software.

The combined signal may be a signal which is generated by combining the center signal and the sum signal. Specifically, the combination may include one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa. Additionally or alternatively, the combined signal may comprise an arbitrary signal or signal combination which contains at least one item of information on a comparison between the center signal and the sum signal. The evaluation device 128 may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between the sensor signals. In particular, the evaluation device 128 may be configured to determine the at least one coordinate z of the by using at least one known, determinable or predetermined relationship between a quotient signal derived from the sensor signals and the longitudinal coordinate.

The comparison between the center signal and the sum signal specifically may be performed by forming one or more quotient signals. Thus, generally, the combined signal may be a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of the center signal and a linear combination of the sum signal and the center signal or vice versa; forming a quotient of the sum signal and a linear combination of the sum signal and the center signal or vice versa; forming a

quotient of an exponentiation of the center signal and an exponentiation of the sum signal or vice versa. Other options, however, exist. The evaluation device 128 may be configured for forming the one or more quotient signals. The evaluation device 128 may further be configured for determining the at least one longitudinal coordinate by evaluating the at least one quotient
5 signal.

The evaluation device 128 specifically may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal coordinate, in order to determine the at least one longitudinal coordinate. Thus, due to the reasons disclosed above and
10 due to the dependency of the properties of the light spot on the longitudinal coordinate, the combined signal Q typically is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, a simple quotient of the sensor signal s_{center} and the sum signal s_{sum} $Q = s_{\text{center}}/s_{\text{sum}}$ may be a monotonously decreasing function of the distance. Without wishing to be bound by this theory, it is believed that this is
15 due to the fact that, in the preferred setup described above, both the center signal s_{center} and the sum signal s_{sum} decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, the center signal s_{center} decreases more rapidly than the sum signal s_{sum} , since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. The
20 quotient of the center signal and the sum signal, thus, continuously decreases with increasing diameter of the light beam or diameter of the light spot on the light-sensitive areas of the optical sensors of the matrix. The quotient, further, is typically independent from the total power of the light beam, since the total power of the light beam forms a factor both in the center signal and in the sum sensor signal. Consequently, the combined signal Q may form a secondary signal which provides a unique and unambiguous relationship between the center signal and the sum signal and the size or diameter of the light beam. Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship between the center signal and the sum signal on the one hand and the longitudinal coordinate on the other hand may exist. For the latter, reference e.g. may be made to one or more of the above-mentioned prior art documents, such as WO 2014/097181 A1. The predetermined relationship may be determined by analytical considerations, such as by assuming a linear combination of Gaussian light beams,
25 by empirical measurements, such as measurements measuring the combined signal and/or the center signal and the sum signal or secondary signals derived thereof as a function of the longitudinal coordinate of the object, or both.
30

The evaluation device 128 may be configured for using at least one predetermined relationship
40 between the combined signal and the longitudinal coordinate. The predetermined relationship may be one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship. The evaluation device 128 may comprise at least one data storage device for storing the predetermined relationship, such as a lookup list or a lookup table.

The sensor element 116 may be adapted to determine at least one reflection pattern. The reflection pattern may comprise at least one feature corresponding to at least one feature of the illumination pattern. The reflection pattern may comprise, in comparison to the illumination pattern, at least one distorted pattern, wherein the distortion depends on the distance of the object, such as surface properties of the object. The evaluation device 128 may be adapted to select at least one feature of the reflection pattern and to determine the longitudinal region of the selected feature of the reflection pattern by evaluating the combined signal Q from the sensor signals, as described above.

The evaluation device 128 is adapted to determine at least one displacement region 132 in at least one reference image 134 corresponding to the longitudinal region 130. The longitudinal region corresponds to the displacement region 132. The reference image 134 and the reflection image 126 may be images of the object 112 determined at different spatial positions having a fixed distance b, also called baseline. The evaluation device 128 may be adapted to determine an epipolar line 136 in the reference image 134. Relative position of the reference image 134 and reflection image 126 may be known. For example, relative position of the reference image 134 and reflection image 126 may be stored within at least one storage unit of the evaluation device 128. The evaluation device 128 may be adapted to determine a straight line 138 extending from the selected reflection feature 129 of the reflection image 126. The straight line 138 may comprise possible object positions 114. The straight line 138 and the baseline b span an epipolar plane 140. As the reference image 134 is determined at a different relative position from the reflection image, the corresponding reference features may be imaged on the epipolar line 136 in the reference image 134.

For example, in the embodiment shown in Figure 1, the reference image 134 may be an image of the illumination pattern at an image plane at a position of the illumination source 124. The evaluation device 128 may be adapted to determine the displacement region 132 in the reference image 134 corresponding to the longitudinal region 130 of the selected feature 129 of the reflection pattern. The evaluation device 128 may be adapted to match the selected feature 129 of the reflection pattern with at least one feature of the reference pattern within the displacement region 132. The illumination source 124 and the sensor element 116 may be separated by a fixed distance.

The displacement region 132 may extend along the epipolar line 136. The evaluation device 128 may be adapted to determine the reference feature along the epipolar line 136 corresponding to the longitudinal coordinate z and to determine an extent of the displacement region 132 along the epipolar line 136 corresponding to the error interval $\pm\epsilon$. The evaluation device 128 is adapted to match the selected reflection feature 129 with at least one reference feature within the displacement region 132. The evaluation device 128 may be adapted to match the selected feature of the reflection image with the reference feature within the displacement region 132 by using at least one evaluation algorithm considering the determined longitudinal coordinate z. The evaluation algorithm may be a linear scaling algorithm.

The evaluation device 128 may be adapted to determine a displacement of the matched reference feature and the selected reflection feature 129. The evaluation device 128 may be adapted to determine a longitudinal information of the matched feature using a predetermined relationship between a longitudinal coordinate and the displacement. For example, the longitudinal information may be a distance value. The evaluation device 128 may be adapted to determine the pre-determined relationship by using triangulation methods. In case position of the selected reflection feature 129 in the reflection image 126 and position of the matched reference feature and/or relative displacement of the selected reflection feature and the matched reference feature are known, a longitudinal coordinate of the corresponding object feature 114 may be determined by triangulation. Thus, the evaluation device 128 may be adapted to select, for example subsequent and/or column by column, a reflection feature and to determine for each potential position of the reference feature the corresponding distance value using triangulation. For example, Figure 1 shows possible projection lines resulting in reflection features in the reflection image 126 and corresponding to reference features in the reference image 134. In addition, intersection points of these lines are shown corresponding to object positions. Displacement and corresponding distance value may be stored in at least one storage device of the evaluation device. The evaluation device 128 may, as an example, comprise at least one data processing device, such as at least one processor, at least one DSP, at least one FPGA and/or at least one ASIC. Further, for storing the at least one predetermined or determinable relationship between the longitudinal coordinate z and the displacement, the at least one data storage device may be provided, such as for providing one or more look-up tables for storing the predetermined relationship.

In Figure 2, an embodiment of the detector 110 is shown, wherein the detector 110 may comprise at least two sensor elements 116 each having a matrix 118 of optical sensors 120. At least one first sensor element 142 and at least one second sensor element 144 may be positioned at different spatial positions. A relative distance b between the first sensor element 142 and the second element 144 may be fixed. The at least one first sensor element 142 may be adapted to determine at least one first reflection pattern and the at least one second sensor element 144 may be adapted to determine at least one second reflection pattern. The evaluation device 128 may be adapted to select at least one image determined by the first sensor element 142 or the second sensor element 144 as reflection image and to select at least one image determined by the other one of the first sensor element 142 or the second sensor element 144 as reference image. In Figure 2, the image of the first sensor element 142 is selected as reflection image 126, whereas the image of the second sensor element 144 is selected as reference image 134. The evaluation device 128 may be adapted to select the at least one reflection feature in the reflection pattern and to determine the longitudinal region 130 of the selected feature by evaluating the combined signal Q from the sensor signals, as outlined with respect to Figure 1. The evaluation device 128 may be adapted to determine the displacement region 132 in the reference image 134 corresponding to the longitudinal region 120 of the selected feature 129 of the reflection pattern. The evaluation device 128 may be adapted to match the selected feature 129

of the reflection pattern with at least one feature of the reference pattern within the displacement region 132, as outlined with respect to Figure 1.

Using the combined sensor signal allows to estimate distances, such as the longitudinal coordinate z within the error interval. By determining the displacement region 132 corresponding to the estimated longitudinal coordinate and the corresponding error interval allows to reduce possible number of solutions along the epipolar line 136 significantly. The number of solutions may even be reduced to one. Subsequent matching of the selected reflection feature and reference feature may enhance accuracy. Determining of the longitudinal coordinate z and the error interval may be performed during a pre-evaluation before matching the selected reflection feature 129 and reference feature. This may allow reducing the computational demand such that it is possible to significantly reduce costs and to allow a use in mobile device or outdoor devices, where battery life or ventilation or heat management is an issue. Furthermore, generally in triangulation systems the baseline has to be large in order to detect large distances. Pre-evaluation of the longitudinal coordinate z and error interval using the combined sensor signal and subsequent matching of the selected reflection feature 129 and reference feature may allow using short baselines such that it may be possible to provide a compact device. Furthermore, pre-evaluation of the longitudinal coordinate z and error interval using the combined sensor signal and subsequent matching of the selected reflection feature and reference feature may enhance accuracy in comparison the triangulation systems. Furthermore, it may be possible to use denser pattern in order to enhance further resolution or to use a less dense pattern in order to increase power per point.

Figure 3 shows, in a highly schematic illustration, an exemplary embodiment of the detector 110, for example according to the embodiment shown in Figure 2. The detector 110 specifically may be embodied as a camera 146 and/or may be part of a camera 146. The camera 146 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible. Fig. 3 further shows an embodiment of a detector system 148, which, besides the at least one detector 110, comprises one or more beacon devices 150, which, in this example, may be attached and/or integrated into an object 112, the position of which shall be detected by using the detector 110. Fig. 3 further shows an exemplary embodiment of a human-machine interface 152, which comprises the at least one detector system 148 and, further, an entertainment device 154, which comprises the human-machine interface 152. The figure further shows an embodiment of a tracking system 156 for tracking a position of the object 112, which comprises the detector system 148. The components of the devices and systems shall be explained in further detail below.

Fig. 3 further shows an exemplary embodiment of a scanning system 158 for scanning a scenery comprising the object 112, such as for scanning the object 112 and/or for determining at least one position of the at least one object 112. The scanning system 158 comprises the at least one detector 110, and, further, optionally, the at least one illumination source 124 as well as, optionally, at least one further illumination source, not depicted here. The illumination source

124, generally, is configured to emit at least one illumination light beam, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 150 and/or on a surface of the object 112. The scanning system 158 may be designed to generate a profile of the scenery including the object 112 and/or a profile of the object 112, and/or may be designed to generate at least one item of information about the distance between the at least one dot and the scanning system 158, specifically the detector 110, by using the at least one detector 110.

As outlined above, an exemplary embodiment of the detector 110 which may be used in the setup of Fig. 3 is shown in Fig. 2. Thus, the detector 110, besides the optical sensors 120 comprises at least one evaluation device 128, having e.g. at least one divider 160 and/or the at least one position evaluation device 162, as symbolically depicted in Fig. 3. The components of the evaluation device 128 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 110. Besides the possibility of fully or partially combining two or more components, one or more of the optical sensors 120 and one or more of the components of the evaluation device 128 may be interconnected by one or more connectors 164 and/or by one or more interfaces, as symbolically depicted in Fig. 3. Further, the one or more connectors 164 may comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 164, the evaluation device 128 may fully or partially be integrated into one or both of the optical sensors 120 and/or into a housing 166 of the detector 110. Additionally or alternatively, the evaluation device 128 may fully or partially be designed as a separate device.

In this exemplary embodiment, the object 112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 168, the position of which may be manipulated by a user 170. As an example, the object 112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 112 are possible. Further, the user 170 himself or herself may be considered as the object 112, the position of which shall be detected.

As outlined above, the detector 110 comprises optical sensors 120. The optical sensors 120 may be located inside the housing 166. Further, the detector 110 may comprise the at least one transfer device 127 such as one or more optical systems, preferably comprising one or more lenses. An opening 172 inside the housing 166, which, preferably, is located concentrically with regard to an optical axis 174 of the detector 110, preferably defines a direction of view 176 of the detector 110. A coordinate system 178 may be defined, in which a direction parallel or anti-parallel to the optical axis 174 may be defined as a longitudinal direction, whereas directions perpendicular to the optical axis 174 may be defined as transversal directions. In the coordinate system 178, symbolically depicted in Fig. 3, a longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other types of coordinate systems are feasible, such as non-Cartesian coordinate systems.

One or more light beams 180, such as light beams of the illumination pattern, are propagating from the object 112 and/or from one or more of the beacon devices 150, towards the detector 110. The detector 110 is configured for determining a position of the at least one object 112. In case no illumination source 124 is used, the beacon devices 150 and/or at least one of these
5 beacon devices 150 may be or may comprise active beacon devices with an integrated illumination source such as a light-emitting diode. Alternatively, ambient light sources may be used.

The light beam 180, for example generated by the illumination source 124 such as the at least one illumination pattern, may be directed towards the object by using one or more optical elements. The object 112 may in response to the illumination generate the at least one reflection
10 light beam 182. For details of the evaluation, reference may be made to Fig. 1 above.

As outlined above, the determination of the position of the object 112 and/or a part thereof by using the detector 110 may be used for providing a human-machine interface 152, in order to
15 provide at least one item of information to a machine 184. In the embodiments schematically depicted in Fig. 3, the machine 184 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 128 may even be fully or partially integrated into the machine 184, such as into the computer.

As outlined above, Fig. 3 also depicts an example of a tracking system 156, configured for tracking the position of the at least one object 112 and/or of parts thereof. The tracking system 156 comprises the detector 110 and at least one track controller 186. The track controller 186 may be adapted to track a series of positions of the object 112 at specific points in time. The track controller 186 may be an independent device and/or may be fully or partially integrated
20 into the machine 184, specifically the computer, as indicated in Fig. 3 and/or into the evaluation device 128.

Similarly, as outlined above, the human-machine interface 152 may form part of an entertainment device 154. The machine 184, specifically the computer, may also form part of the entertainment device 154. Thus, by means of the user 170 functioning as the object 112 and/or by
30 means of the user 170 handling a control device functioning as the object 112, the user 170 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer.

Referring to Figure 4, the detector 110 such as the detector as described with respect to Figures 1 to 3 may be adapted to determine depth information, in particular absolute depth information, from a radiance ratio of at least two asymmetric regions of a light beam profile on the at least two optical sensors 120. For example, the detector 110 may comprise a plurality of optical sensors arranged in the matrix 118. The detector 110 may be adapted to determine depth information from a radiance ratio of at least two asymmetric regions within an enclosed, in particular, defocused beam profile captured by a single matrix of optical sensors such as a CMOS detector. In particular, the detector 110 may be adapted to determine the depth information using the radiance ratio independent of a certain object size range. As outlined above, this principle is
40

called Distance by Photon Ratio (DPR). In one embodiment, the light beam 180 may illuminate the sensor element 116 with at least one pattern comprising at least one feature point. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. The evaluation device 128 may be configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

- wherein x and y are transversal coordinates, A1 and A2 are areas of the beam profile at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors. The central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

In the embodiment shown in Figure 4, the reflection light beam 182 propagating from the object 112 to the detector 110 may illuminate the matrix 118 with at least one line pattern 188. The line pattern 188 may be generated by the object 112 for example in response to an illumination by the at least one illumination source 124 with an illumination pattern comprising at least one illumination line pattern. A1 may correspond to an area with a full line width of the line pattern 188 in the matrix 118. The line pattern 188 in the matrix 118 may be widened and/or displaced compared to the line pattern of the illumination pattern such that a line width in the matrix 118 is increased. In particular, the line width of the line pattern 188 in the matrix 118 may change from one column to another column. A2 may be a central area of the line pattern 188 in the matrix 118. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern 188 may be segmented in the matrix 118. Each of the columns may comprise center information of intensity in the central area of the line pattern 188 and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern 188.

35

Figures 5A to C show three embodiments of a hexagonal illumination pattern. The illumination source 124 may be adapted to generate at least one illumination pattern for illuminating the object 112. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. Specifically, the illumination source 124 may comprise at least one laser

and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The illumination pattern may comprise at least one feature such as a point or symbol. The illumination pattern may comprise a plurality of features. The illumination pattern may com-
5 prise an arrangement of periodic or non-periodic features. The illumination pattern may be generated by ambient light, such as by at least one ambient light source, or by the at least one illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern, a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one qua-
10 siperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines. For example, the illumination source may be adapted to generate and/or to
15 project a cloud of points. The illumination pattern may comprise regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern, or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that hexagonal pattern may be preferred. A distance between two features of the illumination pattern and/or an area of the at least one illumination feature
20 may depend on the circle of confusion in the image.

The illumination features of the illumination pattern may be arranged such that only few reference features are positioned on an epipolar line. As shown in Figure 5A, the illumination pattern may comprise at least one hexagonal pattern, wherein the individual points are positioned on
25 epipolar lines 190. As shown in Figure 5B, the illumination pattern may comprise at least one hexagonal pattern, wherein the pattern is rotated relative to the baseline. Such a positioning of the illumination features allows enhancing distance between the individual points on each epipolar line. For example as shown in Figure 5C, the illumination pattern may comprise at least one displaced hexagonal pattern, wherein individual points of the hexagonal pattern are dis-
30 placed by a random distance from the regular position, for example orthogonal to the epipolar line of the point. The displacement of the individual points may be smaller than half of the distance between two parallel epipolar lines, preferably smaller than one fourth of the distance between two parallel epipolar lines. The displacement of the individual points may be as such that two points are not displaced above each other

35 Figure 6 shows an embodiment of a scanning system 158. The scanning system 158 may be adapted as a line scanning device. In particular, the scanning system 158 may comprise at least one sensor line or row of optical sensors 120. Furthermore, the scanning system 158 may comprise the at least one transfer device 127 and the at least one illumination source 124. Triangu-
40 lation systems require a sufficient baseline, however due to the baseline in the near field no detection may be possible. Near field detection may be possible if the light spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. Thus, in triangulation systems, the non-

zero baseline will always lead to a substantial reduction in the measurement range, in the near field, and/or in the far field. Reducing the baseline as possible with the detector according to the present invention will thus always increase the measurement range. Further, these near field and far field problems can be overcome by using the scanning system 158 of Figure 6. The scanning system 158 may be adapted to detect a plurality of light beams 182 propagating from the object 112 to the scanning system 158 on the CMOS line. The light beams 182 may be generated at different position on the object 112 or by movement of the object 112. The scanning system 158 may be adapted to determine at least one longitudinal coordinate for each of the light points by determining the combined signal Q as described above.

Patent claims

1. A detector (110) for determining a position of at least one object (112), the detector (110) comprising
 - 5 - at least one sensor element (116) having a matrix (118) of optical sensors (120), the optical sensors (120) each having a light-sensitive area (122), wherein each optical sensor (120) is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area (122) by a reflection light beam (182) propagating from the object (112) to the detector (110), wherein the sensor element (116) is adapted to determine at least one reflection image (126);
 - 10 - at least one evaluation device (128), wherein the evaluation device (128) is adapted to select at least one reflection feature of the reflection image (126), wherein the evaluation device (128) is configured for determining at least one longitudinal region (130) of the selected reflection feature of the reflection image (134) by evaluating a combined signal Q from the sensor signals, wherein the evaluation device (128) is adapted to determine at least one displacement region (132) in at least one reference image (134) corresponding to the longitudinal region (130), wherein the evaluation device (128) is adapted to match the selected reflection feature with at least one reference feature within the displacement region (132).
 - 15
 - 20
2. The detector (110) according to the preceding claim, wherein the evaluation device (128) is adapted to determine a displacement of the matched reference feature and the selected reflection feature, wherein the evaluation device (128) is adapted to determine a longitudinal information of the matched feature using a predetermined relationship between a longitudinal coordinate and the displacement.
- 25
3. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.
- 30
4. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is configured for using at least one predetermined relationship between the combined signal Q and the longitudinal region for determining the longitudinal region.
- 35
5. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is adapted to determine at least one longitudinal coordinate z of the selected reflection feature by evaluating the combined signal Q, wherein the longitudinal region (130) is given by the longitudinal coordinate z and an error interval $\pm\epsilon$.
- 40
6. The detector (110) according any one of the preceding claims, wherein the reference image (134) and the reflection image (126) are images of the object determined at different spatial

positions having a fixed distance, wherein the evaluation device (128) is adapted to determine an epipolar line (136) in the reference image (134).

7. The detector (110) according to the two preceding claims, wherein the displacement region (132) extends along the epipolar line (136), wherein the evaluation device (128) is adapted to determine the reference feature along the epipolar line (136) corresponding to the longitudinal coordinate z and to determine an extent of the displacement region (132) along the epipolar line (136) corresponding to the error interval $\pm\epsilon$.
8. The detector (110) according to the preceding claim, wherein the evaluation device (128) is configured to perform the following steps:
 - Determining the displacement region for the image position of each reflection feature;
 - Assigning an epipolar line to the displacement region of each reflection feature such as by assigning the epipolar line closest to a displacement region and/or within a displacement region and/or closest to a displacement region along a direction orthogonal to the epipolar line;
 - Assigning and/or determining at least one reference feature to each reflection feature such as by assigning the reference feature closest to the assigned displacement region and/or within the assigned displacement region and/or closest to the assigned displacement region along the assigned epipolar line and/or within the assigned displacement region along the assigned epipolar line.
9. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is adapted to match the selected feature of the reflection image (126) with the reference feature within the displacement region (132) by using at least one evaluation algorithm considering the determined longitudinal coordinate z , wherein the evaluation algorithm is a linear scaling algorithm.
10. The detector (110) according to any one of the preceding claims, wherein the evaluation device (128) is configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A_1 and A_2 are different areas of at least one beam profile of the reflection light beam (182) at the sensor position, and $E(x, y, z_o)$ denotes the beam profile given at the object distance z_o , wherein each of the sensor signals comprises at least one information of at least one area of the beam profile of the reflection light beam.

11. The detector (110) according to the preceding claim, wherein the light-sensitive areas (122) are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.
12. The detector (110) according to the preceding claim, wherein the evaluation device (128) is configured to determine the first area of the beam profile and the second area of the beam profile, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile, wherein the edge information comprises information relating to a number of photons in the first area of the beam profile and the center information comprises information relating to a number of photons in the second area of the beam profile.
13. The detector (110) according to any one of the preceding claims, wherein the at least one evaluation device (128) is configured for evaluating the sensor signals, by
- a) determining at least one optical sensor (120) having the highest sensor signal and forming at least one center signal;
 - b) evaluating the sensor signals of the optical sensors (120) of the matrix (118) and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and
 - d) determining the longitudinal region by evaluating the combined signal.
14. The detector (110) according to the preceding claim, wherein the combined signal is a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa.
15. The detector (110) according to any one of the preceding claims, wherein the detector (110) comprises at least one illumination source (124), wherein the illumination source (124) is adapted to generate at least one illumination pattern for illumination of the object (112), wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern; at least one pattern comprising at least one pre-known feature.
16. The detector (110) according to the preceding claim, wherein the sensor element (116) is adapted to determine at least one reflection pattern, wherein the evaluation device (128) is adapted to select at least one feature of the reflection pattern and to determine the longitudinal region (130) of the selected feature of the reflection pattern by evaluating the combined signal Q from the sensor signals.

17. The detector (110) according to the preceding claim, wherein the reference image (134) is an image of the illumination pattern at an image plane at a position of the illumination source (124), wherein the evaluation device (128) is adapted to determine the displacement region (132) in the reference image (134) corresponding to the longitudinal region (130) of the selected feature of the reflection pattern, wherein the evaluation device (128) is adapted to match the selected feature of the reflection pattern with at least one feature of the reference pattern within the displacement region (132).
18. The detector (110) according to any one of the three preceding claims, wherein the detector (110) comprises at least two sensor elements (116) each having a matrix (118) of optical sensors (120), where at least one first sensor element (142) and at least one second sensor element (144) are positioned at different spatial positions, wherein a relative distance between the first sensor element (142) and the second element (144) is fixed, wherein the at least one first sensor element (142) is adapted to determine at least one first reflection pattern and the at least one second sensor element (144) is adapted to determine at least one second reflection pattern, wherein the evaluation device (128) is adapted to select at least one image determined by the first sensor element (142) or the second sensor element (144) as reflection image (126) and to select at least one image determined by the other one of the first sensor element (142) or the second sensor element (144) as reference image (134).
19. A detector system (148) for determining a position of at least one object (112), the detector system (148) comprising at least one detector (110) according to any one of the preceding claims, the detector system (148) further comprising at least one beacon device (150) adapted to direct at least one light beam towards the detector (110), wherein the beacon device (150) is at least one of attachable to the object (112), holdable by the object (112) and integratable into the object (112).
20. A human-machine interface (152) for exchanging at least one item of information between a user (170) and a machine (184), wherein the human-machine interface (152) comprises at least one detector system (148) according to the preceding claim, wherein the at least one beacon device (150) is adapted to be at least one of directly or indirectly attached to the user (170) and held by the user (170), wherein the human-machine interface (152) is designed to determine at least one position of the user (170) by means of the detector system (148), wherein the human-machine interface (152) is designed to assign to the position at least one item of information.
21. An entertainment device (154) for carrying out at least one entertainment function, wherein the entertainment device (154) comprises at least one human-machine interface (152) according to the preceding claim, wherein the entertainment device (154) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (152), wherein the entertainment device (154) is designed to vary the entertainment function in accordance with the information.

22. A tracking system (156) for tracking a position of at least one movable object (112), the tracking system (156) comprising at least one detector system (148) according to any one of the preceding claims referring to a detector system (148), the tracking system (156) further comprising at least one track controller (186), wherein the track controller (186) is adapted to track a series of positions of the object (112) at specific points in time.
23. A scanning system (158) for determining a depth profile of a scenery, the scanning system comprising at least one detector (110) according to any of the preceding claims referring to a detector, the scanning system (158) further comprising at least one illumination source (124) adapted to scan the scenery with at least one light beam.
24. A camera (146) for imaging at least one object (112), the camera (146) comprising at least one detector (110) according to any one of the preceding claims referring to a detector.
25. A method for determining a position of at least one object (112) by using at least one detector (110) according to any one of the preceding claims referring to a detector, the method comprising the following steps:
- generating at least two sensor signals in response to an illumination of at least one sensor element (116) having a matrix (118) of optical sensors (120) by at least one reflection light beam (182) propagating from the object (112) to the detector (110), the optical sensors (120) each having a light-sensitive area (122);
 - determining at least one reflection image (126) by using the sensor element (116);
 - selecting at least one reflection feature of the reflection image (126) and evaluating the sensor signals by using at least one evaluation device (128), thereby, determining at least one longitudinal region (130) of the selected reflection feature, wherein the evaluating comprises evaluating a combined signal Q from the sensor signals;
 - determining at least one displacement region (132) in at least one reference image (134) corresponding to the longitudinal region (130);
 - matching the selected reflection feature with at least one reference feature within the displacement region (132).
26. A use of the detector (110) according to any one of the preceding claims relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a logistics application; a tracking application; an outdoor application; a mobile application; a communication application; a photography application; a machine vision application; a robotics application; a quality control application; a manufacturing application;

(54) Title: DETECTOR FOR OPTICALLY DETECTING AT LEAST ONE OBJECT

FIG.1A

(57) Abstract: A detector (110) for determining a position of at least one object (112) is proposed. The detector (110) comprises: - at least one transversal optical sensor (130), the transversal optical sensor (130) being adapted to determine a transversal position of at least one light beam (138) traveling from the object (112) to the detector (110), the transversal position being a position in at least one dimension perpendicular to an optical axis (116) of the detector (110), the transversal optical sensor (130) being adapted to generate at least one transversal sensor signal; - at least one longitudinal optical sensor (132), wherein the longitudinal optical sensor (132) has at least one sensor region (136), wherein the longitudinal optical sensor (132) is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region (136) by the light beam (138), wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam (138) in the sensor region (136); - at least one evaluation device (142), wherein the evaluation device (142) is designed to generate at least one item of information on a transversal position of the object (112) by evaluating the transversal sensor signal and to generate at least one item of information on a longitudinal position of the object (112) by evaluating the longitudinal sensor signal.

Detector for optically detecting at least one objectDescription5 Field of the invention

The invention relates to a detector for determining a position of at least one object. Furthermore, the invention relates to a human-machine interface, an entertainment device, a tracking system and a camera. Furthermore, the invention relates to a method for optically detecting a position
10 of at least one object and to various uses of the detector. Such devices, methods and uses can be employed for example in various areas of daily life, gaming, traffic technology, production technology, security technology, medical technology or in the sciences. Additionally or alternatively, the application may be applied in the field of mapping of spaces, such as for generating maps of one or more rooms, one or more buildings or one or more streets. However,
15 other applications are also possible in principle.

Prior art

A large number of optical sensors and photovoltaic devices are known from the prior art. While
20 photovoltaic devices are generally used to convert electromagnetic radiation, for example, ultraviolet, visible or infrared light, into electrical signals or electrical energy, optical detectors are generally used for picking up image information and/or for detecting at least one optical parameter, for example, a brightness.

25 A large number of optical sensors which can be based generally on the use of inorganic and/or organic sensor materials are known from the prior art. Examples of such sensors are disclosed in US 2007/0176165 A1, US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1 or else in numerous other prior art documents. To an increasing extent, in particular for cost reasons and for reasons of large-area processing, sensors comprising at least one organic sensor material
30 are being used, as described for example in US 2007/0176165 A1. In particular, so-called dye solar cells are increasingly of importance here, which are described generally, for example in WO 2009/013282 A1.

35 As a further example, WO 2013/144177 A1 discloses quinolinium dyes having a fluorinated counter anion, an electrode layer which comprises a porous film made of oxide semiconductor fine particles sensitized with these kinds of quinolinium dyes having a fluorinated counter anion, a photoelectric conversion device which comprises such a kind of electrode layer, and a dye sensitized solar cell which comprises such a photoelectric conversion device.

40 A large number of detectors for detecting at least one object are known on the basis of such optical sensors. Such detectors can be embodied in diverse ways, depending on the respective purpose of use. Examples of such detectors are imaging devices, for example, cameras and/or

microscopes. High-resolution confocal microscopes are known, for example, which can be used in particular in the field of medical technology and biology in order to examine biological samples with high optical resolution. Further examples of detectors for optically detecting at least one object are distance measuring devices based, for example, on propagation time methods of corresponding optical signals, for example laser pulses. Further examples of detectors for optically detecting objects are triangulation systems, by means of which distance measurements can likewise be carried out.

Proceeding from such known detectors and methods for optically detecting objects, it can be ascertained that in many cases a considerable technical outlay has to be implemented in order to carry out this object detection with sufficient precision.

By way of example, in microscopy a considerable outlay in respect of apparatus is required in order to obtain correct focusing of a light beam and/or in order to obtain depth information about the sample to be imaged.

Another example for recording depth detection are active sensors which usually function by emitting a signal and measuring reflections of the signal caused by the at least one object. The active sensors have found a wide dissemination, particularly in applications related to computer vision. M.R. Andersen, T. Jensen, P. Lisouski, A.K. Mortensen, M.K. Hansen, T. Gregersen, and P. Ahrendt, *Kinect Depth Sensor Evaluation for Computer Vision Applications*, Technical report ECE-TR-6, 2012, Dept. of Engineering, Aarhus University, Denmark, describe a depth sensor which projects an infrared (IR) point pattern onto at least one object and measures its reflection pattern by use of an IR camera. According to their study, the authors could observe that this depth sensor required a settling time of approximately 30 seconds from the time the device was powered until a reliable depth signal was acquired, in particular owing to a large amount of computing power being required for performing this kind of procedure. Equivalently, a similar settling time could be observed when the depth sensor was rotated and quickly pointed towards a different scene.

A further problem arises when more than one active sensor is employed for acquiring depth information, particularly for extending a measurement range. As soon as signals which originate from one or more different or identical active sensors overlap, the origin of the signals becomes unidentifiable, so that in the region where the signals overlap no depth information can be recorded. A similar problem arises when two or more active sensors point towards each other. Particularly, since the measurement volume of an optical sensor can be described as an approximate cone, a large measurement volume can only be covered by a number of active sensors which, however, results in overlapping volumes and, thus, uncovered regions.

Distance measurements, by contrast, are based in many cases on technically inadequate assumptions such as, for example, the assumption of a specific size of an object in an image evaluation. Other methods are based in turn on complex pulse sequences, such as, for

example, distance measurements by means of laser pulses. Yet other methods are based on the use of a plurality of detectors such as, for example, triangulation methods.

5 In WO 2005/106965 A1, a setup of an organic solar cell is disclosed. A photo current is generated in response to incident light. Further, a method for producing the organic solar cell is disclosed. Therein, reference is made to the fact that defects or traps may diminish the efficiency of the organic solar cell.

10 Various position detectors are known in the art. Thus, in JP 8-159714 A, a distance measurement device is disclosed. Therein, by using a detector and a shadow-forming element, a distance between an object and the detector is determined based on the fact that shadow formation of objects depends on the distance. In US 2008/0259310 A1, an optical position detector is disclosed. The position of a transmission system is determined by using a variety of known distances and measured angles. In US 2005/0184301 A1, a distance measurement
15 device is disclosed. The measurement device makes use of a plurality of light-emitting diodes having different wavelengths. In CN 101650173 A, a position detector is disclosed which is based on the use of geometric principles. Further, in JP 10-221064 A, a complex optical setup is disclosed which is similar to optical setups used in holography.

20 In US 4,767,211, a device and a method for optical measurement and imaging are disclosed. Therein, a ratio of reflected light traveling along an optical axis and reflected light traveling off-axis is determined by using different photo-detectors and a divider. By using this principal, depressions in a sample may be detected.

25 In US 4,647,193, a range of a target object is determined by using a detector having multiple components. The detector is placed away from a focal plane of a lens. The size of a light spot of light from the object varies with the range of the object and, thus, is dependent on the range of the object. By using different photo-detectors, the size of the light spot and, thus, the range of the object may be determined by comparing signals generated by the photo-detectors.

30 In US 6,995,445 and US 2007/0176165 A1, a position sensitive organic detector is disclosed. Therein, a resistive bottom electrode, is used which is electrically contacted by using at least two electrical contacts. By forming a current ratio of the currents from the electric contacts, a position of a light spot on the organic detector may be detected.

35 In US 2007/0080925 A1, a low power consumption display device is disclosed. Therein, photoactive layers are utilized which both respond to electrical energy to allow a display device to display information and which generate electrical energy in response to incident radiation. Display pixels of a single display device may be divided into displaying and generating pixels.
40 The displaying pixels may display information and the generating pixels may generate electrical energy. The generated electrical energy may be used to provide power to drive an image.

US provisional applications 61/739,173, filed on December 19, 2012, and 61/749,964, filed on January 8, 2013, the full content of which is herewith included by reference, disclose a method and a detector for determining a position of at least one object, by using at least one transversal optical sensor and at least one optical sensor. Specifically, the use of sensor stacks is disclosed, in order to determine a longitudinal position of the object with a high degree of accuracy and without ambiguity.

European patent application number EP 13171898.3, filed on June 13, 2013, the full content of which is herewith included by reference, discloses an optical detector comprising an optical sensor having a substrate and at least one photosensitive layer setup disposed thereon. The photosensitive layer setup has at least one first electrode at least one second electrode and at least one photovoltaic material sandwiched in between the first electrode and the second electrode. The photovoltaic material comprises at least one organic material. The first electrode comprises a plurality of first electrode stripes, and the second electrode comprises a plurality of second electrode stripes, wherein the first electrode stripes and the second electrode stripes intersect such that a matrix of pixels is formed at intersections of the first electrode stripes and the second electrode stripes. The optical detector further comprises at least one readout device, the readout device comprising a plurality of electrical measurement devices being connected to the second electrode stripes and a switching device for subsequently connecting the first electrode stripes to the electrical measurement devices.

European patent application number EP 13171900.7, also filed on June 13, 2013, the full content of which is herewith included by reference, discloses a detector device for determining an orientation of at least one object, comprising at least two beacon devices being adapted to be at least one of attached to the object, held by the object and integrated into the object, the beacon devices each being adapted to direct light beams towards a detector, and the beacon devices having predetermined coordinates in a coordinate system of the object. The detector device further comprises at least one detector adapted to detect the light beams traveling from the beacon devices towards the detector and at least one evaluation device, the evaluation device being adapted to determine longitudinal coordinates of each of the beacon devices in a coordinate system of the detector. The evaluation device is further adapted to determine an orientation of the object in the coordinate system of the detector by using the longitudinal coordinates of the beacon devices.

European patent application number EP 13171901.5, filed on June 13, 2013, the full content of which is herewith included by reference, discloses a detector for determining a position of at least one object. The detector comprises at least one optical sensor being adapted to detect a light beam traveling from the object towards the detector, the optical sensor having at least one matrix of pixels. The detector further comprises at least one evaluation device, the evaluation device being adapted to determine a number N of pixels of the optical sensor which are illuminated by the light beam. The evaluation device is further adapted to determine at least one

longitudinal coordinate of the object by using the number N of pixels which are illuminated by the light beam.

5 In WO 2012/110924 A1, on which the present invention is based and the content of which is herewith included by reference, a detector for optically detecting at least one object is proposed. The detector comprises at least one optical sensor. The optical sensor has at least one sensor region. The optical sensor is designed to generate at least one sensor signal in a manner dependent on an illumination of the sensor region. The sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination, in particular on a
10 beam cross section of the illumination on the sensor area. The detector furthermore has at least one evaluation device. The evaluation device is designed to generate at least one item of geometrical information from the sensor signal, in particular at least one item of geometrical information about the illumination and/or the object.

15 Despite the advantages implied by the above-mentioned devices and detectors specifically by the detector disclosed in WO 2012/110924 A1, there still is a need for a simple, cost-efficient and, still, reliable spatial detector. Thus, an improved spatial resolution of an object in conjunction with the possibility of tracking the object in space is desirable.

20 Problem addressed by the invention

Therefore, a problem addressed by the present invention is that of specifying devices and methods for optically detecting at least one object which at least substantially avoid the disadvantages of known devices and methods of this type. In particular, an improved detector
25 for determining the position of an object in space and, preferably, for reliably tracking the object in space is desirable.

Summary of the invention

30 This problem is solved by the invention with the features of the independent patent claims. Advantageous developments of the invention, which can be realized individually or in combination, are presented in the dependent claims and/or in the following specification and detailed embodiments.

35 As used herein, the expressions "have", "comprise" and "contain" as well as grammatical variations thereof are used in a non-exclusive way. Thus, the expression "A has B" as well as the expression "A comprises B" or "A contains B" may both refer to the fact that, besides B, A contains one or more further components and/or constituents, and to the case in which, besides B, no other components, constituents or elements are present in A.

40

In a first aspect of the present invention, a detector for determining a position of at least one object is disclosed.

The object generally may be an arbitrary object, chosen from a living object and a non-living object. Thus, as an example, the at least one object may comprise one or more articles and/or one or more parts of an article. Additionally or alternatively, the object may be or may comprise
5 one or more living beings and/or one or more parts thereof, such as one or more body parts of a human being, e.g. a user, and/or an animal.

As used herein, a position generally refers to an arbitrary item of information on a location and/or orientation of the object in space. For this purpose, as an example, one or more
10 coordinate systems may be used, and the position of the object may be determined by using one, two, three or more coordinates. As an example, one or more Cartesian coordinate systems and/or other types of coordinate systems may be used. In one example, the coordinate system may be a coordinate system of the detector in which the detector has a predetermined position and/or orientation. As will be outlined in further detail below, the detector may have an optical
15 axis, which may constitute a main direction of view of the detector. The optical axis may form an axis of the coordinate system, such as a z-axis. Further, one or more additional axes may be provided, preferably perpendicular to the z-axis.

Thus, as an example, the detector may constitute a coordinate system in which the optical axis
20 forms the z-axis and in which, additionally, an x-axis and a y-axis may be provided which are perpendicular to the z-axis and which are perpendicular to each other. As an example, the detector and/or a part of the detector may rest at a specific point in this coordinate system, such as at the origin of this coordinate system. In this coordinate system, a direction parallel or antiparallel to the z-axis may be regarded as a longitudinal direction, and a coordinate along the
25 z-axis may be considered a longitudinal coordinate. An arbitrary direction perpendicular to the longitudinal direction may be considered a transversal direction, and an x- and/or y-coordinate may be considered a transversal coordinate.

Alternatively, other types of coordinate systems may be used. Thus, as an example, a polar
30 coordinate system may be used in which the optical axis forms a z-axis and in which a distance from the z-axis and a polar angle may be used as additional coordinates. Again, a direction parallel or antiparallel to the z-axis may be considered a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. Any direction perpendicular to the z-axis may be considered a transversal direction, and the polar coordinate and/or the polar
35 angle may be considered a transversal coordinate.

As used herein, a detector for determining a position of at least one object generally is a device adapted for providing at least one item of information on the position of the at least one object. The detector may be a stationary device or a mobile device. Further, the detector may be a
40 stand-alone device or may form part of another device, such as a computer, a vehicle or any other device. Further, the detector may be a hand-held device. Other embodiments of the detector are feasible.

The detector may be adapted to provide the at least one item of information on the position of the at least one object in any feasible way. Thus, the information may e.g. be provided electronically, visually, acoustically or in any arbitrary combination thereof. The information may
5 further be stored in a data storage of the detector or a separate device and/or may be provided via at least one interface, such as a wireless interface and/or a wire-bound interface.

The detector comprises:

- at least one transversal optical sensor, the transversal optical sensor being adapted to
10 determine a transversal position of at least one light beam traveling from the object to the detector, the transversal position being a position in at least one dimension perpendicular an optical axis of the detector, the transversal optical sensor being adapted to generate at least one transversal sensor signal;
- at least one longitudinal optical sensor, wherein the longitudinal optical sensor has at
15 least one sensor region, wherein the longitudinal optical sensor is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region by the light beam, wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam in the sensor region;
- at least one evaluation device, wherein the evaluation device is designed to generate at
20 least one item of information on a transversal position of the object by evaluating the transversal sensor signal and to generate at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal.

As will be outlined in further detail below, the components listed above may be separate
25 components. Alternatively, two or more of the components listed above may be integrated into one component. Thus, the at least one transversal optical sensor and the at least one longitudinal optical sensor may at least partially be integrated into one optical sensor. Alternatively, at least one longitudinal optical sensor may be provided which is separate from at least one transversal optical sensor. Further, the at least one evaluation device may be formed
30 as a separate evaluation device independent from the at least one transversal optical sensor and the at least one longitudinal optical sensor, but may preferably be connected to the at least one transversal optical sensor and the at least one longitudinal optical sensor in order to receive the transversal sensor signal and the longitudinal sensor signal. Alternatively, the at least one evaluation device may fully or partially be integrated into the at least one transversal optical
35 sensor and/or the at least one longitudinal optical sensor.

As used herein, the term transversal optical sensor generally refers to a device which is adapted to determine a transversal position of at least one light beam traveling from the object to the detector. With regard to the term transversal position, reference may be made to the
40 definition given above. Thus, preferably, the transversal position may be or may comprise at least one coordinate in at least one dimension perpendicular to an optical axis of the detector. As an example, the transversal position may be a position of a light spot generated by the light

beam in a plane perpendicular to the optical axis, such as on a light-sensitive sensor surface of the transversal optical sensor. As an example, the position in the plane may be given in Cartesian coordinates and/or polar coordinates. Other embodiments are feasible.

- 5 For potential embodiments of the transversal optical sensor, reference may be made to the position sensitive organic detector as disclosed in US 6,995,445 and US 2007/0176165 A1. However, other embodiments are feasible and will be outlined in further detail below.

10 The at least one transversal sensor signal generally may be an arbitrary signal indicative of the transversal position. As an example, the transversal sensor signal may be or may comprise a digital and/or an analog signal. As an example, the transversal sensor signal may be or may comprise a voltage signal and/or a current signal. Additionally or alternatively, the transversal sensor signal may be or may comprise digital data. The transversal sensor signal may comprise a single signal value and/or a series of signal values. The transversal sensor signal may further
15 comprise an arbitrary signal which is derived by combining two or more individual signals, such as by averaging two or more signals and/or by forming a quotient of two or more signals, as will be outlined in further detail below.

As used herein, a longitudinal optical sensor generally is a device which is designed to generate
20 at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region by the light beam, wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam in the sensor region. For potential embodiments of the longitudinal optical sensor, reference may be made to the optical sensor as disclosed in WO 2012/110924 A1. Preferably, however, as will be outlined in
25 further detail below, the detector according to the present invention comprises a plurality of optical sensors, such as a plurality of optical sensors as disclosed in WO 2012/110924 A1, preferably as a sensor stack.

Thus, as an example, the detector according to the present invention may comprise a stack of
30 optical sensors as disclosed in WO 2012/110924 A1, in combination with one or more transversal optical sensors. As an example, one or more transversal optical sensors may be disposed on a side of the stack of longitudinal optical sensors facing towards the object. Alternatively or additionally, one or more transversal optical sensors may be disposed on a side of the stack of longitudinal optical sensors facing away from the object. Again, additionally or
35 alternatively, one or more transversal article sensors may be interposed in between the longitudinal optical sensors of the stack.

As will further be outlined below, preferably, both the at least one transversal optical sensor longitudinal optical sensor and the at least one longitudinal optical sensor may comprise one or
40 more photo detectors, preferably one or more organic photodetectors and, most preferably, one or more dye-sensitized organic solar cells (DSCs, also referred to as dye solar cells), such as one or more solid dye-sensitized organic solar cells (s-DSCs). Thus, preferably, the detector

may comprise one or more DSCs (such as one or more sDSCs) acting as the at least one transversal optical sensor and one or more DSCs (such as one or more sDSCs) acting as the at least one longitudinal optical sensor, preferably a stack of a plurality of DSCs (preferably a stack of a plurality of sDSCs) acting as the at least one longitudinal optical sensor.

5

As used herein, the term evaluation device generally refers to an arbitrary device designed to generate the at least one item of information on the transversal position of the object and the longitudinal position of the object. As an example, the evaluation device may be or may comprise one or more integrated circuits, such as one or more application-specific integrated circuits (ASICs), and/or one or more data processing devices, such as one or more computers, preferably one or more microcomputers and/or microcontrollers. Additional components may be comprised, such as one or more preprocessing devices and/or data acquisition devices, such as one or more devices for receiving and/or preprocessing of the transversal sensor signal and/or the longitudinal sensor signal, such as one or more AD-converters and/or one or more filters. Further, the evaluation device may comprise one or more data storage devices. Further, as outlined above, the evaluation device may comprise one or more interfaces, such as one or more wireless interfaces and/or one or more wire-bound interfaces.

10

15

20

25

The at least one evaluation device may be adapted to perform at least one computer program, such as at least one computer program performing or supporting the step of generating the at least one item of information on the transversal position and/or the step of generating the at least one item of information on the longitudinal position. As an example, one or more algorithms may be implemented which, by using the transversal sensor signal and/or the longitudinal sensor signal as input variables, may perform a predetermined transformation into the transversal position and/or the longitudinal position of the object.

30

As outlined above, preferably, the transversal optical sensor is a photo detector having at least one first electrode, at least one second electrode and at least one photovoltaic material, wherein the photovoltaic material is embedded in between the first electrode and the second electrode. As used herein, a photovoltaic material generally is a material or combination of materials adapted to generate electric charges in response to an illumination of the photovoltaic material with light.

35

40

As used herein, the term light generally refers to electromagnetic radiation in one or more of the visible spectral range, the ultraviolet spectral range and the infrared spectral range. Therein, the term visible spectral range generally refers to a spectral range of 380 nm to 780 nm. The term infrared (IR) spectral range generally refers to electromagnetic radiation in the range of 780 nm to 1000 μm , preferably in the range of 780 nm to 3.0 μm . The term ultraviolet spectral range generally refers to electromagnetic radiation in the range of 1 nm to 380 nm, preferably in the range of 100 nm to 380 nm. Preferably, light as used within the present invention is visible light, i.e. light in the visible spectral range.

The term light beam generally refers to an amount of light emitted into a specific direction. Thus, the light beam may be a bundle of the light rays having a predetermined extension in a direction perpendicular to a direction of propagation of the light beam. Preferably, the light beam may be or may comprise one or more Gaussian light beams which may be characterized by one or more Gaussian beam parameters, such as one or more of a beam waist, a Rayleigh-length or any other beam parameter or combination of beam parameters suited to characterize a development of a beam diameter and/or a beam propagation in space.

Preferably, the second electrode of the transversal optical sensor may be a split electrode having at least two partial electrodes, wherein the transversal optical sensor has a sensor area, wherein the at least one transversal sensor signal indicates a position of the light beam in the sensor area. Thus, as outlined above, the transversal optical sensor may be or may comprise one or more photo detectors, preferably one or more organic photo detectors, more preferably one or more DSCs or sDSCs. The sensor area may be a surface of the photo detector facing towards the object. The sensor area preferably may be oriented perpendicular to the optical axis. Thus, the transversal sensor signal may indicate a position of a light spot generated by the light beam in a plane of the sensor area of the transversal optical sensor.

Generally, as used herein, the term partial electrode refers to an electrode out of a plurality of electrodes, adapted for measuring at least one current and/or voltage signal, preferably independent from other partial electrodes. Thus, in case a plurality of partial electrodes is provided, the second electrode is adapted to provide a plurality of electric potentials and/or electric currents and/or voltages via the at least two partial electrodes, which may be measured and/or used independently.

When using at least one transversal optical sensor having at least one split electrode having two or more partial electrodes as a second electrode, currents through the partial electrodes may be dependent on a position of the light beam in the sensor area. This may generally be due to the fact that Ohmic losses or resistive losses may occur on the way from a location of generation of electrical charges due to the impinging light to the partial electrodes. Thus, besides the partial electrodes, the second electrode may comprise one or more additional electrode materials connected to the partial electrodes, wherein the one or more additional electrode materials provide an electrical resistance. Thus, due to the Ohmic losses on the way from the location of generation of the electric charges to the partial electrodes through with the one or more additional electrode materials, the currents through the partial electrodes depend on the location of the generation of the electric charges and, thus, to the position of the light beam in the sensor area. For details of this principle of determining the position of the light beam in the sensor area, reference may be made to the preferred embodiments below and/or to the physical principles and device options as disclosed e.g. in US 6,995,445 and/or US 2007/0176165 A1.

The transversal optical sensor may further be adapted to generate the transversal sensor signal in accordance with the electrical currents through the partial electrodes. Thus, a ratio of electric currents through two horizontal partial electrodes may be formed, thereby generating an x-coordinate, and/or a ratio of electric currents through two vertical partial electrodes may be formed, thereby generating a y-coordinate. The detector, preferably the transversal optical sensor and/or the evaluation device, may be adapted to derive the information on the transversal position of the object from at least one ratio of the currents through the partial electrodes. Other ways of generating position coordinates by comparing currents through the partial electrodes are feasible.

The partial electrodes generally may be defined in various ways, in order to determine a position of the light beam in the sensor area. Thus, two or more horizontal partial electrodes may be provided in order to determine a horizontal coordinate or x-coordinate, and two or more vertical partial electrodes may be provided in order to determine a vertical coordinate or y-coordinate. Thus, the partial electrodes may be provided at a rim of the sensor area, wherein an interior space of the sensor area remains free and may be covered by one or more additional electrode materials. As will be outlined in further detail below, the additional electrode material preferably may be a transparent additional electrode material, such as a transparent metal and/or a transparent conductive oxide and/or, most preferably, a transparent conductive polymer.

Further preferred embodiments may refer to the photovoltaic material. Thus, the photovoltaic material of the transversal optical sensor may comprise at least one organic photovoltaic material. Thus, generally, the transversal optical sensor may be an organic photo detector. Preferably, the organic photo detector may be a dye-sensitized solar cell. The dye-sensitized solar cell preferably may be a solid dye-sensitized solar cell, comprising a layer setup embedded in between the first electrode and the second electrode, the layer setup comprising at least one n-semiconducting metal oxide, at least one dye, and at least one solid p-semiconducting organic material. Further details and optional embodiments of the dye-sensitized solar cell (DSC) will be disclosed below.

The at least one first electrode of the transversal optical sensor preferably is transparent. As used in the present invention, the term transparent generally refers to the fact that the intensity of light after transmission through the transparent object equals to or exceeds 10%, preferably 40% and, more preferably, 60% of the intensity of light before transmission through the transparent object. More preferably, the at least one first electrode of the transversal optical sensor may fully or partially be made of at least one transparent conductive oxide (TCO). As an example, indium-doped tin oxide (ITO) and/or fluorine-doped tin oxide (FTO) may be named. Further examples will be given below.

Further, the at least one second electrode of the transversal optical sensor preferably may fully or partially be transparent. Thus, specifically, the at least one second electrode may comprise

two or more partial electrodes and at least one additional electrode material contacting the two or more partial electrodes. The two or more partial electrodes may be intransparent. As an example, the two or more partial electrodes may fully or partially be made of a metal. Thus, the two or more partial electrodes preferably are located at a rim of the sensor area. The two or more partial electrodes, however, may electrically be connected by the at least one additional electrode material which, preferably, is transparent. Thus, the second electrode may comprise an intransparent rim having the two or more partial electrodes and a transparent inner area having the at least one transparent additional electrode material. More preferably, the at least one second electrode of the transversal optical sensor, such as the above-mentioned at least one additional electrode material, may fully or partially be made of at least one conductive polymer, preferably a transparent conductive polymer. As an example, conductive polymers having an electrical conductivity of at least 0.01 S/cm may be used, preferably of at least 0.1 S/cm or, more preferably, of at least 1 S/cm or even at least 10 S/cm or at least 100 S/cm. As an example, the at least one conductive polymer may be selected from the group consisting of: a poly-3,4-ethylenedioxythiophene (PEDOT), preferably PEDOT being electrically doped with at least one counter ion, more preferably PEDOT doped with sodium polystyrene sulfonate (PEDOT:PSS); a polyaniline (PANI); a polythiophene.

As outlined above, the conductive polymer may provide an electrical connection between the at least two partial electrodes. The conductive polymer may provide an Ohmic resistivity, allowing for determining the position of charge generation. Preferably, the conductive polymer provides an electric resistivity of 0.1 – 20 k Ω between the partial electrodes, preferably an electric resistivity of 0.5 – 5.0 k Ω and, more preferably, an electric resistivity of 1.0 – 3.0 k Ω .

Generally, as used herein, a conductive material may be a material which have a specific electrical resistance of less than 10^4 , less than 10^3 , less than 10^2 , or of less than 10 Ω m. Preferably, the conductive material has a specific electrical resistance of less than 10^{-1} , less than 10^{-2} , less than 10^{-3} , less than 10^{-5} , or less than 10^{-6} Ω m. Most preferably, the specific electrical resistance of the conductive material is less than 5×10^{-7} Ω m or is less than 1×10^{-7} Ω m, particularly in the range of the specific electrical resistance of aluminum.

As outlined above, preferably, at least one of the transversal optical sensor and the longitudinal optical sensor is a transparent optical sensor. Thus, the at least one transversal optical sensor may be a transparent transversal optical sensor and/or may comprise at least one transparent transversal optical sensor. Additionally or alternatively, the at least one longitudinal optical sensor may be a transparent longitudinal optical sensor and/or may comprise at least one transparent longitudinal optical sensor. In case a plurality of longitudinal optical sensors is provided, such as a stack of longitudinal optical sensors, preferably all longitudinal optical sensors of the plurality and/or the stack or all longitudinal optical sensors of the plurality and/or the stack but one longitudinal optical sensor are transparent. As an example, in case a stack of longitudinal optical sensors is provided, wherein the longitudinal optical sensors are arranged along the optical axis of the detector, preferably all longitudinal optical sensors but the last

longitudinal optical sensor facing away from the object may be transparent longitudinal optical sensors. The last longitudinal optical sensor, i.e. the longitudinal optical sensor on the side of the stack facing away from the object, may be a transparent longitudinal optical sensor or an intransparent longitudinal optical sensor. Exemplary embodiments will be given below.

5

In case one of the transversal optical sensor and the longitudinal optical sensor is a transparent optical sensor or comprises at least one transparent optical sensor, the light beam may pass through the transparent optical sensor before impinging on the other one of the transversal optical sensor and the longitudinal optical sensor. Thus, the light beam from the object may subsequently reach the transversal optical sensor and the longitudinal optical sensor or vice versa.

10

Further embodiments refer to the relationship between the transversal optical sensor and the longitudinal optical sensor. Thus, in principle, the transversal optical sensor and the longitudinal optical sensor at least partially may be identical, as outlined above. Preferably, however, the transversal optical sensor and the longitudinal optical sensor at least partially may be independent optical sensors, such as independent photo detectors and, more preferably, independent DSCs or sDSCs.

15

As outlined above, the transversal optical sensor and the longitudinal optical sensor preferably may be stacked along the optical axis. Thus, a light beam travelling along the optical axis may both impinge on the transversal optical sensor and on the longitudinal optical sensor, preferably subsequently. Thus, the light beam may subsequently pass through the transversal optical sensor and the longitudinal optical sensor or vice versa.

20

Further embodiments of the present invention referred to the nature of the light beam which propagates from the object to the detector. The light beam might be admitted by the object itself, i.e. might originate from the object. Additionally or alternatively, another origin of the light beam is feasible. Thus, as will be outlined in further detail below, one or more illumination sources might be provided which illuminate the object, such as by using one or more primary rays or beams, such as one or more primary rays or beams having a predetermined characteristic. In the latter case, the light beam propagating from the object to the detector might be a light beam which is reflected by the object and/or a reflection device connected to the object.

25

As outlined above, the at least one longitudinal sensor signal, given the same total power of the illumination by the light beam, is dependent on a beam cross-section of the light beam in the sensor region of the at least one longitudinal optical sensor. As used herein, the term beam cross-section generally refers to a lateral extension of the light beam or a light spot generated by the light beam at a specific location. In case a circular light spot is generated, a radius, a diameter or a Gaussian beam waist or twice the Gaussian beam waist may function as a measure of the beam cross-section. In case non-circular light-spots are generated, the cross-

30

35

40

section may be determined in any other feasible way, such as by determining the cross-section of a circle having the same area as the non-circular light spot, which is also referred to as the equivalent beam cross-section.

5 Thus, given the same total power of the illumination of the sensor region by the light beam, a light beam having a first beam diameter or beam cross-section may generate a first longitudinal sensor signal, whereas a light beam having a second beam diameter or beam-cross section being different from the first beam diameter or beam cross-section generates a second longitudinal sensor signal being different from the first longitudinal sensor signal. Thus, by
10 comparing the longitudinal sensor signals, an information or at least one item of information on the beam cross-section, specifically on the beam diameter, may be generated. For details of this effect, reference may be made to WO 2012/110924 A1. Specifically in case one or more beam properties of the light beam propagating from the object to the detector are known, the at least one item of information on the longitudinal position of the object may thus be derived from
15 a known relationship between the at least one longitudinal sensor signal and a longitudinal position of the object. The known relationship may be stored in the evaluation device as an algorithm and/or as one or more calibration curves. As an example, specifically for Gaussian beams, a relationship between a beam diameter or beam waist and a position of the object may easily be derived by using the Gaussian relationship between the beam waist and a longitudinal
20 coordinate.

The above-mentioned effect, which is also referred to as the FiP-effect (alluding to the effect that the beam cross section ϕ influences the electric power P generated by the longitudinal optical sensor) may depend on or may be emphasized by an appropriate modulation of the light
25 beam, as disclosed in WO 2012/110924 A1. Thus, preferably, the detector may furthermore have at least one modulation device for modulating the illumination. The detector may be designed to detect at least two longitudinal sensor signals in the case of different modulations, in particular at least two sensor signals at respectively different modulation frequencies. In this case, the evaluation device may be designed to generate the at least one item of information on
30 the longitudinal position of the object by evaluating the at least two longitudinal sensor signals.

Generally, the longitudinal optical sensor may be designed in such a way that the at least one longitudinal sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination. Further details and exemplary
35 embodiments will be given below. This property of frequency dependency is specifically provided in DSCs and, more preferably, in sDSCs. However, other types of optical sensors, preferably photo detectors and, more preferably, organic photo detectors may exhibit this effect.

Preferably, the transversal optical sensor and the longitudinal optical sensor both are thin film
40 devices, having a layer setup of layer including electrode and photovoltaic material, the layer setup having a thickness of preferably no more than 1 mm, more preferably of at most 500 μm or even less. Thus, the sensor region of the transversal optical sensor and/or the sensor region

of the longitudinal optical sensor preferably each may be or may comprise a sensor area, which may be formed by a surface of the respective device, wherein the surface may face towards the object or may face away from the object. Hereby, it may further be feasible to arrange the at least one transversal optical sensor and the at least one longitudinal optical sensor in a way that some surfaces comprising the sensor regions may face towards the object where other surfaces may face away from the object. Such a kind of arrangement of the respective devices, which might be helpful to optimize the path of the light beam through the stack and/or to reduce reflections within the light path, may, for any reason or purpose, be implemented in an alternating manner, such as with one, two, three or more devices where the sensor regions may face towards the object alternating with one, two, three or more other devices where the sensor regions may face away from the object.

Preferably, the sensor region of the transversal optical sensor and/or the sensor region of the longitudinal optical sensor may be formed by one continuous sensor region, such as one continuous sensor area or sensor surface per device. Thus, preferably, the sensor region of the longitudinal optical sensor or, in case a plurality of longitudinal optical sensors is provided (such as a stack of longitudinal optical sensors), each sensor region of the longitudinal optical sensor, may be formed by exactly one continuous sensor region. The longitudinal sensor signal preferably is a uniform sensor signal for the entire sensor region of the longitudinal optical sensor or, in case a plurality of longitudinal optical sensors is provided, is a uniform sensor signal for each sensor region of each longitudinal optical sensor.

The at least one transversal optical sensor and/or the at least one longitudinal optical sensor each, independently, may have a sensor region providing a sensitive area, also referred to as a sensor area, of at least 1 mm², preferably of at least 5 mm², such as a sensor area of 5 mm² to 1000 cm², preferably a sensor area of 7 mm² to 100 cm², more preferably a sensor area of 1 cm². The sensor area preferably has a rectangular geometry, such as a square geometry. However, other geometries and/or sensor areas are feasible.

The longitudinal sensor signal preferably may be selected from the group consisting of a current (such as a photocurrent) and a voltage (such as a photo voltage). Similarly, the transversal sensor signal preferably may be selected from the group consisting of a current (such as a photocurrent) and a voltage (such as a photo voltage) or any signal derived thereof, such as a quotient of currents and/or voltages. Further, longitudinal sensor signal and/or the transversal sensor signal may be preprocessed, in order to derive refined sensor signals from raw sensor signals, such as by averaging and/or filtering.

Generally, the longitudinal optical sensor may comprise at least one semiconductor detector, in particular an organic semiconductor detector comprising at least one organic material, preferably an organic solar cell and particularly preferably a dye solar cell or dye-sensitized solar cell, in particular a solid dye solar cell or a solid dye-sensitized solar cell. Preferably, the longitudinal optical sensor is or comprises a DSC or sDSC. Thus, preferably, the longitudinal

optical sensor comprises at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid p-semiconducting organic material, and at least one second electrode. In a preferred embodiment, the longitudinal optical sensor comprises at least one DSC or, more preferably, at least one sDSC. As outlined above, preferably, the at least one longitudinal optical sensor is a transparent longitudinal optical sensor or comprises at least one transparent longitudinal optical sensor. Thus, preferably, both the first electrode and the second electrode are transparent or, in case a plurality of longitudinal optical sensors is provided, at least one of the longitudinal optical sensors is designed such that both the first electrode and the second electrode are transparent.

As outlined above, in case a stack of longitudinal optical sensors is provided, preferably some or even all longitudinal optical sensors of the stack are transparent but the last longitudinal optical sensor of the stack. The last longitudinal optical sensor of the stack, i.e. the longitudinal optical sensor of the stack furthest away from the object, may be transparent or intransparent.

The stack may, besides the at least one transversal optical sensor and the at least one longitudinal optical sensor, comprise one or more further optical sensors which may function as one or more of a transversal optical sensor, a longitudinal optical sensor (also referred to as an imaging device) and an imaging sensor.

Thus, it may be possible to locate an imaging device in the optical path of the light beam in a manner that the light beam travels through the stack of the transparent longitudinal optical sensors until it impinges on the imaging device.

Thus, generally, the detector may further comprise at least one imaging device, i.e. a device capable of acquiring at least one image. The imaging device can be embodied in various ways. Thus, the imaging device can be for example part of the detector in a detector housing. Alternatively or additionally, however, the imaging device can also be arranged outside the detector housing, for example as a separate imaging device. Alternatively or additionally, the imaging device can also be connected to the detector or even be part of the detector. In a preferred arrangement, the stack of the transparent longitudinal optical sensors and the imaging device are aligned along a common optical axis along which the light beam travels. However, other arrangements are possible.

In addition, the detector may comprise at least one transfer device, such as an optical lens, which will be described later in more detail, and which may further be arranged along the common optical axis. By way of example, the light beam which emerges from the object may in this case travel first through the at least one transfer device and thereafter through the stack of the transparent longitudinal optical sensors until it finally impinges on the imaging device.

As used herein, an imaging device is generally understood as a device which can generate a one-dimensional, a two-dimensional, or a three-dimensional image of the object or of a part thereof. In particular, the detector, with or without the at least one optional imaging device, can

be completely or partly used as a camera, such as an IR camera, or an RGB camera, i.e. a camera which is designed to deliver three basic colors which are designated as red, green, and blue, on three separate connections. Thus, as an example, the at least one imaging device may be or may comprise at least one imaging device selected from the group consisting of: a
5 pixelated organic camera element, preferably a pixelated organic camera chip; a pixelated inorganic camera element, preferably a pixelated inorganic camera chip, more preferably a CCD- or CMOS-chip; a monochrome camera element, preferably a monochrome camera chip; a multicolor camera element, preferably a multicolor camera chip; a full-color camera element, preferably a full-color camera chip. The imaging device may be or may comprise at least one
10 device selected from the group consisting of a monochrome imaging device, a multi-chrome imaging device and at least one full color imaging device. A multi-chrome imaging device and/or a full color imaging device may be generated by using filter techniques and/or by using intrinsic color sensitivity or other techniques, as the skilled person will recognize. Other embodiments of the imaging device are also possible.

15 The imaging device may be designed to image a plurality of partial regions of the object successively and/or simultaneously. By way of example, a partial region of the object can be a one-dimensional, a two-dimensional, or a three-dimensional region of the object which is delimited for example by a resolution limit of the imaging device and from which electromagnetic
20 radiation emerges. In this context, imaging should be understood to mean that the electromagnetic radiation which emerges from the respective partial region of the object is fed into the imaging device, for example by means of the at least one optional transfer device of the detector. The electromagnetic rays can be generated by the object itself, for example in the form of a luminescent radiation. Alternatively or additionally, the at least one detector may
25 comprise at least one illumination source for illuminating the object.

In particular, the imaging device can be designed to image sequentially, for example by means of a scanning method, in particular using at least one row scan and/or line scan, the plurality of partial regions sequentially. However, other embodiments are also possible, for example
30 embodiments in which a plurality of partial regions is simultaneously imaged. The imaging device is designed to generate, during this imaging of the partial regions of the object, signals, preferably electronic signals, associated with the partial regions. The signal may be an analogue and/or a digital signal. By way of example, an electronic signal can be associated with each partial region. The electronic signals can accordingly be generated simultaneously or else
35 in a temporally staggered manner. By way of example, during a row scan or line scan, it is possible to generate a sequence of electronic signals which correspond to the partial regions of the object, which are strung together in a line, for example. Further, the imaging device may comprise one or more signal processing devices, such as one or more filters and/or analogue-digital-converters for processing and/or preprocessing the electronic signals.

40 As outlined above, the at least one longitudinal optical sensor may be transparent or intransparent, or may comprise at least one transparent longitudinal optical sensor. A

combination of at least one transparent and at least one intransparent longitudinal optical sensor is possible.

5 In a further preferred embodiment, the last longitudinal optical sensor may be intransparent. For this purpose, at least those parts of the last longitudinal optical sensor which are subject to be illuminated by the light beam which travels from the object and which may impinge on the last longitudinal optical sensor may comprise an optical sensor material, preferably an inorganic optical sensor material, and/or an organic optical sensor material, and/or a hybrid organic – inorganic optical sensor material, which exhibits intransparent optical properties. Intransparency
10 may also be achieved by using at least one intransparent electrode. In this embodiment, the last longitudinal optical sensor may be designed such that its electrode facing towards the object is transparent, whereas its electrode facing away from the object may be intransparent, or vice-versa. Additionally or alternatively, a respective material which exhibits intransparent optical properties may be selected for at least one of the n-semiconducting metal oxides, for at least
15 one of the dyes, and/or for at least one of the p-semiconducting organic materials which may comprise the last longitudinal optical sensor.

As outlined above, the detector may comprise at least one imaging device. The imaging device may fully or partially be embodied as an independent imaging device, independent from the at
20 least one transversal optical sensor and the at least one longitudinal optical sensor. Additionally or alternatively, the at least one optional imaging device may fully or partially be integrated into one or both of the at least one transversal optical sensor and the at least one longitudinal optical sensor. Thus, as an example, the imaging device may be used for determining a transversal position of a light spot and, thus, may be used as a transversal optical sensor or as a part
25 thereof.

As outlined above, the detector may comprise a stack of at least two optical sensors, the at least two optical sensors comprising the at least one transversal optical sensor and the at least one longitudinal optical sensor and, optionally, the at least one imaging device. Thus, as an
30 example, the stack may comprise the at least one transversal optical sensor, the at least one longitudinal optical sensor (preferably at least one transparent longitudinal optical sensor) and, optionally, in a position furthest away from the object, at least one imaging device, preferably at least one intransparent imaging device such as a CCD or CMOS chip.

35 The stack of at least two optical sensors optionally may partially or fully be immersed in an oil, in a liquid and/or in a solid material in order to avoid and/or decrease reflections at interfaces. Hereby, the oil, the liquid, and/or the solid material may preferably be transparent, preferentially to a high degree, at least over a part of the ultraviolet, visible, and/or infrared spectral range. In a preferred embodiment, the solid material may be generated by inserting at least one curable
40 substance into a region between at least two optical sensors and treating the curable substance with a treatment, such as by incident light, particularly with light within the ultraviolet range, and/or by an application of a temperature above or below room temperature, by which treatment

the curable substance might be cured, preferentially by hardening the curable substance into the solid material. Alternatively, at least two different curable substances may be inserted into a region between at least two optical sensors, whereby the two different curable substances are selected in a manner that they begin to set into the solid material with or without the treatment as indicated above. However, further treatments and/or other procedures of providing the transparent solid material may be possible. Thus, at least one of the optical sensors of the stack may fully or partially be immersed in the oil and/or the liquid and/or covered with the solid material.

Alternatively or additionally, the region between the at least two optical sensors may be partially or fully filled with a substance, such as the oil, the liquid and/or the solid material. Hereby, the substance may preferably exhibit a refractive index with a value which may differ from that of the optical sensors adjoining to the substance on one or both sides of the region. However, inserting the additional substance in the regions may require the optical sensors within the stack to observe a minimum spacing between them.

In case a stack of at least two optical sensors is used, the last optical sensor of the stack may be transparent or intransparent. Thus, an intransparent inorganic optical sensor may be used in a position furthest away from the object. As an example, the last optical sensor of the stack may be or may comprise the at least one optional imaging device, such as at least one CCD or CMOS chip, preferably a full-color CCD or CMOS chip.

Thus, the intransparent last optical sensor may be used as an imaging device, wherein the imaging device is impinged by the light beam after the light beam has traveled before through the stack of the transparent optical sensors until it impinges the imaging device. In particular, the imaging device can be completely or partly used as a camera, such as an IR camera, or an RGB camera, as described above. Hereby, the intransparent last optical sensor can be embodied in various ways as imaging device. Thus, the intransparent last optical sensor can be for example part of the detector in a detector housing. Alternatively or additionally, however, the intransparent last optical sensor can also be arranged outside the detector housing, for example as a separate imaging device.

The stack comprising the at least one transversal optical sensor, the at least one longitudinal optical sensor and the optional at least one imaging device may be designed such that the elements of the stack are arranged along an optical axis of the detector. The last element of the stack may be an intransparent optical sensor, preferably selected from the group consisting of an intransparent transversal optical sensor, an intransparent longitudinal optical sensor and an intransparent imaging device such as an intransparent CCD or CMOS chip.

In a preferred arrangement, the stack comprising the at least one transversal optical sensor, the at least one longitudinal optical sensor and, optionally, the at least one imaging device may be arranged along a common optical axis of the detector, along which the light beam may travel. In

case the stack contains a plurality of optical sensors, the optical sensors comprising the at least one transversal optical sensor, the at least one longitudinal optical sensor and, optionally, the at least one imaging device, wherein at least one of the optical sensors is a transparent optical sensor and wherein at least one of the optical sensors is an intransparent optical sensor, the transparent optical sensor and the intransparent optical sensor, the latter preferably being positioned furthest away from the object, may be arranged along the optical axis of the detector. However, other arrangements are possible.

In a further preferred embodiment, the intransparent last optical sensor is having at least one matrix of pixels, wherein a 'matrix' generally refers to an arrangement of a plurality of the pixels in space, which may be a linear arrangement or an areal arrangement. Generally, the matrix may, thus, preferably be selected from the group consisting of a one-dimensional matrix and a two-dimensional matrix. As an example, the matrix may comprise 100 to 100 000 000 pixels, preferably 1 000 to 1 000 000 pixels and, more preferably, 10 000 to 500 000 pixels. Most preferably, the matrix is a rectangular matrix having pixels arranged in rows and columns.

As further used herein, a pixel generally refers to a light-sensitive element of an optical sensor, such as a minimum uniform unit of the optical sensor adapted to generate a light signal. As an example, each pixel may have a light-sensitive area of $1\ \mu\text{m}^2$ to $5\,000\,000\ \mu\text{m}^2$, preferably $100\ \mu\text{m}^2$ to $4\,000\,000\ \mu\text{m}^2$, preferably $1\,000\ \mu\text{m}^2$ to $1\,000\,000\ \mu\text{m}^2$ and more preferably $2\,500\ \mu\text{m}^2$ to $50\,000\ \mu\text{m}^2$. Still, other embodiments are feasible. The intransparent last optical sensor may be adapted to generate at least one signal which indicates an intensity of illumination for each of the pixels. Thus, as an example, the intransparent last optical sensor may be adapted to generate at least one electronic signal for each of the pixels, whereby each signal indicates the intensity of illumination for the respective pixel. The signal may be an analogue and/or a digital signal. Further, the detector may comprise one or more signal processing devices, such as one or more filters and/or analogue-digital-converters for processing and/or preprocessing the at least one signal.

The intransparent last optical sensor having a matrix of pixels can be selected from the group consisting of: an inorganic semiconductor sensor device such as a CCD chip and/or a CMOS chip; an organic semiconductor sensor device. In the latter case, as an example, the optical sensor may, for example, comprise at least one organic photovoltaic device having a matrix of pixels. As used herein, an organic photovoltaic device generally refers to a device having at least one organic photosensitive element and/or at least one organic layer. Therein, generally, any type of organic photovoltaic device may be used, such as organic solar cells and/or an arbitrary device having at least one organic photosensitive layer. As an example, an organic solar cell and/or a dye-sensitized organic solar cell may be comprised. Further, a hybrid device may be used, such as inorganic – organic photovoltaic devices.

Further preferred embodiments refer to the evaluation device. Thus, the evaluation device may be designed to generate the at least one item of information on the longitudinal position of the

object from at least one predefined relationship between the geometry of the illumination and a relative positioning of the object with respect to the detector, preferably taking account of a known power of the illumination and optionally taking account of a modulation frequency with which the illumination is modulated.

5

In a further preferred embodiment, the detector furthermore may comprise at least one transfer device, wherein the transfer device is designed to feed light emerging from the object to the transversal optical sensor and the longitudinal optical sensor, preferably subsequently. Details and preferred embodiments will be given below.

10

As outlined above, the light beam propagating from the object of the detector may originate from the object or may originate from any other source. Thus, the object itself may emit the light beam. Additionally or alternatively, the object might be illuminated by using an illumination source generating primary light, wherein the object elastically or inelastically reflects the primary light, thereby generating the light beam propagating to the detector. The illumination source itself may be part of the detector. Thus, the detector may comprise at least one illumination source. The illumination source generally may be selected from: an illumination source, which is at least partly connected to the object and/or is at least partly identical to the object; an illumination source which is designed to at least partly illuminate the object with a primary radiation, preferably primary light, wherein the light beam preferably is generated by a reflection of the primary radiation on the object and/or by light emission by the object itself, stimulated by the primary radiation.

15

20

25

30

As outlined above, the detector preferably has a plurality of longitudinal optical sensors. More preferably, the plurality of longitudinal optical sensors is stacked, such as along the optical axis of the detector. Thus, the longitudinal optical sensors may form a longitudinal optical sensor stack. The longitudinal optical sensor stack preferably may be oriented such that the sensor regions of the longitudinal optical sensors are oriented perpendicular to the optical axis. Thus, as an example, sensor areas or sensor surfaces of the single longitudinal optical sensors may be oriented in parallel, wherein slight angular tolerances might be tolerable, such as angular tolerances of no more than 10°, preferably of no more than 5°.

35

In case stacked longitudinal optical sensors are provided, the at least one transversal optical sensor preferably fully or partially is located on a side of the stacked longitudinal optical sensors facing the object. However, other embodiments are feasible. Thus, embodiments in which the at least one transversal optical sensor is fully or partially located on a side of the transversal optical sensor stack facing away from the object. Again, additionally or alternatively, embodiments are feasible in which the at least one transversal optical sensor is located fully or partially in between the longitudinal optical sensor stack.

40

The longitudinal optical sensors preferably are arranged such that a light beam from the object illuminates all longitudinal optical sensors, preferably sequentially. Specifically in this case,

preferably, at least one longitudinal sensor signal is generated by each longitudinal optical sensor. This embodiment is specifically preferred since the stacked setup of the longitudinal optical sensors allows for an easy and efficient normalization of the signals, even if an overall power or intensity of the light beam is unknown. Thus, the single longitudinal sensor signals may be known to be generated by one and the same light beam. Thus, the evaluation device may be adapted to normalize the longitudinal sensor signals and to generate the information on the longitudinal position of the object independent from an intensity of the light beam. For this purpose, use may be made of the fact that, in case the single longitudinal sensor signals are generated by one and the same light beam, differences in the single longitudinal sensor signals are only due to differences in the cross-sections of the light beam at the location of the respective sensor regions of the single longitudinal optical sensors. Thus, by comparing the single longitudinal sensor signals, information on a beam cross-section may be generated even if the overall power of the light beam is unknown. From the beam cross-section, information regarding the longitudinal position of the object may be gained, specifically by making use of a known relationship between the cross-section of the light beam and the longitudinal position of the object.

Further, the above-mentioned stacking of the longitudinal optical sensors and the generation of a plurality of longitudinal sensor signals by these stacked longitudinal optical sensors may be used by the evaluation device in order to resolve an ambiguity in a known relationship between a beam cross-section of the light beam and the longitudinal position of the object. Thus, even if the beam properties of the light beam propagating from the object to the detector are known fully or partially, it is known that, in many beams, the beam cross-section narrows before reaching a focal point and, afterwards, widens again. Thus, before and often as a focal point in which the light beam has the narrowest beam cross-section, positions along the axis of propagation of the light beam occur in which the light beam has the same cross-section. Thus, as an example, at a distance z_0 before and after the focal point, the cross-section of the light beam is identical. Thus, in case only one longitudinal optical sensor is used, a specific cross-section of the light beam might be determined, in case the overall power or intensity of the light beam is known. By using this information, the distance z_0 of the respective longitudinal optical sensor from the focal point might be determined. However, in order to determine whether the respective longitudinal optical sensor is located before or behind the focal point, additional information is required, such as a history of movement of the object and/or the detector and/or information on whether the detector is located before or behind the focal point. In typical situations, this additional information may not be provided. Therefore, by using a plurality of longitudinal optical sensors, additional information may be gained in order to resolve the above-mentioned ambiguity. Thus, in case the evaluation device, by evaluating the longitudinal sensor signals, recognizes that the beam cross-section of the light beam on a first longitudinal optical sensor is larger than the beam cross-section of the light beam on a second longitudinal optical sensor, wherein the second longitudinal optical sensor is located behind the first longitudinal optical sensor, the evaluation device may determine that the light beam is still narrowing and that the location of the first longitudinal optical sensor is situated before the focal point of the

light beam. Contrarily, in case the beam cross-section of the light beam on the first longitudinal optical sensor is smaller than the beam cross-section of the light beam on the second longitudinal optical sensor, the evaluation device may determine that the light beam is widening and that the location of the second longitudinal optical sensor is situated behind the focal point.

- 5 Thus, generally, the evaluation device may be adapted to recognize whether the light beam widens or narrows, by comparing the longitudinal sensor signals of different longitudinal sensors.

- 10 In addition to the at least one longitudinal coordinate of the object, at least one transversal coordinate of the object may be determined. Thus, generally, the evaluation device may further be adapted to determine at least one transversal coordinate of the object by determining a position of the light beam on the at least one transversal optical sensor, which may be a pixelated, a segmented or a large-area transversal optical sensor, as will be outlined in further detail below.

- 15 Thus, in case a pixelated transversal optical sensor is used and/or in case the at least one transversal optical sensor comprises at least one pixelated optical sensor having a matrix of pixels, the evaluation device may be adapted to determine a center of illumination of the at least one matrix by the light beam, wherein the at least one transversal coordinate of the object is determined by evaluating at least one coordinate of the center of illumination. Thus, the coordinate of the center of illumination may be a pixel coordinate of the center of illumination. As an example, the matrix may comprise rows and columns of pixels, wherein the row number of the light beam and/or the center of the light beam within the matrix may provide an x-coordinate, and wherein the column number of the light beam and/or the center of the light beam within the matrix may provide a y-coordinate.

- The detector, as outlined above, may comprise at least one stack of optical sensors, the optical sensors comprising the at least one transversal optical sensor and the at least one longitudinal optical sensor, and, optionally, the at least one imaging device. The stack of optical sensors may comprise at least one longitudinal optical sensor stack, being a stack of longitudinal optical sensors, having at least two longitudinal optical sensors in a stacked fashion. The longitudinal optical sensor stack preferably may comprise at least three longitudinal optical sensors, more preferably at least four longitudinal optical sensors, even more preferably at least five longitudinal optical sensors or even at least six longitudinal optical sensors. By tracking the longitudinal sensor signals of the longitudinal optical sensors, even a beam profile of the light beam might be evaluated.

- In case a plurality of the longitudinal optical sensors is used, wherein the plurality of the optical sensors may be arranged in the stacked fashion and/or in another arrangement, the longitudinal optical sensors may have identical spectral sensitivities or may provide different spectral sensitivities. Thus, as an example, at least two of the longitudinal optical sensors may have a differing spectral sensitivity. As used herein, the term spectral sensitivity generally refers to the

fact that the sensor signal of the optical sensor, for the same power of the light beam, may vary with the wavelength of the light beam. Thus, generally, at least two of the optical sensors may differ with regard to their spectral properties. This embodiment generally may be achieved by using different types of absorbing materials for the optical sensors, such as different types of dyes or other absorbing materials.

Preferably, the at least one transversal optical sensor uses at least one transparent substrate. Similarly; preferably, the at least one longitudinal optical sensor uses at least one transparent substrate. In case a plurality of longitudinal optical sensors is used, such as a stack of longitudinal optical sensors, preferably, at least one of these longitudinal optical sensors uses a transparent substrate. Herein, the substrates employed for the plurality of optical sensors may exhibit identical properties or may differ from each other, in particular, with regard to a geometrical quantity and/or a material quantity related to the substrates, such as the thickness, the shape, and/or the refractive index of each substrate. Thus, identical planar glass plates may be used for the plurality of optical sensors within the stack. On the other hand, different substrates may be employed for some optical sensors or for each optical sensor within a plurality of optical sensors, in particular, for a purpose of optimizing the light path within the stack, especially for guiding the light path along regions on the optical axis which might particularly be suited for exploiting the FIP-effect as described elsewhere in this application. Within this regard, the thickness of some substrates or of each substrate, which may be defined by the light path as traversed by the light beam travelling through the respective substrate, may thus be varied, in particular, for reducing or else increasing or even maximizing reflections of the light beam.

In addition or alternatively, the substrates employed for the plurality of optical sensors may differ by exhibiting a different shape which may be selected from the group comprising a planar, a planar-convex, a planar-concave, a biconvex, a biconcave or any other form which may be employed for optical purposes, such as lenses or prisms. Herein, the substrates may be rigid or else flexible. Suitable substrates are, as well as metal foils, in particular plastic sheets or films and especially glass sheets or glass films. Shape-changing materials, such as shape-changing polymers, constitute an example of materials which may preferentially be employed as flexible substrates. Furthermore, the substrate may be covered or coated, in particular, for the purpose of reducing and/or modifying reflections of the incident light beam. As an example, the substrate may be shaped in a manner that it might exhibit a mirror effect, such as that of a dichroic mirror, which might particularly be useful in a setup where a splitting of the optical axis behind the substrate may be required for any purpose.

Additionally or alternatively, differing spectral properties of the optical sensors may be generated by other means implemented into the optical sensors and/or into the detector, such as by using one or more wavelength-selective elements, such as one or more filters (such as color filters) in front of the optical sensors and/or by using one or more prisms and/or by using one or more dichroitic mirrors and/or by using one or more color conversion elements. Thus, in

case a plurality of longitudinal optical sensors is provided, at least one of the longitudinal optical sensors may comprise a wavelength-selective element such as a color filter, having a specific transmission or reflection characteristic, thereby generating differing spectral properties of the optical sensors. Further, the longitudinal optical sensors may all be organic optical sensors, may
5 all be inorganic optical sensors, may all be hybrid organic – inorganic optical sensors or may comprise an arbitrary combination of at least two optical sensors selected from the group consisting of organic optical sensors, inorganic optical sensors and hybrid organic – inorganic optical sensors.

10 In case the plurality of the longitudinal optical sensors is used, wherein at least two of the longitudinal optical sensors differ with regard to their respective spectral sensitivity, the evaluation device generally may be adapted to determine a color of the light beam by comparing sensor signals of the longitudinal optical sensors having the differing spectral
15 sensitivity. As used herein, the expression “determine a color” generally refers to the step of generating at least one item of spectral information about the light beam. The at least one item of spectral information may be selected from the group consisting of a wavelength, specifically a peak wavelength; color coordinates, such as CIE coordinates. As further used herein, a “color” of the light beam generally refers to a spectral composition of the light beam. Specifically, the color of the light beam may be given in any arbitrary color coordinate system and/or in spectral
20 units such as by giving a wavelength of a dominant peak of a spectrum of the light. Other embodiments are feasible. In case the light beam is a narrow-band light beam such as a laser light beam and/or a light beam generated by a semiconductor device such as a light-emitting diode, the peak wavelength of the light beam may be given to characterize the color of the light beam. The determination of the color of the light beam may be performed in various ways which
25 are generally known to the skilled person. Thus, the spectral sensitivities of the longitudinal optical sensors may span a coordinate system in color space, and the signals provided by the optical sensors may provide a coordinate in this color space, as known to the skilled person for example from the way of determining CIE coordinates. As an example, the detector may comprise two, three or more longitudinal optical sensors in a stack. Thereof, at least two,
30 preferably at least three, of the optical sensors may have differing spectral sensitivities, whereby three different longitudinal optical sensors with maximum absorption wavelengths in a spectral range between 600 nm and 780 nm (red), between 490 nm and 600 nm (green), and between 380 nm and 490 nm (blue) are generally preferred. Further, the evaluation device may be adapted to generate at least one item of color information for the light beam by evaluating the
35 signals of the longitudinal optical sensors having differing spectral sensitivities.

The evaluation device may be adapted to generate at least two color coordinates, preferably at least three color coordinates, wherein each of the color coordinates is determined by dividing a signal of one of the spectrally sensitive optical sensors by a normalization value. As an
40 example, the normalization value may contain a sum of the signals of all spectrally sensitive optical sensors. Additionally or alternatively, the normalization value may contain a detector signal of a white detector. The at least one item of color information may contain the color

coordinates. The at least one item of color information may, as an example, contain CIE coordinates.

Furthermore, in addition to the preferred at least two, more preferably at least three, spectrally sensitive longitudinal optical sensors, wherein at least two of the optical sensors differ with regard to their respective spectral sensitivity, particularly wherein the spectral sensitivities of the at least two longitudinal optical sensors may span a coordinate system in color space, the stack may comprise a last longitudinal optical sensor, wherein the last longitudinal optical sensor may be intransparent. An intransparency of the last longitudinal optical sensor may be achieved by selecting an optically intransparent material from the group consisting of: organic optical sensor materials, inorganic optical sensor materials and hybrid organic – inorganic optical sensor materials.

In a preferred embodiment, the intransparent last longitudinal optical sensor may be configured to exhibit an absorption spectrum which either does not vary at all or varies only to minor extent over the spectral range of the at least two different optical sensors. Whereas each of the at least two different optical sensors displays a specific spectral sensitivity which may, as described above, vary considerably over their spectral range allowing them to be sensitive to a specific color, the intransparent last longitudinal optical sensor may, thus, absorb substantially all colors over the spectral ranges of the at least two of the longitudinal optical sensors have a differing spectral sensitivity. By this property, the last longitudinal optical sensor may be described as a white detector, wherein the white detector may be adapted to absorb light in an absorption range covering the visible spectral range. This arrangement has the advantage that, irrespective of the specific color, each beam which propagates through the at least two different optical sensors until it impinges the intransparent last longitudinal optical sensor, will be recorded by at least two different optical sensors, i.e. by at least one of the at least two different optical sensors which is sensitive to the color as the first longitudinal optical sensor and by the intransparent last longitudinal optical sensor as the second longitudinal optical sensor. As described above, by recording at least one object by both the first longitudinal optical sensor and the second longitudinal optical sensor it will be possible to resolve the ambiguity in the known relationship between the beam cross-section of the light beam and the longitudinal position of the at least one object, wherein the resolving of the ambiguity may work separately for each color which may be recorded. In addition, it may be advantageous to set a first signal recorded by the first longitudinal optical sensor in relationship to a second signal recorded by the last or second longitudinal optical sensor, such as by calculating a quotient or another related relationship. A result obtained by creating such a relationship may particularly facilitate the recognition of a certain color by this arrangement.

As outlined above, the intransparent last longitudinal optical sensor may be a large-area sensor having a single sensitive area or may comprise at least one matrix of pixels, i.e. may be a pixelated optical sensor or imaging sensor. In a further preferred embodiment, the pixels themselves may be equipped with different spectral sensitivity which may allow them to become

sensitive to a specific color. Hereby, the specific colors may be distributed over the area of the last longitudinal optical sensor in any fashion, for example in a random fashion. However, an arrangement is preferred wherein pixels with sensitivity to a specific color are placed in an alternating fashion over the area of the intransparent last longitudinal optical sensor. By way of example, two, three, or four pixels with different sensitivity, e.g. three pixels with a specific sensitivity to red, green, and blue, alternate each other in a one-dimensional or, preferably, in a two-dimensional manner, over the area of the last longitudinal optical sensor. This arrangement may further be interrupted by white pixels, i.e. pixels which exhibit a spectral sensitivity over a large spectral range, e.g. over the visible spectrum, or over a spectrum which may include infrared or ultraviolet shares.

In a further preferred embodiment, the detector may be adapted, such as by using at least one optically sensitive element. As further used herein, the "optically sensitive element" may be considered as an arbitrary optical element which may be sensitive to a specific value of an optical property or to a specific range of values of the optical property of the light beam which may impinge on the optically sensitive element in a manner that the specific value of the optical property or to the specific range of values of the optical property is preferred with regard to other values of the light beam. The optical property as employed here may be selected from the group referring to the light beam and consisting of: a wavelength, a phase, and a polarization. Thus, the optically sensitive element may be designated as a wavelength-sensitive element, a phase-sensitive element, and/or a polarization-sensitive element, respectively. Examples for wavelength-sensitive elements may comprise one or more of a prism, a grating, a dichroitic mirror, a color wheel, or a color drum.

By using the optically sensitive element, the light beam may be influenced by an optical effect related to the at least one optical property immediately before an interaction, during the interaction and/or immediately after the interaction of the light beam with the optically sensitive element. Consequently, an expression like "passing through the optically sensitive element" may refer to a time period during which the light beam may interact with the respective element. In general, the optically sensitive element may induce the optical effect on the light beam impinging on the optically sensitive element, such as by altering a transmission or a reflectance of the impinging light beam.

Within this particular embodiment, for sequentially detecting detector signals for the different optical properties, such as different colors, different phases, and/or different polarizations, the at least one optically sensitive element may be adapted to sequentially influence the light beam. As an example for a sequential process, a rotating filter wheel may be used having filter segments of different transmission properties, for periodically influencing the light beam. Thus, each cycle of rotation of the filter wheel may be split into time segments, wherein each segment may correspond to a different optical property, such as to a different color, a different phase and/or a different polarization. With regard to a filter wheel wherein each segment corresponds to a different polarization, the filter wheel may preferably exhibit an elliptical polarization, in

particular a circular polarization, which may be changing along the circumference of the filter wheel, for example in a discrete or in a continuous manner. However, other embodiments, such as filter wheels which may employ different orientations of a linear polarization within different segments, may be feasible.

5

In general, at least one optical sensor may be placed behind the filter wheel, in order to generate at least one combined detector signal. By evaluating the at least one combined detector signal in a time-resolved fashion, such as by using a phase-sensitive detection, the combined detector signal may be split into partial detector signals corresponding to the different
10 time segments and, thus, corresponding to the different colors of the light beam. Thereby, detector signals for each color, each phase and/or each polarization may be generated, which may correspond to the light beams impinging on the detector. Collecting the data for different optical properties, i.e. different colors or phases or polarizations, from the broadly absorbing stack of optical sensors, may result in acquiring the overall distribution. Consequently, the use
15 of a filter wheel may, therefore, allow determining simultaneously the respective optical property, such as color, phase, or polarization, and intensity and depth by using the detector according to the present invention, thereby avoiding the previous necessity to employ solar cells exhibiting different absorption spectra.

20 Generally, as outlined above, the evaluation device may be adapted to generate the at least one item of information on the longitudinal position of the object by determining a diameter of the light beam from the at least one longitudinal sensor signal. As used herein and as used in the following, the diameter of the light beam or, equivalently, a beam waist of the light beam might be used to characterize the beam cross-section of the light beam at a specific location. As
25 outlined above, a known relationship might be used between the longitudinal position of the object and the beam cross-section in order to determine the longitudinal position of the object by evaluating the at least one longitudinal sensor signal. As an example, as outlined above, a Gaussian relationship might be used, assuming that the light beam propagates at least approximately in a Gaussian Manner. For this purpose, the light beam might be shaped
30 appropriately, such as by using an illumination source generating a light beam having known propagation properties, such as a known Gaussian profile. For this purpose, the illumination source itself may generate the light beam having the known properties, which, for example, is the case for many types of lasers, as the skilled person knows. Additionally or alternatively, the illumination source and/or the detector may have one or more beam-shaping elements, such as
35 one or more lenses and/or one or more diaphragms, in order to provide a light beam having known properties, as the skilled person will recognize. Thus, as an example, one or more transfer elements may be provided, such as one or more transfer elements having known beam-shaping properties. Additionally or alternatively, the illumination source and/or the detector, such as the at least one optional transfer element, may have one or more wavelength-
40 selective elements, such as one or more filters, such as one or more filter elements for filtering out wavelengths outside an excitation maximum of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor.

Thus, generally, the evaluation device may be adapted to compare the beam cross-section and/or the diameter of the light beam with known beam properties of the light beam in order to determine the at least one item of information on the longitudinal position of the object,
5 preferably from a known dependency of a beam diameter of the light beam on at least one propagation coordinate in a direction of propagation of the light beam and/or from a known Gaussian profile of the light beam.

In a specific embodiment, the evaluation device is adapted to determine a number N of pixels of
10 at least one pixelated optical sensor of the detector, such as of the last longitudinal optical sensor, which are illuminated by the light beam, the evaluation device further being adapted to determine at least one longitudinal coordinate of the object by using the number N of pixels which are illuminated by the light beam. Therefore, the evaluation device may be adapted to compare, for each of the pixels, the signal to at least one threshold in order to determine
15 whether the pixel is an illuminated pixel or not. This at least one threshold may be an individual threshold for each of the pixels or may be a threshold which is a uniform threshold for the whole matrix. In case a plurality of optical sensors is provided, at least one threshold may be provided for each of the optical sensors and/or for a group comprising at least two of the optical sensors, wherein, for two optical sensors, their respective thresholds may be identical or different. Thus,
20 for each of the optical sensors, an individual threshold may be provided. The threshold may be predetermined and/or fixed. Alternatively, the at least one threshold may be variable. Thus, the at least one threshold may be determined individually for each measurement or groups of measurements. Thus, at least one algorithm may be provided adapted to determine the threshold.

25 The evaluation device may generally be adapted to determine at least one pixel having the highest illumination out of the pixels by comparing the signals of the pixels. Thus, the detector generally may be adapted to determine one or more pixels and/or an area or region of the matrix having the highest intensity of the illumination by the light beam. As an example, in this
30 way, a center of illumination by the light beam may be determined. The highest illumination and/or the information about the at least one area or region of highest illumination may be used in various ways. Thus, as outlined above, the at least one above-mentioned threshold may be a variable threshold. As an example, the evaluation device may be adapted to choose the above-mentioned at least one threshold as a fraction of the signal of the at least one pixel having the
35 highest illumination. Thus, the evaluation device may be adapted to choose the threshold by multiplying the signal of the at least one pixel having the highest illumination with a factor of $1/e^2$. This option is particularly preferred in case Gaussian propagation properties are assumed for the at least one light beam, since the threshold $1/e^2$ generally determines the borders of a light spot having a beam radius or beam waist generated by a Gaussian light beam on the
40 optical sensor.

A further aspect of the present invention makes use of at least two detectors according to the present invention, wherein each of such detectors may be selected as of at least one detector according to one or more of the embodiments disclosed above or disclosed in further detail below. Thus, for optional embodiments of the method, reference might be made to the
5 respective embodiments of the detector.

In a preferred embodiment, the at least one object might be illuminated by using at least one illumination source which generates primary light, wherein the at least one object elastically or inelastically reflects the primary light, thereby generating a plurality of light beams which
10 propagate to one of the at least two detectors. The at least one illumination source may form or may not form a constituent part of each of the at least two detectors which. Thus, the at least one illumination source may be formed independently of the at least two detectors and may, therefore, particularly be located in at least one position which is separated from the at least two detectors. By way of example, the at least one illumination source itself may be or may
15 comprise an ambient light source and/or may be or may comprise an artificial illumination source. This embodiment is preferably suited for an application in which at least two detectors, preferentially two identical detectors, are employed for acquiring depth information, in particular, for the purpose to providing a measurement volume which extends the inherent measurement volume of a single detector.

The inherent measurement volume of a single detector may, in many cases, be described as an approximate half-cone, wherein a first object which is located within the inherent measurement volume may be detected by the single detector whereas a second object which is located outside the inherent measurement volume can principally not be detected by the single
20 detector. The conical surface of the approximate half-cone can be considered to be formed by a virtual reverse light beam which would be emitted by the at least one optical sensor. The virtual reverse light beam would, thus, emerge from the surface of the at least one optical sensor which, however, does not constitute a point source but rather an extended area. From simple geometrical considerations it can be deduced that no virtual reverse light beam emitted by the
25 at least one optical sensor in this manner will be able to reach all positions in all directions in the volume which surrounds the at least one optical sensor. However, the locations which may be virtually hit by the virtual reverse light beam form an approximate half-cone which can be described as the inherent measurement volume of the single detector.

Therefore, in order to be able to cover a large measurement volume which exceeds the inherent measurement volume of a single detector, at least two detectors may be used, wherein the at least two detectors may be identical or may differ from each other with respect to at least one certain technical property as described elsewhere. In general, the large measurement volume comprises an overlapping volume, which denotes a region in space, which may be coherent or
30 not, wherein double or even multiple detection may occur, i.e. a specific object may be detected by two or more detectors independently, at the same time or at different times. Even in case when two or more detectors, particularly two or more identical detectors, are employed, the
35

double or multiple detection of a specific object does not destroy a reliable acquisition of the depth information about the specific object in the overlapping volume. Since the at least one illumination source may be formed independently of the at least two detectors, typically, no relationship exists between a specific illumination source and a specific detector. Therefore, a reliable acquisition of the depth information will also be possible when at least two of the detectors point towards each other. As a result of this disconnection between the specific illumination source and the specific detector, the recording of the depth information about the specific object will not be impaired when the specific object may be located in the overlapping volume. On the contrary, the depth information in the overlapping volume which concerns a specific object may independently been acquired by more than one detector at the same time and can, thus, be used to improve the accuracy of the depth measurement for the specific object. By way of example, this improvement may be achieved by comparing respective depth values which are recorded simultaneously or successively for the same object by at least two separate single detectors.

In a further aspect of the present invention, a human-machine interface for exchanging at least one item of information between a user and a machine is proposed. The human-machine interface as proposed may make use of the fact that the above-mentioned detector in one or more of the embodiments mentioned above or as mentioned in further detail below may be used by one or more users for providing information and/or commands to a machine. Thus, preferably, the human-machine interface may be used for inputting control commands.

The human-machine interface comprises at least one detector according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments as disclosed in further detail below, wherein the human-machine interface is designed to generate at least one item of geometrical information of the user by means of the detector wherein the human-machine interface is designed to assign to the geometrical information at least one item of information, in particular at least one control command.

Generally, as used herein, the at least one item of geometrical information of the user may imply one or more items of information on a transversal position and/or on a longitudinal position of the user and/or one or more body parts of the user. Thus, preferably, the geometrical information of the user may imply one or more items of information on a transversal position and/or a longitudinal position as provided by the evaluation device of the detector. The user, a body part of the user or a plurality of body parts of the user may be regarded as one or more objects which may be detected by the at least one detector. Therein, precisely one detector may be provided, or a combination of a plurality of detectors may be provided. As an example, a plurality of detectors may be provided for determining positions of a plurality of body parts of the user and/or for determining an orientation of at least one body part of the user. The human-machine interface may comprise one or more detectors, wherein, in case a plurality of detectors is provided, the detectors may be identical or may differ. Herein, in case a plurality of detectors

is used, the plurality of detectors, particularly the plurality of identical detectors, still allows for a reliable acquisition of depth information about the at least one object in an overlapping volume which may be recorded, as described above, by the plurality of detectors.

- 5 Thus, preferably, the at least one item of geometrical information of the user is selected from the group consisting of: a position of a body of the user; a position of at least one body part of the user; an orientation of a body of the user; an orientation of at least one body part of the user.
- 10 The human-machine interface may further comprise at least one beacon device connectable to the user. As used herein, a beacon device generally is an arbitrary device which may be detected by the at least one detector and/or which facilitates detection by the at least one detector. Thus, as will be outlined in further detail below, the beacon device may be an active beacon device adapted for generating the at least one light beam to be detected by the
- 15 detector, such as by having one or more illumination sources for generating the at least one light beam. Additionally or alternatively, the beacon device may fully or partially be designed as a passive beacon device, such as by providing one or more reflective elements adapted to reflect a light beam generated by a separate illumination source. The at least one beacon device may permanently or temporarily be attached to the user. The attachment may take place
- 20 by using one or more attachment means and/or by the user himself or herself, such as by the user holding the at least one beacon device by hand and/or by the user wearing the beacon device.

- The human-machine interface may be adapted such that the detector may generate an
- 25 information on the position of the at least one beacon device. Specifically in case a manner of attachment of the at least one beacon device to the user is known, from the at least one item of information on the position of the at least one beacon device at least one item of information regarding a position and/or an orientation of the user or one or more body parts of the user may be gained.

- 30 The beacon device preferably is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user. As outlined above, the beacon device may fully or partially be designed as an active beacon device. Thus, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be
- 35 transmitted to the detector, preferably at least one light beam having known beam properties. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

- 40 The beacon device preferably may comprise at least one of: a garment to be worn by the user, preferably a garment selected from the group consisting of a glove, a jacket, a hat, shoes,

trousers and a suit; a stick that may be held by hand; a bat; a club; a racket; a cane; a toy, such as a toy gun.

5 In a further aspect of the present invention, an entertainment device for carrying out at least one entertainment function is disclosed. As used herein, an entertainment device is a device which may serve the purpose of leisure and/or entertainment of one or more users, in the following also referred to as one or more players. As an example, the entertainment device may serve the purpose of gaming, preferably computer gaming. Additionally or alternatively, the entertainment device may also be used for other purposes, such as for exercising, sports, physical therapy or
10 motion tracking in general. Thus, the entertainment device may be implemented into a computer, a computer network or a computer system or may comprise a computer, a computer network or a computer system which runs one or more gaming software programs.

15 The entertainment device comprises at least one human-machine interface according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed below. The entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface. The at least one item of information may be transmitted to and/or may be used by a controller and/or a computer of the entertainment device.

20 The at least one item of information preferably may comprise at least one command adapted for influencing the course of a game. Thus, as an example, the at least one item of information may include at least one item of information on at least one of a movement, the orientation and a position of the player and/or of one or more body parts of the player, thereby allowing for the player to simulate a specific position and/or action required for gaming. As an example, one or
25 more of the following movements may be simulated and communicated to a controller and/or a computer of the entertainment device: dancing; running; jumping; swinging of a racket; swinging of a bat; swinging of a club; pointing of an object towards another object, such as pointing of a toy gun towards a target.

30 The entertainment device, preferably a controller and/or a computer of the entertainment device, is designed to vary the entertainment function in accordance with the information. Thus, as outlined above, a course of a game might be influenced in accordance with the at least one item of information. Thus, the entertainment device might include one or more controllers which
35 might be separate from the evaluation device of the at least one detector and/or which might be fully or partially identical to the at least one evaluation device or which might even include the at least one evaluation device. Preferably, the at least one controller might include one or more data processing devices, such as one or more computers and/or microcontrollers.

40 In a further embodiment of the present invention, the entertainment device may be part of an equipment, the equipment being a mobile piece or, in particular, an immobile piece, wherein the equipment may at least partially incorporate the entertainment device. The equipment may

include a single, separate piece being located at a position, either a fixed position or a position at least intermittently subject to a variation, but the equipment may also comprise at least two pieces, preferably two to ten pieces, such as three, four, five, or six pieces, wherein the at least two pieces may be distributed over at least two positions differing from each other within an area, such as a room or a part thereof. Hereby, the entertainment device may be part of the equipment, wherein preferably some or each piece of the equipment may exhibit a part of the entertainment device, e.g. in such a manner that some or each piece of the equipment may comprise at least one detector according to the present invention or a part thereof, such as a sensor. As used herein, "immobile equipment" may include an immobile electronic article, in particular, designated as consumer electronics, wherein "consumer electronics" comprises electronic articles preferentially intended for everyday use, mainly in entertainment, communications and office matters, such as radio receivers, monitors, television sets, audio players, video players, personal computers and/or telephones. A particular example constituting the immobile equipment may be a surround system, which may for example be formed by a number of two, three, four, five, six or more separate pieces of the equipment, such as individual monitors or audio players, including loudspeakers, which may be distributed over an area, preferentially in a specific fashion, such as forming an arc-shaped assembly enclosing a room or a part thereof.

Additionally or alternatively, the entertainment device or a part thereof, such as one, some or each piece of the equipment, may further be equipped with one or more of the following devices: a photographic device, such as a camera, particularly a 2D camera, a picture analysis software, particularly a 2D picture analysis software, and a reference object, particularly a geometrically symmetric reference object, such as a book or a specially formed toy. Hereby, the reference object may also be a part of the immobile equipment and fulfill a further function of the entertainment device as described above and/or below, wherein the reference object may further comprise a detector, a 2D camera or another photographic device. Preferably, a constructive interaction of the photographic device, the picture analysis software and the particularly symmetric reference object, may facilitate an alignment of a 2D picture of an object in question as recorded by the photographic device with the 3D position of the same object as determined by the at least one detector.

In a further embodiment of the present invention, the object which may constitute a target of the at least one detector comprised within the at least one human-machine interface of the entertainment device, may be part of a controller as comprised within mobile equipment, wherein the mobile equipment may be configured to control another mobile equipment or immobile equipment. As used herein, "mobile equipment" may, thus, include mobile electronic articles, in particular, designated as consumer electronics, such as mobile phones, radio receivers, video recorders, audio players, digital cameras, camcorders, mobile computers, video game consoles and/or other devices adapted for remote control. This embodiment may particularly allow controlling immobile equipment with any kind of mobile equipment, preferably with a lesser number of pieces of equipment. As a non-limiting example, it may, thus, be

possible to simultaneously control for example both a game console and a television set by using a mobile phone.

5 Additionally or alternatively, the object which may constitute the target of the detector may further be equipped with an additional sensor (apart from the sensors as comprised within the detector) particularly configured for determining a physical and/or chemical quantity related to the object, such as an inertia sensor for measuring the inertial motion of the object, or an acceleration sensor for determining the acceleration of the object. However, besides these preferred examples, other kinds of sensors adapted for acquiring further parameter related to
10 the object, such as a vibrational sensor for determining vibrations of the object, a temperature sensor for recording the temperature of the object, or a humidity sensor for recording the humidity of the object may be employed. An application of the additional sensor within the object may allow improving the quality and/or the scope of the detection of the position of the object. As a non-limiting example, the additional inertia sensor and/or acceleration sensor may
15 particularly be configured to record additional movements of the object, such as a rotation of the object, which may particularly be employed for increasing the accuracy of the object detection. Moreover, the additional inertia sensor and/or acceleration sensor may preferentially still be addressed in a case where the object being equipped with at least one of these sensors may leave a visual range of the detector comprised within the human-machine interface of the
20 entertainment device. In this case, it might, nevertheless, be possible to follow the object after the object may have left the visual range of the detector by still being able to recording signals emitted from at least one of these sensors and using these signals for determining the location of the object by taking into account its actual inertia and acceleration values and calculating the position therefrom.

25 Additionally or alternatively, the object which may constitute the target of the detector may further be equipped with a further feature allowing both to simulate and/or to stimulate motions, for example by simulating motions of the object, wherein the object may be virtual or real and wherein the object may be controlled by a controller, and/or by stimulating motions of the object
30 by applying the controller accordingly. This feature may particularly be employed for providing a more realistic entertainment experience for a user. As an illustrating example, a steering wheel as employed in an entertainment device may vibrate, wherein the amplitude of the vibrations may depend on a nature of a ground on which a virtual car may be driving on. As a further embodiment, the motion of the object may be stimulated by employing a gyroscope, which may
35 be used for example for a stabilization of flying vehicles as described under the address en.wikipedia.org/wiki/gyroscope.

In a further embodiment of the present invention, the object which may constitute the target of the at least one detector may be equipped with at least one modulation device for modulating
40 the illumination, in particular for a periodic modulation. Preferably, the object may comprise at least one illumination source, which may be part of the object or, alternatively or additionally, be held by the object or attached thereto and which may act as a beacon in a manner as described

elsewhere in this application. The illumination may be adapted to generate at least one light beam to be transmitted to the detector, whereby the illumination source comprises a modulation device for modulating the illumination and/or the modulation device may be a separate device configured for controlling the emission of the illumination source. According to this embodiment, 5 apart from the fundamental modulation of the illumination source, the modulation device may generate additional modulation frequencies, also be denoted as "overtones", which might be used for transmitting any item of additional information or data from the object to the detector. This embodiment, which might also be designated as a "modulating retro-reflector", may open the way to employ the object equipped with the modulation device configured for generating 10 both the fundamental and the additional modulation frequencies as remote control. Further, an already existing remote control may be replaced by the object equipped with the described modulation device. Against this background, this kind of object and a piece configured for remote control may interchangeably be used within an arrangement incorporating a detector according to the present invention.

15 In a further embodiment of the present invention, the entertainment device may further be equipped with additional items such as items commonly used within such an environment. Glasses or other devices being configured for creating a 3D vision within the mind of a player may constitute a particular example.

20 In a further embodiment of the present invention, the entertainment device may further be equipped with an augmented reality application. As further used herein, "augmented reality" may describe a live perception of reality comprising elements which may be modified by computer-generated data primarily related to physical phenomena such as sound, images, or 25 others. An example may be vision glasses which are particularly adapted for augmented reality applications. Another example may include an arrangement comprising at least two detectors, preferably a multitude thereof, wherein the detectors may particularly be arranged to cover an area within a room or a preferably large part thereof, a photographic device, such as a camera, particularly a 2D camera, and an augmented reality application, wherein the arrangement might 30 be employed to transform a real area into a playing field, which may also be designated as an entertainment field.

In a further aspect of the present invention, a tracking system for tracking the position of at least one movable object is provided. As used herein, a tracking system is a device which is adapted 35 to gather information on a series of past positions of the at least one object or at least one part of an object. Additionally, the tracking system may be adapted to provide information on at least one predicted future position of the at least one object or the at least one part of the object. The tracking system may have at least one track controller, which may fully or partially be embodied as an electronic device, preferably as at least one data processing device, more preferably as at 40 least one computer or microcontroller. Again, the at least one track controller may comprise the at least one evaluation device and/or may be part of the at least one evaluation device and/or may fully or partially be identical to the at least one evaluation device.

The tracking system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The tracking system further comprises at least one track controller. The tracking system may comprise one, two or more detectors, particularly two or more identical detectors, which allow for a reliable acquisition of depth information about the at least one object in an overlapping volume between the two or more detectors. The track controller is adapted to track a series of positions of the object, each position comprising at least one item of information on a transversal position of the object at a specific point in time and at least one item of information on a longitudinal position of the object at a specific point in time.

The tracking system may further comprise at least one beacon device connectable to the object. For a potential definition of the beacon device, reference may be made to the disclosure above. The tracking system preferably is adapted such that the detector may generate an information on the position of the object of the at least one beacon device. For potential embodiments of the beacon device, reference may be made to the disclosure above. Thus, again, the beacon device may fully or partially be embodied as an active beacon device and/or as a passive beacon device. As an example, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be transmitted to the detector. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

The tracking system may be adapted to initiate one or more actions of the tracking system itself and/or of one or more separate devices. For the latter purpose, the tracking system, preferably the track controller, may have one or more wireless and/or wire-bound interfaces and/or other types of control connections for initiating at least one action. Preferably, the at least one track controller may be adapted to initiate at least one action in accordance with at least one actual position of the object. As an example, the action may be selected from the group consisting of: a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.

As an example of application of a tracking system, the tracking system may be used for continuously pointing at least one first object to at least one second object even though the first object and/or the second object might move. Potential examples, again, may be found in industrial applications, such as in robotics and/or for continuously working on an article even though the article is moving, such as during manufacturing in a manufacturing line or assembly line. Additionally or alternatively, the tracking system might be used for illumination purposes, such as for continuously illuminating the object by continuously pointing an illumination source to the object even though the object might be moving. Further applications might be found in

communication systems, such as in order to continuously transmit information to a moving object by pointing a transmitter towards the moving object.

5 In a further aspect of the present invention, a camera for imaging at least one object is disclosed. The camera comprises at least one detector according to the present invention, such as disclosed in one or more of the embodiments given above or given in further detail below.

10 Thus, specifically, the present application may be applied in the field of photography. Thus, the detector may be part of a photographic device, specifically of a digital camera. Specifically, the detector may be used for 3D photography, specifically for digital 3D photography. Thus, the detector may form a digital 3D camera or may be part of a digital 3D camera. As used herein, the term "photography" generally refers to the technology of acquiring image information of at least one object. As further used herein, a "camera" generally is a device adapted for performing photography. As further used herein, the term "digital photography" generally refers to the technology of acquiring image information of at least one object by using a plurality of light-sensitive elements adapted to generate electrical signals indicating an intensity and/or color of illumination, preferably digital electrical signals. As further used herein, the term "3D photography" generally refers to the technology of acquiring image information of at least one object in three spatial dimensions. Accordingly, a 3D camera is a device adapted for performing 20 3D photography. The camera generally may be adapted for acquiring a single image, such as a single 3D image, or may be adapted for acquiring a plurality of images, such as a sequence of images. Thus, the camera may also be a video camera adapted for video applications, such as for acquiring digital video sequences.

25 Thus, generally, the present invention further refers to a camera, specifically a digital camera, more specifically a 3D camera or digital 3D camera, for imaging at least one object. As outlined above, the term imaging, as used herein, generally refers to acquiring image information of at least one object. The camera comprises at least one detector according to the present invention. The camera, as outlined above, may be adapted for acquiring a single image or for 30 acquiring a plurality of images, such as image sequence, preferably for acquiring digital video sequences. Thus, as an example, the camera may be or may comprise a video camera. In the latter case, the camera preferably comprises a data memory for storing the image sequence.

35 As used within the present invention, the expression "position" generally refers to at least one item of information regarding one or more of an absolute position and an orientation of one or more points of the object. Thus, specifically, the position may be determined in a coordinate system of the detector, such as in a Cartesian coordinate system. Additionally or alternatively, however, other types of coordinate systems may be used, such as polar coordinate systems and/or spherical coordinate systems.

40

In a further aspect of the present invention, a method for determining a position of at least one object is disclosed. The method preferably may make use of at least one detector according to

the present invention, such as of at least one detector according to one or more of the embodiments disclosed above or disclosed in further detail below. Thus, for optional embodiments of the method, reference might be made to the embodiments of the detector.

- 5 The method comprises the following steps, which may be performed in the given order or in a different order. Further, additional method steps might be provided which are not listed. Further, two or more or even all of the method steps might be performed at least partially simultaneously. Further, two or more or even all of the method steps might be performed twice or even more than twice, repeatedly.

10

In a first method step, which might also be referred to as a step of determining at least one transversal position, at least one transversal optical sensor is used. The transversal optical sensor determines a transversal position of at least one light beam traveling from the object to the detector, wherein the transversal position is a position in at least one dimension
15 perpendicular to an optical axis of the detector. The transversal optical sensor generates at least one transversal sensor signal.

20

In a further method step, which might also be referred to as a step of determining at least one longitudinal position, at least one longitudinal optical sensor is used. The longitudinal optical sensor has at least one sensor region. The longitudinal optical sensor generates at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region by the light beam. The longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam in the sensor region.

25

In a further method step, which might also be referred to as an evaluation step, at least one evaluation device is used. The evaluation device generates at least one item of information on a transversal position of the object by evaluating the transversal sensor signal and wherein the evaluation device further generates at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal.

30

In a further aspect of the present invention, a use of a detector according to the present invention is disclosed. Therein, a use of the detector for a purpose of use is proposed, selected from the group consisting of: a distance measurement, in particular in traffic technology; a position measurement, in particular in traffic technology; an entertainment application; a security
35 application; a human-machine interface application; a tracking application; a photography application; an imaging application or camera application; a mapping application for generating maps of at least one space.

40

In the following, some additional remarks regarding potential embodiments of the detector, the human-machine interface, the tracking system and the method according to the present invention are given. As outlined above, preferably, for potential details of the setups of the at least one transversal optical detector and the at least one longitudinal optical detector,

reference may be made to WO 2012/110924 A1, specifically with regard to potential electrode materials, organic materials, inorganic materials, layer setups and further details.

5 The object can generally be a living or else inanimate object. Examples of objects which can be detected completely or partly by means of the detector are described in even greater detail below.

Further, with regard to potential embodiments of the optional transfer device, reference may be made to WO 2012/110924 A1. Thus, this optional transfer device can comprise for example at
10 least one beam path. The transfer device can for example comprise one or a plurality of mirrors and/or beam splitters and/or beam deflecting elements in order to influence a direction of the electromagnetic radiation. Alternatively or additionally, the transfer device can comprise one or a plurality of imaging elements which can have the effect of a converging lens and/or a diverging lens. By way of example, the optional transfer device can have one or a plurality of
15 lenses and/or one or a plurality of convex and/or concave mirrors. Once again alternatively or additionally, the transfer device can have at least one wavelength-selective element, for example at least one optical filter. Once again alternatively or additionally, the transfer device can be designed to impress a predefined beam profile on the electromagnetic radiation, for example, at the location of the sensor region and in particular the sensor area. The
20 abovementioned optional embodiments of the optional transfer device can, in principle, be realized individually or in any desired combination.

Further, generally, it shall be noted that, in the context of the present invention, an optical
25 sensor may refer to an arbitrary element which is designed to convert at least one optical signal into a different signal form, preferably into at least one electrical signal, for example a voltage signal and/or a current signal. In particular the optical sensor can comprise at least one optical-electrical converter element, preferably at least one photodiode and/or at least one solar cell. As is explained in even greater detail below, in the context of the present invention, preference is attached particularly to a use of at least one organic optical sensor, that is to say an optical
30 sensor which comprises at least one organic material, for example at least one organic semiconductor material.

In the context of the present invention, a sensor region should be understood to mean a two-dimensional or three-dimensional region which preferably, but not necessarily, is continuous
35 and can form a continuous region, wherein the sensor region is designed to vary at least one measurable property, in a manner dependent on the illumination. By way of example, said at least one property can comprise an electrical property, for example, by the sensor region being designed to generate, solely or in interaction with other elements of the optical sensor, a photo voltage and/or a photocurrent and/or some other type of signal. In particular, the sensor region
40 can be embodied in such a way that it generates a uniform, preferably a single, signal in a manner dependent on the illumination of the sensor region. The sensor region can thus be the smallest unit of the optical sensor for which a uniform signal, for example, an electrical signal, is

generated, which preferably can no longer be subdivided to partial signals, for example for partial regions of the sensor region. The transversal optical sensor and/or the longitudinal optical sensor each can have one or else a plurality of such sensor regions, the latter case for example by a plurality of such sensor regions being arranged in a two-dimensional and/or three-dimensional matrix arrangement.

The at least one sensor region can comprise for example at least one sensor area, that is to say a sensor region whose lateral extent considerably exceeds the thickness of the sensor region, for example by at least a factor of 10, preferably by at least a factor of 100 and particularly preferably by at least a factor of 1000. Examples of such sensor areas can be found in organic or inorganic photovoltaic elements, for example, in accordance with the prior art described above, or else in accordance with the exemplary embodiments described in even greater detail below. The detector can have one or a plurality of such optical sensors and/or sensor regions. By way of example, a plurality of optical sensors can be arranged linearly in a spaced-apart manner or in a two-dimensional arrangement or else in a three-dimensional arrangement, for example by a stack of photovoltaic elements being used, preferably organic photovoltaic elements, preferably a stack in which the sensor areas of the photovoltaic elements are arranged parallel to one another. Other embodiments are also possible.

The optional transfer device can, as explained above, be designed to feed light propagating from the object to the detector to the transversal optical sensor and/or the longitudinal optical sensor, preferably successively. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the transversal and/or longitudinal optical sensor. The optional transfer device can also, as explained in even greater detail below, be wholly or partly a constituent part of at least one optional illumination source, for example by the illumination source being designed to provide a light beam having defined optical properties, for example having a defined or precisely known beam profile, for example at least one Gaussian beam, in particular at least one laser beam having a known beam profile.

For potential embodiments of the optional illumination source, reference may be made to WO 2012/110924 A1. Still, other embodiments are feasible. Light emerging from the object can originate in the object itself, but can also optionally have a different origin and propagate from this origin to the object and subsequently toward the transversal and/or longitudinal optical sensor. The latter case can be effected for example by at least one illumination source being used. This illumination source can for example be or comprise an ambient light source and/or may be or may comprise an artificial illumination source. By way of example, the detector itself can comprise at least one illumination source, for example at least one laser and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. On account of their generally defined beam profiles and other properties of handleability, the use of one or a

plurality of lasers as illumination source or as part thereof, is particularly preferred. The illumination source itself can be a constituent part of the detector or else be formed independently of the detector. The illumination source can be integrated in particular into the detector, for example a housing of the detector. Alternatively or additionally, at least one illumination source can also be integrated into the object or connected or spatially coupled to the object.

The light emerging from the object can accordingly, alternatively or additionally from the option that said light originates in the object itself emerge from the illumination source and/or be excited by the illumination source. By way of example, the electromagnetic light emerging from the object can be emitted by the object itself and/or be reflected by the object and/or be scattered by the object before it is fed to the optical sensor. In this case, emission and/or scattering of the electromagnetic radiation can be effected without spectral influencing of the electromagnetic radiation or with such influencing. Thus, by way of example, a wavelength shift can also occur during scattering, for example according to Stokes or Raman. Furthermore, emission of light can be excited, for example, by a primary light source, for example by the object or a partial region of the object being excited to effect luminescence, in particular phosphorescence and/or fluorescence. Other emission processes are also possible, in principle. If a reflection occurs, then the object can have for example at least one reflective region, in particular at least one reflective surface. Said reflective surface can be a part of the object itself, but can also be for example a reflector which is connected or spatially coupled to the object, for example a reflector plaque connected to the object. If at least one reflector is used, then it can in turn also be regarded as part of the detector which is connected to the object, for example, independently of other constituent parts of the detector.

The at least one illumination source of the detector can generally be adapted to the emission and/or reflective properties of the object, for example in terms of its wavelength. Various embodiments are possible.

The at least one optional illumination source generally may emit light in at least one of: the ultraviolet spectral range, preferably in the range of 200 nm to 380 nm; the visible spectral range (380 nm to 780 nm); the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers. Most preferably, the at least one illumination source is adapted to emit light in the visible spectral range, preferably in the range of 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm.

The feeding of the light to the transversal and/or longitudinal optical sensor can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is produced on the optional sensor area of the transversal and/or longitudinal optical sensor. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects can be detected. Preferably, the optional transfer device is designed in such a way that the light spot, for example

in the case of an object arranged within a visual range of the detector, is arranged completely on the sensor region, in particular the sensor area. By way of example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

5 The at least one longitudinal optical sensor, as outlined above, can be designed for example in such a way that the longitudinal sensor signal, given the same power of the illumination, that is to say for example given the same integral over the intensity of the illumination on the sensor area, is dependent on the geometry of the illumination, that is to say for example on the diameter and/or the equivalent diameter for the sensor spot. By way of example, the longitudinal
10 optical sensor can be designed in such a way that upon a doubling of the beam cross section given the same total power, a signal variation occurs by at least a factor of 3, preferably by at least a factor of 4, in particular a factor of 5 or even a factor of 10. This condition can hold true for example for a specific focusing range, for example for at least one specific beam cross section. Thus, by way of example, the longitudinal sensor signal can have, between at least one
15 optimum focusing at which the signal can have for example at least one global or local maximum and a focusing outside said at least one optimum focusing, a signal difference by at least a factor of 3, preferably by at least a factor of 4, in particular a factor of 5 or even a factor of 10. In particular, the longitudinal sensor signal can have as a function of the geometry of the illumination, for example of the diameter or equivalent diameter of a light spot, at least one
20 pronounced maximum, for example with a boost by at least a factor of 3, particularly preferably by at least a factor of 4 and particularly preferably by at least a factor of 10. Consequently, the longitudinal optical sensor may be based on the above-mentioned FiP-effect, which is disclosed in great detail in WO 2012/110924 A1. Thus, specifically in sDSCs, the focusing of the light beam may play a decisive role, i.e. the cross-section or cross-sectional area on which a certain
25 number of photons (nph) is incident. The more tightly the light beam is focused, i.e. the smaller its cross-section, the higher the photo current may be. The term 'FiP' expresses the relationship between the cross-section ϕ (Fi) of the incident beam and the solar cell's power (P).

30 The at least one longitudinal optical sensor is combined with at least one transversal optical sensor in order to preferably provide appropriate position information of the object.

Such effects of the dependence of the at least one longitudinal sensor signal on a beam geometry, preferably a beam cross-section of the at least one light beam, were observed in the context of the investigations leading to the present invention in particular in the case of organic
35 photovoltaic components, that is to say photovoltaic components, for example, solar cells, which comprise at least one organic material, for example at least one organic p-semiconducting material and/or at least one organic dye. By way of example, such effects, as is explained in even greater detail below by way of example, were observed in the case of dye solar cells, that is to say components which have at least one first electrode, at least one n-semiconducting
40 metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid organic p-type semiconductor, and at least one second electrode. Such dye solar cells, preferably solid dye solar cells (solid dye sensitized solar cells, sDSC), are known in principle in

numerous variations from the literature. The described effect of the dependence of the sensor signal on a geometry of the illumination on the sensor area and a use of this effect have not, however, been described heretofore.

- 5 In particular, the at least one longitudinal optical sensor can be designed in such a way that the sensor signal, given the same total power of the illumination, is substantially independent of a size of the sensor region, in particular of a size of the sensor area, in particular as long as the light spot of the illumination lies completely within the sensor region, in particular the sensor area. Consequently, the longitudinal sensor signal can be dependent exclusively on a focusing
10 of the electromagnetic rays on the sensor area. In particular the sensor signal can be embodied in such a way that a photocurrent and/or a photo voltage per sensor area have/has the same values given the same illumination, for example the same values given the same size of the light spot.
- 15 The evaluation device can comprise in particular at least one data processing device, in particular an electronic data processing device, which can be designed to generate the at least one item of information on the transversal position of the object by evaluating the at least one transversal sensor signal and to generate the at least one item of information on the longitudinal position of the object by evaluating the at least one longitudinal sensor signal. Thus, the
20 evaluation device is designed to use the at least one transversal sensor signal and the at least one longitudinal sensor signal as input variables and to generate the items of information on the transversal position and the longitudinal position of the object by processing these input variables. The processing can be done in parallel, subsequently or even in a combined manner. The evaluation device may use an arbitrary process for generating these items of information,
25 such as by calculation and/or using at least one stored and/or known relationship. Besides the at least one transversal sensor signal and at least one longitudinal sensor signal, one or a plurality of further parameters and/or items of information can influence said relationship, for example at least one item of information about a modulation frequency. The relationship can be determined or determinable empirically, analytically or else semi-empirically. Particularly
30 preferably, the relationship comprises at least one calibration curve, at least one set of calibration curves, at least one function or a combination of the possibilities mentioned. One or a plurality of calibration curves can be stored for example in the form of a set of values and the associated function values thereof, for example in a data storage device and/or a table. Alternatively or additionally, however, the at least one calibration curve can also be stored for
35 example in parameterized form and/or as a functional equation. Separate relationships for processing the at least one transversal sensor signal into the at least one item of information on the transversal position and for processing the at least one longitudinal sensor signal into the at least one item of information on the longitudinal position may be used. Alternatively, at least one combined relationship for processing the sensor signals is feasible. Various possibilities are
40 conceivable and can also be combined.

By way of example, the evaluation device can be designed in terms of programming for the purpose of determining the items of information. The evaluation device can comprise in particular at least one computer, for example at least one microcomputer. Furthermore, the evaluation device can comprise one or a plurality of volatile or nonvolatile data memories. As an
5 alternative or in addition to a data processing device, in particular at least one computer, the evaluation device can comprise one or a plurality of further electronic components which are designed for determining the items of information, for example an electronic table and in particular at least one look-up table and/or at least one application-specific integrated circuit (ASIC).

10 The combination of the at least one item of information on the transversal position and the at least one item of information on the longitudinal position allows for a multiplicity of possible uses of the detector, which will be described by way of example hereinafter. As outlined in great detail in WO 2012/110924 A1, a cross-section of the light beam, resulting in a specific diameter
15 or equivalent diameter of a light spot on the sensor region of the at least one longitudinal optical sensor, can be dependent on a distance between the object and the detector and/or on the optional transfer device of the detector, for example at least one detector lens. By way of example, a variation of the distance between the object and a lens of the optional transfer device can lead to a defocusing of the illumination on the sensor region, accompanied by a
20 change in the geometry of the illumination, for example a widening of a light spot, which can result in a correspondingly altered longitudinal sensor signal or a multiplicity of altered longitudinal sensor signals, in case a plurality of longitudinal optical sensors is used. Even without a transfer device, by way of example, from a known beam profile from the sensor signal and/or a variation thereof, for example, by means of a known beam profile and/or a known
25 propagation of the light beam, it is possible to deduce a defocusing and/or the geometrical information. By way of example, given a known total power of the illumination, it is thus possible to deduce from the longitudinal sensor signal of the longitudinal optical sensor a geometry of the illumination and therefrom in turn the geometrical information, in particular at least one item of location information of the object.

30 Similarly, the at least one transversal optical sensor allows for an easy detection of a transversal position of the object. For this purpose, use may be made of the fact that a change in a transversal position of the object generally will lead to a change in a transversal position of the light beam in the sensor region of the at least one transversal optical sensor. Thus, for
35 example by detecting a transversal position of a light spot generated by the light beam impinging on a sensor region, such as a sensor area, of the transversal optical sensor, the transversal position or at least one item of information on the transversal position of the object may be generated. Thus, the position of the light spot may be determined by comparing currents and/or voltage signals of partial electrodes of the transversal optical sensor, such as by
40 forming at least one ratio of at least two currents through at least two different partial electrodes. For this measurement principle, as an example, reference may be made to US 6,995,445 and/or US 2007/0176165 A1. The above-mentioned at least one relationship between the at

least one transversal sensor signal and the at least one item of information on the transversal position of the object may include a known relationship between a transversal position of the light spot on a sensor region of the transversal optical sensor and a transversal position of the object. For this purpose, known imaging properties of the detector, specifically known imaging properties of at least one transfer device of the detector, may be used. Thus, as an example, the transfer device may include at least one lens, and the known imaging properties may make use of a known lens equation of the lens, thereby allowing for a transformation of at least one transversal coordinate of a light spot into at least one transversal coordinate of the object, as the skilled person will recognize. Therein, the known relationship may also make use of additional information, such as the at least one longitudinal sensor signal and/or the at least one item of information on the longitudinal position of the object. Thus, by using the at least one longitudinal sensor signal, the evaluation device may, as an example, first determine at least one item of information on a lateral position of the object, such as at least one distance between the object and the detector, specifically the transfer device and, more preferably, at least one lens of the transfer device. This item of information on the longitudinal position of the object may then be used in the lens equation in order to transform the at least one transversal sensor signal into the at least one item of information on the transversal position of the object, such as by transforming the at least one transversal coordinate of the light spot in the sensor region of the at least one transversal optical sensor into at least one transversal coordinate of the object. Other algorithms are feasible.

As outlined above, the total intensity of total power of the light beam is often unknown, since this total power e.g. may depend on the properties of the object, such as reflecting properties, and/or may depend on a total power of an illumination source and/or may depend on a large number of environmental conditions. Since the above-mentioned known relationship between the at least one longitudinal optical sensor signal and a beam cross-section of the light beam in the at least one sensor region of the at least one longitudinal optical sensor and, thus, a known relationship between the at least one longitudinal optical sensor signal and the at least one item of information on the longitudinal position of the object may depend on the total power of total intensity of the light beam, various ways of overcoming this uncertainty are feasible. Thus, as outlined in great detail in WO 2012/110924 A1, a plurality of longitudinal sensor signals may be detected by the same longitudinal optical sensor, such as by using different modulation frequencies of an illumination of the object. Thus, at least two longitudinal sensor signals may be acquired at different frequencies of a modulation of the illumination, wherein, from the at least two sensor signals, for example by comparison with corresponding calibration curves, it is possible to deduce the total power and/or the geometry of the illumination, and/or therefrom, directly or indirectly, to deduce the at least one item of information on the longitudinal position of the object.

Additionally or alternatively, however, as outlined above, the detector may comprise a plurality of longitudinal optical sensors, each longitudinal optical sensor being adapted to generate at least one longitudinal sensor signal. The longitudinal sensor signals generated by the

longitudinal optical sensors may be compared, in order to gain information on the total power and/or intensity of the light beam and/or in order to normalize the longitudinal sensor signals and/or the at least one item of information on the longitudinal position of the object for the total power and/or total intensity of the light beam. Thus, as an example, a maximum value of the longitudinal optical sensor signals may be detected, and all longitudinal sensor signals may be divided by this maximum value, thereby generating normalized longitudinal optical sensor signals, which, then, may be transformed by using the above-mentioned known relationship, into the at least one item of longitudinal information on the object. Other ways of normalization are feasible, such as a normalization using a mean value of the longitudinal sensor signals and dividing all longitudinal sensor signals by the mean value. Other options are possible. Each of these options is suited to render the transformation independent from the total power and/or intensity of the light beam. In addition, information on the total power and/or intensity of the light beam might be generated.

The detector described can advantageously be developed in various ways. Thus, the detector can furthermore have at least one modulation device for modulating the illumination, in particular for periodic modulation, in particular a periodic beam interrupting device. A modulation of the illumination should be understood to mean a process in which a total power of the illumination is varied, preferably periodically, in particular with one or a plurality of modulation frequencies. In particular, a periodic modulation can be effected between a maximum value and a minimum value of the total power of the illumination. The minimum value can be 0, but can also be > 0 , such that, by way of example, complete modulation does not have to be effected. The modulation can be effected for example in a beam path between the object and the optical sensor, for example by the at least one modulation device being arranged in said beam path.

Alternatively or additionally, however, the modulation can also be effected in a beam path between an optional illumination source - described in even greater detail below - for illuminating the object and the object, for example by the at least one modulation device being arranged in said beam path. A combination of these possibilities is also conceivable. The at least one modulation device can comprise for example a beam chopper or some other type of periodic beam interrupting device, for example comprising at least one interrupter blade or interrupter wheel, which preferably rotates at constant speed and which can thus periodically interrupt the illumination. Alternatively or additionally, however, it is also possible to use one or a plurality of different types of modulation devices, for example modulation devices based on an electro-optical effect and/or an acousto-optical effect. Once again alternatively or additionally, the at least one optional illumination source itself can also be designed to generate a modulated illumination, for example by said illumination source itself having a modulated intensity and/or total power, for example a periodically modulated total power, and/or by said illumination source being embodied as a pulsed illumination source, for example as a pulsed laser. Thus, by way of example, the at least one modulation device can also be wholly or partly integrated into the illumination source. Various possibilities are conceivable.

The detector can be designed in particular to detect at least two sensor signals in the case of different modulations, in particular at least two sensor signals at respectively different modulation frequencies. The evaluation device can be designed to generate the geometrical information from the at least two sensor signals. As described above, in this way, by way of
5 example, it is possible to resolve ambiguities and/or it is possible to take account of the fact that, for example, a total power of the illumination is generally unknown.

Further possible embodiments of the detector relate to the embodiment of the at least one optional transfer device. As explained above, said at least one transfer device can have imaging
10 properties or else can be embodied as a pure non-imaging transfer device, which has no influence on a focusing of the illumination. It is particularly preferred, however, if the transfer device has at least one imaging element, for example at least one lens and/or at least one curved mirror, since, in the case of such imaging elements, for example, a geometry of the illumination on the sensor region can be dependent on a relative positioning, for example a
15 distance, between the transfer device and the object. Generally, it is particularly preferred if the transfer device is designed in such a way that the electromagnetic radiation which emerges from the object is transferred completely to the sensor region, for example is focused completely onto the sensor region, in particular the sensor area, in particular if the object is arranged in a visual range of the detector.

20

As explained above, the optical sensor can furthermore be designed in such a way that the sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination. The detector can be embodied, in particular, as explained above, in such a way that sensor signals at different modulation frequencies are
25 picked up, for example in order to generate one or a plurality of further items of information about the object. As described above, by way of example, a sensor signal at at least two different modulation frequencies can, in each case, be picked up, wherein, by way of example, in this way, a lack of information about a total power of the illumination can be supplemented. By way of example, by comparing the at least two sensor signals picked up at different
30 modulation frequencies with one or a plurality of calibration curves, which can be stored for example in a data storage device of the detector, even in the case of an unknown total power of the illumination, it is possible to deduce a geometry of the illumination, for example a diameter or an equivalent diameter of a light spot on the sensor area. For this purpose, by way of example, it is possible to use the at least one evaluation device described above, for example at
35 least one data processing data, which can be designed to control such picking-up of sensor signals at different frequencies and which can be designed to compare said sensor signals with the at least one calibration curve in order to generate therefrom the geometrical information, for example information about a geometry of the illumination, for example information about a diameter or equivalent diameter of a light spot of the illumination on a sensor area of the optical
40 sensor. Furthermore, as is explained in even greater detail below, the evaluation device can alternatively or additionally be designed to generate at least one item of geometrical information about the object, for example at least one item of location information. This generation of the at

least one item of geometrical information, as explained above, can be effected for example taking account of at least one known relationship between a positioning of the object relative to the detector and/or the transfer device or a part thereof and a size of a light spot, for example empirically, semi-empirically or analytically using corresponding imaging equations.

5

In contrast to known detectors, in which a spatial resolution and/or imaging of objects is also generally tied to the fact that the smallest possible sensor areas are used, for example the smallest possible pixels in the case of CCD chips, the sensor region of the proposed detector can be embodied in a very large fashion, in principle, since for example the geometrical
10 information, in particular the at least one item of location information, about the object can be generated from a known relationship for example between the geometry of the illumination and the sensor signal. Accordingly, the sensor region can have for example a sensor area, for example an optical sensor area, which is at least 0.001 mm^2 , in particular at least 0.01 mm^2 , preferably at least 0.1 mm^2 , more preferably at least 1 mm^2 , more preferably at least 5 mm^2 ,
15 more preferably at least 10 mm^2 , in particular at least 100 mm^2 or at least 1000 mm^2 or even at least $10\,000 \text{ mm}^2$. In particular, sensor areas of 100 cm^2 or more can be used. The sensor area can generally be adapted to the application. In particular, the sensor area should be chosen in such a way that, at least if the object is situated within a visual range of the detector, preferably within a predefined viewing angle and/or a predefined distance from the detector, the light spot
20 is always arranged within the sensor area. In this way, it can be ensured that the light spot is not trimmed by the limits of the sensor region, as a result of which signal corruption could occur.

As described above, the sensor region can be in particular a continuous sensor region, in particular a continuous sensor area, which can preferably generate a uniform, in particular a
25 single, sensor signal. Consequently, the sensor signal can be in particular a uniform sensor signal for the entire sensor region, that is to say a sensor signal to which each partial region of the sensor region contributes, for example additively. The sensor signal can generally, as explained above, in particular be selected from the group consisting of a photocurrent and a photo voltage.

30

The optical sensor can comprise in particular at least one semiconductor detector and/or be at least one semiconductor detector. In particular, the optical sensor can comprise at least one organic semiconductor detector or be at least one organic semiconductor detector, that is to say a semiconductor detector comprising at least one organic semiconducting material and/or at
35 least one organic sensor material, for example at least one organic dye. Preferably, the organic semiconductor detector can comprise at least one organic solar cell and particularly preferably a dye solar cell, in particular a solid dye solar cell. Exemplary embodiments of such preferred solid dye solar cells are explained in even greater detail below.

40 In particular, the optical sensor can comprise at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably at least one solid p-semiconducting organic material, and at least one second

electrode. Generally, however, it is pointed out that the described effect in which the sensor signal, given a constant total power, is dependent on a geometry of the illumination of the sensor region is with high probability not restricted to organic solar cells and in particular not to dye solar cells. Without intending to restrict the scope of protection of the invention by this theory, and without the invention being bound to the correctness of this theory, it is supposed that generally photovoltaic elements are suitable as optical sensors in which at least one semiconducting material having trap states is used. Consequently, the optical sensor can comprise at least one n-semiconducting material and/or at least one p-semiconducting material which can have for example a conduction band and a valence band, wherein, in the case of organic materials, conduction band and valence band should correspondingly be replaced by LUMO (lowest unoccupied molecular orbital) and HOMO (highest occupied molecular orbital). Trap states should be understood to mean energetically possible states which are disposed between the conduction band (or LUMO) and the valence band (or HOMO) and which can be occupied by charge carriers. By way of example, it is possible to provide trap states for hole conduction which are disposed at at least one distance ΔE_h above the valence band (or HOMO) and/or trap states for electron conduction which are disposed at at least one distance ΔE_e below the conduction band (or LUMO). Such traps can be achieved for example by impurities and/or defects, which can optionally also be introduced in a targeted manner, or can be present intrinsically. By way of example, in the case of a low intensity, that is to say for example in the case of a light spot having a large diameter, only a low current can flow, since firstly the trap states are occupied before holes in the conduction band or electrons in the valence band contribute to a photocurrent. It is only starting from a higher intensity, that is to say for example starting from a more intense focusing of the light spot in the sensor region, that a considerable photocurrent can then flow. The described frequency dependence can be explained for example by the fact that charge carriers leave the traps again after a residence duration τ , such that the described effect occurs only in the case of modulated illumination with a high modulation frequency.

By way of example, the detector can be designed to bring about a modulation of the illumination of the object and/or at least one sensor region of the detector, such as at least one sensor region of the at least one longitudinal optical sensor, with a frequency of 0.05 Hz to 1 MHz, such as 0.1 Hz to 10 kHz. As outlined above, for this purpose, the detector may comprise at least one modulation device, which may be integrated into the at least one optional illumination source and/or may be independent from the illumination source. Thus, at least one illumination source might, by itself, be adapted to generate the above-mentioned modulation of the illumination, and/or at least one independent modulation device may be present, such as at least one chopper and/or at least one device having a modulated transmissibility, such as at least one electro-optical device and/or at least one acousto-optical device.

The above-mentioned trap states can be present for example with a density of 10^{-5} to 10^{-1} , relative to the n-semiconducting material and/or the p-semiconducting material and/or the dye.

The energy differences ΔE with respect to the conduction band and with respect to the valence band can be in particular 0.05-0.3 eV.

5 The detector has, as described above, at least one evaluation device. In particular, the at least one evaluation device can also be designed to completely or partly control or drive the detector, for example by the evaluation device being designed to control one or a plurality of modulation devices of the detector and/or to control at least one illumination source of the detector. The evaluation device can be designed, in particular, to carry out at least one measurement cycle in which one or a plurality of sensor signals, such as a plurality of longitudinal sensor signals, are
10 picked up, for example a plurality of sensor signals of successively at different modulation frequencies of the illumination.

However, unlike in conventional semiconductor devices in which, e.g. the absorption of incident light may occur in a p-type conductor, the absorption of incident light in the present detector
15 may be spatially separated from the movement of the charge carriers in dye sensitized solar cells (DSCs), where incident light may cause the light-absorbing organic dye to switch into an excited state such as Frenkel excitons, i.e. excited, strongly bound electron-hole pairs. As long as the energy levels of both the p-type conductor and the n-type conductor are well-matched to the energy states of the excited light-absorbing organic dye, the excitons may be separated
20 and, thus, the electrons and the holes may travel through the n-type and the p-type conductor, respectively, to the appropriate contact electrodes. Hereby, the moving charge carriers may be majority charge carriers, i.e. in the n-type conductor electrons, in the p-type conductor holes are traveling. Since the light-absorbing organic dye itself is a non-conducting substance, an effective charge transport may depend on an extent to which molecules of the light-absorbing
25 organic dye are in close contact with both the p-type conductor and the n-type conductor. For potential details of DSCs, reference may be made e.g. to U. Bach, M. Grätzel, D. Lupo, P. Comte, J. E. Moser, F. Weissörtel, J. Salbeck, and H. Spreitzer. "Solid-state dye-sensitized mesoporous TiO₂ solar cells with high proton-to-electron conversion efficiencies". *Nature*, Vol. 395, no. 6702, pp. 583-585, 1998.

30 As described above, when light falls on the cell, it may be absorbed by the light-absorbing organic dye and an exciton may be created. If the energy of the absorbed photons is greater than an energy gap between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) of the light-absorbing organic dye, an electron of the
35 HOMO may be raised to the LUMO of the photoexcited dye and charge separation may take place at the boundary between the dye and the semiconductor which nanoporous titanium dioxide. From there, the electron may travel within femtoseconds to picoseconds further into the conduction band of nanoporous titanium dioxide. Preferably, the energy level of the excited state is matched to the lower limit of the conduction band of the titanium dioxide in order to
40 minimize energy losses during electron transition and the LUMO level should extend sufficiently beyond the lower limit of the conduction band of the titanium dioxide. The oxidation potential of the hole conductor should extend over the HOMO level of the dye allowing it to transport away

the holes of the excited dye. If a load is connected in an external circuit, a current may flow across the titanium dioxide and the anode. The reduced dye may be regenerated through electron donation by the organic p-type conductor to the dye, which may prevent recombination of the electrons from the conduction band of the titanium dioxide with the oxidised dye. The p-type conductor, in turn, may be regenerated through the counter-electrode, which may ensure a constant conversion of energy from incident light into electrical energy without requiring a permanent chemical change.

The evaluation device is designed, as described above, to generate at least one item of information on a transversal position of the object by evaluating the transversal sensor signal and to generate at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal. Said position of the object can be static or may even comprise at least one movement of the object, for example a relative movement between the detector or parts thereof and the object or parts thereof. In this case, a relative movement can generally comprise at least one linear movement and/or at least one rotational movement. Items of movement information can for example also be obtained by comparison of at least two items of information picked up at different times, such that for example at least one item of location information can also comprise at least one item of velocity information and/or at least one item of acceleration information, for example at least one item of information about at least one relative velocity between the object or parts thereof and the detector or parts thereof. In particular, the at least one item of location information can generally be selected from: an item of information about a distance between the object or parts thereof and the detector or parts thereof, in particular an optical path length; an item of information about a distance or an optical distance between the object or parts thereof and the optional transfer device or parts thereof; an item of information about a positioning of the object or parts thereof relative to the detector or parts thereof; an item of information about an orientation of the object and/or parts thereof relative to the detector or parts thereof; an item of information about a relative movement between the object or parts thereof and the detector or parts thereof; an item of information about a two-dimensional or three-dimensional spatial configuration of the object or of parts thereof, in particular a geometry or form of the object. Generally, the at least one item of location information can therefore be selected for example from the group consisting of: an item of information about at least one location of the object or at least one part thereof; information about at least one orientation of the object or a part thereof; an item of information about a geometry or form of the object or of a part thereof, an item of information about a velocity of the object or of a part thereof, an item of information about an acceleration of the object or of a part thereof, an item of information about a presence or absence of the object or of a part thereof in a visual range of the detector.

The at least one item of location information can be specified for example in at least one coordinate system, for example a coordinate system in which the detector or parts thereof rest. Alternatively or additionally, the location information can also simply comprise for example a

distance between the detector or parts thereof and the object or parts thereof. Combinations of the possibilities mentioned are also conceivable.

As outlined above, the detector may comprise at least one illumination source. The illumination source can be embodied in various ways. Thus, the illumination source can be for example part of the detector in a detector housing. Alternatively or additionally, however, the at least one illumination source can also be arranged outside a detector housing, for example as a separate light source. The illumination source can be arranged separately from the object and illuminate the object from a distance. Alternatively or additionally, the illumination source can also be connected to the object or even be part of the object, such that, by way of example, the electromagnetic radiation emerging from the object can also be generated directly by the illumination source. By way of example, at least one illumination source can be arranged on and/or in the object and directly generate the electromagnetic radiation by means of which the sensor region is illuminated. By way of example, at least one infrared emitter and/or at least one emitter for visible light and/or at least one emitter for ultraviolet light can be arranged on the object. By way of example, at least one light emitting diode and/or at least one laser diode can be arranged on and/or in the object. The illumination source can comprise in particular one or a plurality of the following illumination sources: a laser, in particular a laser diode, although in principle, alternatively or additionally, other types of lasers can also be used; a light emitting diode; an incandescent lamp; an organic light source, in particular an organic light emitting diode. Alternatively or additionally, other illumination sources can also be used. It is particularly preferred if the illumination source is designed to generate one or more light beams having a Gaussian beam profile, as is at least approximately the case for example in many lasers. However, other embodiments are also possible, in principle.

As outlined above, a further aspect of the present invention proposes a human-machine interface for exchanging at least one item of information between a user and a machine. A human-machine interface should generally be understood to mean a device by means of which such information can be exchanged. The machine can comprise in particular a data processing device. The at least one item of information can generally comprise for example data and/or control commands. Thus, the human-machine interface can be designed in particular for the inputting of control commands by the user.

The human-machine interface has at least one detector in accordance with one or a plurality of the embodiments described above. The human-machine interface is designed to generate at least one item of geometrical information of the user by means of the detector wherein the human-machine interface is designed to assign to the geometrical information at least one item of information, in particular at least one control command. By way of example, said at least one item of geometrical information can be or comprise an item of location information and/or position information and/or orientation information about a body and/or at least one body part of the user, for example an item of location information about a hand posture and/or a posture of some other body part of the user.

In this case, the term user should be interpreted broadly and can for example also encompass one or a plurality of articles directly influenced by the user. Thus, the user can for example also wear one or a plurality of gloves and/or other garments, wherein the geometrical information is at least one item of geometrical information of this at least one garment. By way of example, such garments can be embodied as reflective to a primary radiation emerging from at least one illumination source, for example by the use of one or a plurality of reflectors. Once again alternatively or additionally, the user can for example spatially move one or a plurality of articles whose geometrical information can be detected, which is likewise also intended to be subsumable under generation of at least one item of geometrical information of the user. By way of example, the user can move at least one reflective rod and/or some other type of article, for example by means of said user's hand.

The at least one item of geometrical information can be static, that is to say can for example once again comprise a snapshot, but can also for example once again comprise a series of sequential items of geometrical information and/or at least one movement. By way of example, at least two items of geometrical information picked up at different times can be compared, such that, by way of example, the at least one item of geometrical information can also comprise at least one item of information about a velocity and/or an acceleration of a movement. Accordingly, the at least one item of geometrical information can for example comprise at least one item of information about at least one body posture and/or about at least one movement of the user.

The human-machine interface is designed to assign to the geometrical information at least one item of information, in particular at least one control command. As explained above, the term information should in this case be interpreted broadly and can comprise for example data and/or control commands. By way of example, the human-machine interface can be designed to assign the at least one item of information to the at least one item of geometrical information, for example by means of a corresponding assignment algorithm and/or a stored assignment specification. By way of example, a unique assignment between a set of items of geometrical information and corresponding items of information can be stored. In this way, for example by means of a corresponding body posture and/or movement of the user, an inputting of at least one item of information can be effected.

Such human-machine interfaces can generally be used in the machine control or else for example in virtual reality. By way of example, industrial controllers, manufacturing controllers, machine controllers in general, robot controllers, vehicle controllers or similar controllers can be made possible by means of the human-machine interface having the one or the plurality of detectors. However, the use of such a human-machine interface in consumer electronics is particularly preferred.

Accordingly, as outlined above, a further aspect of the present invention proposes an entertainment device for carrying out at least one entertainment function, in particular a game. The entertainment function can comprise in particular at least one game function. By way of example, one or a plurality of games can be stored which can be influencable by a user, who in this context is also called a player hereinafter. By way of example, the entertainment device can comprise at least one display device, for example at least one screen and/or at least one projector and/or at least one set of display spectacles.

The entertainment device furthermore comprises at least one human-machine interface in accordance with one or more of the embodiments described above. The entertainment device is designed to enable at least one item of information of a player to be input by means of the human-machine interface. By way of example, the player, as described above, can adopt or alter one or a plurality of body postures for this purpose. This includes the possibility of the player for example using corresponding articles for this purpose, for example garments such as e.g. gloves, for example garments which are equipped with one or a plurality of reflectors for reflecting the electromagnetic radiation of the detector. The at least one item of information can comprise for example, as explained above, one or a plurality of control commands. By way of example, in this way, changes in direction can be performed, inputs can be confirmed, a selection can be made from a menu, specific game options can be initiated, movements can be influenced in a virtual space or similar instances of influencing or altering the entertainment function can be performed.

The above-described detector, the method, the human-machine interface and the entertainment device and also the proposed uses have considerable advantages over the prior art. Thus, generally, a simple and, still, efficient detector for determining a position of at least one object in space may be provided. Therein, as an example, three-dimensional coordinates of an object or part of an object may be determined in a fast and efficient way. Specifically the combination of the at least one transversal optical sensor and the at least one longitudinal optical sensor, which each may be designed in a cost-efficient way, may lead to a compact, cost-efficient and, still, highly precise device. Both the at least one transversal optical sensor and the at least one longitudinal optical sensor preferably may fully or partially be designed as organic photovoltaic devices, such as by using dye-sensitized solar cells for each of these optical sensors, preferably sDSCs.

As compared to devices known in the art, which of them are based on complex triangulation methods, the detector as proposed provides a high degree of simplicity, specifically with regard to an optical setup of the detector. Thus, in principle, a simple combination of one, two or more sDSCs, preferably in combination with a suited transfer device, specifically a suited lens, and in conjunction with an appropriate evaluation device, is sufficient for high precision position detection.

This high degree of simplicity, in combination with the possibility of high precision measurements, is specifically suited for machine control, such as in human-machine interfaces and, more preferably, in gaming. Thus, cost-efficient entertainment devices may be provided which may be used for a large number of gaming purposes.

5

Thus, as for the optical detectors and devices disclosed in WO 2012/110924 A1 or in US provisional applications 61/739,173, filed on December 19, 2012, and 61/749,964, filed on January 8, 2013, the optical detector, the detector system, the human-machine interface, the entertainment device, the tracking system or the camera according to the present invention (in
10 the following simply referred to as "the devices according to the present invention" or "Fip-devices") may be used for a plurality of application purposes, such as one or more of the purposes disclosed in further detail in the following.

Thus, firstly, Fip-devices may be used in mobile phones, tablet computers, laptops, smart
15 panels or other stationary or mobile computer or communication applications. Thus, Fip-devices may be combined with at least one active light source, such as a light source emitting light in the visible range or infrared spectral range, in order to enhance performance. Thus, as an example, Fip-devices may be used as cameras and/or sensors, such as in combination with mobile software for scanning environment, objects and living beings. Fip-devices may even be
20 combined with 2D cameras, such as conventional cameras, in order to increase imaging effects. Fip-devices may further be used for surveillance and/or for recording purposes or as input devices to control mobile devices, especially in combination with gesture recognition. Thus, specifically, Fip-devices acting as human-machine interfaces, also referred to as FiP input devices, may be used in mobile applications, such as for controlling other electronic devices or
25 components via the mobile device, such as the mobile phone. As an example, the mobile application including at least one Fip-device may be used for controlling a television set, a game console, a music player or music device or other entertainment devices.

Further, Fip-devices may be used in webcams or other peripheral devices for computing
30 applications. Thus, as an example, Fip-devices may be used in combination with software for imaging, recording, surveillance, scanning or motion detection. As outlined in the context of the human-machine interface and/or the entertainment device, Fip-devices are particularly useful for giving commands by facial expressions and/or body expressions. Fip-devices can be combined with other input generating devices like e.g. mouse, keyboard, touchpad, etc. Further,
35 Fip-devices may be used in applications for gaming, such as by using a webcam. Further, Fip-devices may be used in virtual training applications and/or video conferences.

Further, Fip-devices may be used in mobile audio devices, television devices and gaming
40 devices, as partially explained above. Specifically, Fip-devices may be used as controls or control devices for electronic devices, entertainment devices or the like. Further, Fip-devices may be used for eye detection or eye tracking, such as in 2D- and 3D-display techniques, especially with transparent displays for augmented reality applications.

Further, Fip-devices may be used in or as digital cameras such as DSC cameras and/or in or as reflex cameras such as SLR cameras. For these applications, reference may be made to the use of Fip-devices in mobile applications such as mobile phones, as disclosed above.

5

Further, Fip-devices may be used for security and surveillance applications. Specifically, Fip-devices may be used for optical encryption. Fip-based detection can be combined with other detection devices to complement wavelengths, such as with IR, x-ray, UV-VIS, radar or ultrasound detectors. Fip-devices may further be combined with an active infrared light source to allow detection in low light surroundings. Fip-devices such as FIP-based sensors are generally advantageous as compared to active detector systems, specifically since Fip-devices avoid actively sending signals which may be detected by third parties, as is the case e.g. in radar applications, ultrasound applications, LIDAR or similar active detector device is. Thus, generally, Fip-devices may be used for an unrecognized and undetectable tracking of moving objects. Additionally, Fip-devices generally are less prone to manipulations and irritations as compared to conventional devices.

Further, given the ease and accuracy of 3D detection by using Fip-devices, Fip-devices generally may be used for facial, body and person recognition and identification. Therein, Fip-devices may be combined with other detection means for identification or personalization purposes such as passwords, finger prints, iris detection, voice recognition or other means. Thus, generally, Fip-devices may be used in security devices and other personalized applications.

Further, Fip-devices may be used as 3D-Barcode readers for product identification.

In addition to the security and surveillance applications mentioned above, Fip-devices generally can be used for surveillance and monitoring of spaces and areas. Thus, Fip-devices may be used for surveying and monitoring spaces and areas and, as an example, for triggering or executing alarms in case prohibited areas are violated. Thus, generally, Fip-devices may be used for surveillance purposes in building surveillance or museums, optionally in combination with other types of sensors, such as in combination with motion or heat sensors, in combination with image intensifiers or image enhancement devices and/or photomultipliers.

Further, Fip-devices may advantageously be applied in camera applications such as video and camcorder applications. Thus, Fip-devices may be used for motion capture and 3D-movie recording. Therein, Fip-devices generally provide a large number of advantages over conventional optical devices. Thus, Fip-devices generally require a lower complexity with regard to optical components. Thus, as an example, the number of lenses may be reduced as compared to conventional optical devices, such as by providing Fip-devices having one lens only. Due to the reduced complexity, very compact devices are possible, such as for mobile use. Conventional optical systems having two or more lenses with high quality generally are

voluminous, such as due to the general need for voluminous beam-splitters. Further, Fip-devices generally may be used for focus/autofocus devices, such as autofocus cameras. Further, Fip-devices may also be used in optical microscopy, especially in confocal microscopy.

- 5 Further, Fip-devices generally are applicable in the technical field of automotive technology and transport technology. Thus, as an example, Fip-devices may be used as distance and surveillance sensors, such as for adaptive cruise control, emergency brake assist, lane departure warning, surround view, blind spot detection, rear cross traffic alert, and other automotive and traffic applications. Therein, Fip-devices may be used as standalone devices or
- 10 in combination with other sensor devices, such as in combination with radar and/or ultrasonic devices. Specifically, Fip-devices may be used for autonomous driving and safety issues. Further, in these applications, Fip-devices may be used in combination with infrared sensors, radar sensors, which are sonic sensors, two-dimensional cameras or other types of sensors. Advantage, in these applications, the generally passive nature of typical Fip-devices is
- 15 advantageous. Thus, since Fip-devices generally do not require emitting signals, the risk of interference of active sensor signals with other signal sources may be avoided. Fip-devices specifically may be used in combination with recognition software, such as standard image recognition software. Thus, signals and data as provide by Fip-devices typically are readily processable and, therefore, generally require lower calculation power than established
- 20 stereovision systems such as LIDAR. Given the low space demand, Fip-devices such as cameras using the FiP-effect may be placed at virtually any place in a vehicle, such as on a window screen, on a front hood, on bumpers, on lights, on mirrors or other places the like. Various detectors based on the FiP-effect can be combined, such as in order to allow autonomously driving vehicles or in order to increase the performance of active safety concepts.
- 25 Thus, various FiP-based sensors may be combined with other Fip-based sensors and/or conventional sensors, such as in the windows like rear window, side window or front window, on the bumpers or on the lights.

- A combination of a FiP-sensor with one or more rain detection sensors is also possible. This is
- 30 due to the fact that Fip-devices generally are advantageous over conventional sensor techniques such as radar, specifically during heavy rain. A combination of at least one Fip-device with at least one conventional sensing technique such as radar may allow for a software to pick the right combination of signals according to the weather conditions.

- 35 Further, Fip-devices generally may be used as break assist and/or parking assist and/or for speed measurements. Speed measurements can be integrated in the vehicle or may be used outside the vehicle, such as in order to measure the speed of other cars in traffic control. Further, Fip-devices may be used for detecting free parking spaces in parking lots.

- 40 Further, Fip-devices may be used is the fields of medical systems and sports. Thus, in the field of medical technology, surgery robotics, e.g. for use in endoscopes, may be named, since, as outlined above, Fip-devices may require a low volume only and may be integrated into other

devices. Specifically, Fip-devices having one lens, at most, may be used for capturing 3D information in medical devices such as in endoscopes. Further, Fip-devices may be combined with an appropriate monitoring software, in order to enable tracking and analysis of movements. These applications are specifically valuable e.g. in medical treatments and long-distance diagnosis and tele-medicine.

Further, Fip-devices may be applied in the field of sports and exercising, such as for training, remote instructions or competition purposes. Specifically, Fip-devices may be applied in the field of dancing, aerobic, football, soccer, basketball, baseball, cricket, hockey, track and field, swimming, polo, handball, volleyball, rugby, sumo, judo, fencing, boxing etc. Fip-devices can be used to detect the position of a ball, a bat, a sword, motions, etc., both in sports and in games, such as to monitor the game, support the referee or for judgment, specifically automatic judgment, of specific situations in sports, such as for judging whether a point or a goal actually was made.

Fip devices may further be used to support a practice of musical instruments, in particular remote lessons, for example lessons of string instruments, such as fiddles, violins, violas, celli, basses, harps, guitars, banjos, or ukuleles, keyboard instruments, such as pianos, organs, keyboards, harpsichords, harmoniums, or accordions, and/or percussion instruments, such as drums, timpani, marimbas, xylophones, vibraphones, bongos, congas, timbales, djembes or tablas.

Fip-devices further may be used in rehabilitation and physiotherapy, in order to encourage training and/or in order to survey and correct movements. Therein, the Fip-devices may also be applied for distance diagnostics.

Further, Fip-devices may be applied in the field of machine vision. Thus, one or more Fip-devices may be used e.g. as a passive controlling unit for autonomous driving and or working of robots. In combination with moving robots, Fip-devices may allow for autonomous movement and/or autonomous detection of failures in parts. Fip-devices may also be used for manufacturing and safety surveillance, such as in order to avoid accidents including but not limited to collisions between robots, production parts and living beings. Given the passive nature of Fip-devices, Fip-devices may be advantageous over active devices and/or may be used complementary to existing solutions like radar, ultrasound, 2D cameras, IR detection etc. One particular advantage of Fip-devices is the low likelihood of signal interference. Therefore multiple sensors can work at the same time in the same environment, without the risk of signal interference. Thus, Fip-devices generally may be useful in highly automated production environments like e.g. but not limited to automotive, mining, steel, etc. Fip-devices can also be used for quality control in production, e.g. in combination with other sensors like 2-D imaging, radar, ultrasound, IR etc., such as for quality control or other purposes. Further, Fip-devices may be used for assessment of surface quality, such as for surveying the surface evenness of a

product or the adherence to specified dimensions, from the range of micrometers to the range of meters. Other quality control applications are feasible.

Further, Fip-devices may be used in the polls, airplanes, ships, spacecrafts and other traffic applications. Thus, besides the applications mentioned above in the context of traffic applications, passive tracking systems for aircrafts, vehicles and the like may be named. Detection devices based on the FiP-effect for monitoring the speed and/or the direction of moving objects are feasible. Specifically, the tracking of fast moving objects on land, sea and in the air including space may be named. The at least one Fip-detector specifically may be mounted on a still-standing and/or on a moving device. An output signal of the at least one Fip-device can be combined e.g. with a guiding mechanism for autonomous or guided movement of another object. Thus, applications for avoiding collisions or for enabling collisions between the tracked and the steered object are feasible. Fip-devices generally are useful and advantageous due to the low calculation power required, the instant response and due to the passive nature of the detection system which generally is more difficult to detect and to disturb as compared to active systems, like e.g. radar. Fip-devices are particularly useful but not limited to e.g. speed control and air traffic control devices.

Fip-devices generally may be used in passive applications. Passive applications include guidance for ships in harbors or in dangerous areas, and for aircrafts at landing or starting. Wherein, fixed, known active targets may be used for precise guidance. The same can be used for vehicles driving in dangerous but well defined routes, such as mining vehicles.

Further, as outlined above, Fip-devices may be used in the field of gaming. Thus, Fip-devices can be passive for use with multiple objects of the same or of different size, color, shape, etc., such as for movement detection in combination with software that incorporates the movement into its content. In particular, applications are feasible in implementing movements into graphical output. Further, applications of Fip-devices for giving commands are feasible, such as by using one or more Fip-devices for gesture or facial recognition. Fip-devices may be combined with an active system in order to work under e.g. low light conditions or in other situations in which enhancement of the surrounding conditions is required. Additionally or alternatively, a combination of one or more Fip-devices with one or more IR or VIS light sources is possible, such as with a detection device based on the FiP effect. A combination of a FiP-based detector with special devices is also possible, which can be distinguished easily by the system and its software, e.g. and not limited to, a special color, shape, relative position to other devices, speed of movement, light, frequency used to modulate light sources on the device, surface properties, material used, reflection properties, transparency degree, absorption characteristics, etc. The device can, amongst other possibilities, resemble a stick, a racquet, a club, a gun, a knife, a wheel, a ring, a steering wheel, a bottle, a ball, a glass, a vase, a spoon, a fork, a cube, a dice, a figure, a puppet, a teddy, a beaker, a pedal, a switch, a glove, jewelry, a musical instrument or an auxiliary device for playing a musical instrument, such as a plectrum, a drumstick or the like. Other options are feasible.

Further, Fip-devices generally may be used in the field of building, construction and cartography. Thus, generally, FiP-based devices may be used in order to measure and/or monitor environmental areas, e.g. country side or buildings. Therein, one or more Fip-devices may be combined with other methods and devices or can be used solely in order to monitor progress and accuracy of building projects, changing objects, houses, etc. FiP-devices can be used for generating three-dimensional models of scanned environments, in order to construct maps of rooms, streets, houses, communities or landscapes, both from ground or from air. Potential fields of application may be construction, cartography, real estate management, land surveying or the like.

FiP-devices may be used within an interconnecting network of home appliances such as CHAIN (Cedec Home Appliances Interoperating Network) to interconnect, automate, and control basic appliance-related services in a home, e.g. energy or load management, remote diagnostics, pet related appliances, child related appliances, child surveillance, appliances related surveillance, support or service to elderly or ill persons, home security and/or surveillance, remote control of appliance operation, and automatic maintenance support.

FiP devices may further be used in agriculture, for example to detect and sort out vermin, weeds, and/or infected crop plants, fully or in parts, wherein crop plants may be infected by fungus or insects. Further, for harvesting crops, FiP detectors may be used to detect animals, such as deer, which may otherwise be harmed by harvesting devices.

FiP-based devices can further be used for scanning of objects, such as in combination with CAD or similar software, such as for additive manufacturing and/or 3D printing. Therein, use may be made of the high dimensional accuracy of Fip-devices, e.g. in x-, y- or z- direction or in any arbitrary combination of these directions, such as simultaneously. Further, Fip-devices may be used in inspections and maintenance, such as pipeline inspection gauges.

As outlined above, Fip-devices may further be used in manufacturing, quality control or identification applications, such as in product identification or size identification (such as for finding an optimal place or package, for reducing waste etc.). Further, Fip-devices may be used in logistics applications. Thus, Fip-devices may be used for optimized loading or packing containers or vehicles. Further, Fip-devices may be used for monitoring or controlling of surface damages in the field of manufacturing, for monitoring or controlling rental objects such as rental vehicles, and/or for insurance applications, such as for assessment of damages. Further, Fip-devices may be used for identifying a size of material, object or tools, such as for optimal material handling, especially in combination with robots. Further, Fip-devices may be used for process control in production, e.g. for observing filling level of tanks. Further, Fip-devices may be used for maintenance of production assets like, but not limited to, tanks, pipes, reactors, tools etc. Further, Fip-devices may be used for analyzing 3D-quality marks. Further, Fip-devices may be used in manufacturing tailor-made goods such as tooth inlays, dental braces,

prosthesis, clothes or the like. Fip-devices may also be combined with one or more 3D-printers for rapid prototyping, 3D-copying or the like. Further, Fip-devices may be used for detecting the shape of one or more articles, such as for anti-product piracy and for anti-counterfeiting purposes.

5

As outlined above, preferably, the at least one transversal optical sensor and/or the at least one longitudinal optical sensor both may comprise at least one organic semiconductor detector, particularly preferably at least one dye solar cell, DSC or sDSC. In particular, the transversal optical sensor and/or the longitudinal optical sensor each may comprise at least one first
10 electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material and at least one second electrode, preferably in the stated order. The stated elements can be present as layers in a layer construction, for example. The layer construction can be applied for example to a substrate, preferably a transparent substrate, for example a glass substrate.

15

Preferred embodiments of the above-mentioned elements of the preferred optical sensor are described below by way of example, wherein these embodiments can be used in any desired combination. However, numerous other configurations are also possible, in principle, wherein reference can be made for example to WO 2012/110924 A1, US 2007/0176165 A1,
20 US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1 and WO 2009/013282 A1 cited above.

As outlined above, the at least one transversal optical sensor may be designed as a dye-sensitized solar cell (DSC), preferably a solid dye-sensitized solar cell (sDSC). Similarly, the at least one longitudinal optical sensor may be designed as at least one dye-sensitized solar cell
25 (DSC) or may comprise at least one dye-sensitized solar cell (DSC), preferably a solid dye-sensitized solar cell (sDSC). More preferably, the at least one longitudinal optical sensor comprises a stack of DSCs, preferably a stack of sDSCs. Preferred components of the DSCs or sDSCs will be disclosed in the following. However, it shall be understood that other embodiments are feasible.

30

First electrode and n-semiconductive metal oxide

Generally, for preferred embodiments of the first electrode and the n-semiconductive metal oxide, which may be used in a layer setup of the transversal optical sensor and/or the
35 longitudinal optical sensor, reference may be made to WO 2012/110924 A1. The n-semiconductive metal oxide used in the dye solar cell of the transversal optical sensor and/or the longitudinal optical sensor may be a single metal oxide or a mixture of different oxides. It is also possible to use mixed oxides. The n-semiconductive metal oxide may especially be porous and/or be used in the form of a nanoparticulate oxide, nanoparticles in this context being
40 understood to mean particles which have an average particle size of less than 0.1 micrometer. A nanoparticulate oxide is typically applied to a conductive substrate (i.e. a carrier with a

conductive layer as the first electrode) by a sintering process as a thin porous film with large surface area.

Preferably, the at least one transversal optical sensor uses at least one transparent substrate.

- 5 Similarly, preferably, the at least one longitudinal optical sensor uses at least one transparent substrate. In case a plurality of longitudinal optical sensors is used, such as a stack of longitudinal optical sensors, preferably, at least one of these longitudinal optical sensors uses a transparent substrate. Thus, as an example, all longitudinal optical sensors but the last longitudinal optical sensor facing away from the object, each may use a transparent substrate.
- 10 The last longitudinal optical sensor may either use a transparent or an intransparent substrate.

Similarly, the at least one transversal optical sensor uses at least one transparent first electrode. Further, the at least one longitudinal optical sensor may use at least one transparent first electrode. In case a plurality of longitudinal optical sensors is used, such as a stack of longitudinal optical sensors, preferably, at least one of these longitudinal optical sensors uses a transparent first electrode. Thus, as an example, all longitudinal optical sensors but the last longitudinal optical sensor facing away from the object each may use a transparent first electrode. The last longitudinal optical sensor may either use a transparent or an intransparent first electrode.

- 20 The substrate may be rigid or else flexible. Suitable substrates (also referred to hereinafter as carriers) are, as well as metal foils, in particular plastic sheets or films and especially glass sheets or glass films. Particularly suitable electrode materials, especially for the first electrode according to the above-described, preferred structure, are conductive materials, for example transparent conductive oxides (TCOs), for example fluorine- and/or indium-doped tin oxide (FTO or ITO) and/or aluminum-doped zinc oxide (AZO), carbon nanotubes or metal films.
- 25 Alternatively or additionally, it would, however, also be possible to use thin metal films which still have a sufficient transparency. In case an intransparent first electrode is desired and used, thick metal films may be used.

- 30 The substrate can be covered or coated with these conductive materials. Since generally, only a single substrate is required in the structure proposed, the formation of flexible cells is also possible. This enables a multitude of end uses which would be achievable only with difficulty, if at all, with rigid substrates, for example use in bank cards, garments, etc.

- 35 The first electrode, especially the TCO layer, may additionally be covered or coated with a solid metal oxide buffer layer (for example of thickness 10 to 200 nm), in order to prevent direct contact of the p-type semiconductor with the TCO layer (see Peng *et al.*, Coord. Chem. Rev. 248, 1479 (2004)). The inventive use of solid p-semiconducting electrolytes, in the case of which contact of the electrolyte with the first electrode is greatly reduced compared to liquid or gel-form electrolytes, however, makes this buffer layer unnecessary in many cases, such that it is possible in many cases to dispense with this layer, which also has a current-limiting effect
- 40

and can also worsen the contact of the n-semiconducting metal oxide with the first electrode. This enhances the efficiency of the components. On the other hand, such a buffer layer can in turn be utilized in a controlled manner in order to match the current component of the dye solar cell to the current component of the organic solar cell. In addition, in the case of cells in which the buffer layer has been dispensed with, especially in solid cells, problems frequently occur with unwanted recombinations of charge carriers. In this respect, buffer layers are advantageous in many cases specifically in solid cells.

As is well known, thin layers or films of metal oxides are generally inexpensive solid semiconductor materials (n-type semiconductors), but the absorption thereof, due to large band gaps, is typically not within the visible region of the electromagnetic spectrum, but rather usually in the ultraviolet spectral region. For use in solar cells, the metal oxides therefore generally, as is the case in the dye solar cells, have to be combined with a dye as a photosensitizer, which absorbs in the wavelength range of sunlight, i.e. at 300 to 2000 nm, and, in the electronically excited state, injects electrons into the conduction band of the semiconductor. With the aid of a solid p-type semiconductor used additionally in the cell as an electrolyte, which is in turn reduced at the counter electrode, electrons can be recycled to the sensitizer, such that it is regenerated.

Of particular interest for use in organic solar cells are semiconductors zinc oxide, tin dioxide, titanium dioxide or mixtures of these metal oxides. The metal oxides can be used in the form of nanocrystalline porous layers. These layers have a large surface area which is coated with the dye as a sensitizer, such that a high absorption of sunlight is achieved. Metal oxide layers which are structured, for example nanorods, give advantages such as higher electron mobilities or improved pore filling by the dye.

The metal oxide semiconductors can be used alone or in the form of mixtures. It is also possible to coat a metal oxide with one or more other metal oxides. In addition, the metal oxides may also be applied as a coating to another semiconductor, for example GaP, ZnP or ZnS.

Particularly preferred semiconductors are zinc oxide and titanium dioxide in the anatase polymorph, which is preferably used in nanocrystalline form.

In addition, the sensitizers can advantageously be combined with all n-type semiconductors which typically find use in these solar cells. Preferred examples include metal oxides used in ceramics, such as titanium dioxide, zinc oxide, tin(IV) oxide, tungsten(VI) oxide, tantalum(V) oxide, niobium(V) oxide, cesium oxide, strontium titanate, zinc stannate, complex oxides of the perovskite type, for example barium titanate, and binary and ternary iron oxides, which may also be present in nanocrystalline or amorphous form.

Due to the strong absorption that customary organic dyes and phthalocyanines and porphyrins have, even thin layers or films of the n-semiconducting metal oxide are sufficient to absorb the

required amount of dye. Thin metal oxide films in turn have the advantage that the probability of unwanted recombination processes falls and that the internal resistance of the dye subcell is reduced. For the n-semiconducting metal oxide, it is possible with preference to use layer thicknesses of 100 nm up to 20 micrometers, more preferably in the range between 500 nm and approx. 3 micrometers.

Dye

In the context of the present invention, as usual in particular for DSCs, the terms "dye", "sensitizer dye" and "sensitizer" are used essentially synonymously without any restriction of possible configurations. Numerous dyes which are usable in the context of the present invention are known from the prior art, and so, for possible material examples, reference may also be made to the above description of the prior art regarding dye solar cells. As a preferred example, one or more of the dyes disclosed in WO 2012/110924 A1 may be used.

Additionally or alternatively, one or more quinolinium dyes with fluorinated counter anion may be used in the detector according to the present invention, such as one or more of the dyes as disclosed in WO 2013/144177 A1. Specifically, one or more of the dyes disclosed in the following may be used in the at least one longitudinal optical sensor and/or in the at least one transversal optical sensor. Details of these dyes and details of the disclosure of these unpublished applications will be given below. Specifically, dye D-5, which will be described below in more detail, may be used. However, one or more other dyes may be used in addition or alternatively.

All dyes listed and claimed may in principle also be present as pigments. Dye-sensitized solar cells based on titanium dioxide as a semiconductor material are described, for example, in US 4 927 721 A, Nature 353, p. 737-740 (1991) and US 5 350 644 A, and also Nature 395, p. 583-585 (1998) and EP 1 176 646 A1. The dyes described in these documents can in principle also be used advantageously in the context of the present invention. These dye solar cells preferably comprise monomolecular films of transition metal complexes, especially ruthenium complexes, which are bonded to the titanium dioxide layer via acid groups as sensitizers.

Dyes for use in dye-sensitized solar cells which may comprise ruthenium complexes have been rather of academic interest so far, particularly due to the high costs of ruthenium. However, a dye-sensitized solar cell which may be used in the detector according to the present invention would only require such a small amount of ruthenium that the cost argument may easily be overruled by its attractive features for use within the present method for determining a position of at least one object, particularly in a case where at least one light beam which travels from the object might involve a spectral range which may at least partially include a part of the infrared (IR) region, i.e. a part of the electromagnetic spectrum ranging from approximately 750 nm to 1000 μm , preferentially a part thereof generally denoted as near infrared (NIR) region, which is usually considered to range from approximately 750 nm to 1.5 μm . Examples of known

ruthenium complexes which might be suitable for an application within the detector according to the present invention are:

5

Another example may be found in T. Kinoshita, J.T. Dy, S. Uchida, T. Kubo, and H. Segawa, *Wideband dye-sensitized solar cells employing a phosphine-coordinated ruthenium sensitizer*, Nature Photonics, 7, 535-539 (2013), wherein a phosphine-coordinated ruthenium complex is described, which exhibits a strong absorption in the NIR, particularly within the range from 750 nm to 950 nm, which may thus, yield a dye-sensitized solar cell with a promising efficiency:

10

15 Owing to weak absorption properties of most known dyes within the IR region, including the NIR region, dyes comprising ruthenium complexes may, thus, be able to extend the scope of the

detector according to the present invention into the IR region, in particular into the NIR region, e.g. as being used as active depth sensors, particularly in applications related to computer vision, wherein IR light may play an important role, as described elsewhere in this application.

5 Many sensitizers which have been proposed include metal-free organic dyes, which are likewise also usable in the context of the present invention. High efficiencies of more than 4%, especially in solid dye solar cells, can be achieved, for example, with indoline dyes (see, for example, Schmidt-Mende *et al.*, Adv. Mater. 2005, 17, 813). US-A-6 359 211 describes the use, also implementable in the context of the present invention, of cyanine, oxazine, thiazine and acridine
10 dyes which have carboxyl groups bonded via an alkylene radical for fixing to the titanium dioxide semiconductor.

Organic dyes now achieve efficiencies of almost 12.1% in liquid cells (see, for example, P. Wang *et al.*, ACS. Nano 2010). Pyridinium-containing dyes have also been reported, can be
15 used in the context of the present invention and exhibit promising efficiencies.

Particularly preferred sensitizer dyes in the dye solar cell proposed are the perylene derivatives, terrylene derivatives and quaterrylene derivatives described in DE 10 2005 053 995 A1 or WO 2007/054470 A1. The use of these dyes, which is also possible in the context of the
20 present invention, leads to photovoltaic elements with high efficiencies and simultaneously high stabilities.

The rylenes exhibit strong absorption in the wavelength range of sunlight and can, depending on the length of the conjugated system, cover a range from about 400 nm (perylene derivatives I from DE 10 2005 053 995 A1) up to about 900 nm (quaterrylene derivatives I from
25 DE 10 2005 053 995 A1). Rylene derivatives I based on terrylene absorb, according to the composition thereof, in the solid state adsorbed onto titanium dioxide, within a range from about 400 to 800 nm. In order to achieve very substantial utilization of the incident sunlight from the visible into the near infrared region, it is advantageous to use mixtures of different rylene
30 derivatives I. Occasionally, it may also be advisable also to use different rylene homologs.

The rylene derivatives I can be fixed easily and in a permanent manner to the n-semiconducting metal oxide film. The bonding is effected via the anhydride function (x1) or the carboxyl groups –COOH or –COO– formed in situ, or via the acid groups A present in the imide or condensate
35 radicals ((x2) or (x3)). The rylene derivatives I described in DE 10 2005 053 995 A1 have good suitability for use in dye-sensitized solar cells in the context of the present invention.

It is particularly preferred when the dyes, at one end of the molecule, have an anchor group which enables the fixing thereof to the n-type semiconductor film. At the other end of the
40 molecule, the dyes preferably comprise electron donors Y which facilitate the regeneration of the dye after the electron release to the n-type semiconductor, and also prevent recombination with electrons already released to the semiconductor.

For further details regarding the possible selection of a suitable dye, it is possible, for example, again to refer to DE 10 2005 053 995 A1. By way of example, it is possible especially to use ruthenium complexes, porphyrins, other organic sensitizers, and preferably rylenes.

5

The dyes can be fixed onto or into the n-semiconducting metal oxide films in a simple manner. For example, the n-semiconducting metal oxide films can be contacted in the freshly sintered (still warm) state over a sufficient period (for example about 0.5 to 24 h) with a solution or suspension of the dye in a suitable organic solvent. This can be accomplished, for example, by
10 immersing the metal oxide-coated substrate into the solution of the dye.

If combinations of different dyes are to be used, they may, for example, be applied successively from one or more solutions or suspensions which comprise one or more of the dyes. It is also possible to use two dyes which are separated by a layer of, for example, CuSCN (on this
15 subject see, for example, Tennakone, K.J., Phys. Chem. B. 2003, 107, 13758). The most convenient method can be determined comparatively easily in the individual case.

In the selection of the dye and of the size of the oxide particles of the n-semiconducting metal oxide, the organic solar cell should be configured such that a maximum amount of light is
20 absorbed. The oxide layers should be structured such that the solid p-type semiconductor can efficiently fill the pores. For instance, smaller particles have greater surface areas and are therefore capable of adsorbing a greater amount of dyes. On the other hand, larger particles generally have larger pores which enable better penetration through the p-conductor.

25 p-semiconducting organic material

As described above, the at least one DSC or sDSC of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor can comprise in particular at least one p-semiconducting organic material, preferably at least one solid p-semiconducting material, which
30 is also designated hereinafter as p-type semiconductor or p-type conductor. Hereinafter, a description is given of a series of preferred examples of such organic p-type semiconductors which can be used individually or else in any desired combination, for example in a combination of a plurality of layers with a respective p-type semiconductor, and/or in a combination of a plurality of p-type semiconductors in one layer.

35

In order to prevent recombination of the electrons in the n-semiconducting metal oxide with the solid p-conductor, it is possible to use, between the n-semiconducting metal oxide and the p-type semiconductor, at least one passivating layer which has a passivating material. This layer should be very thin and should as far as possible cover only the as yet uncovered sites of the n-semiconducting metal oxide. The passivation material may, under some circumstances, also be
40 applied to the metal oxide before the dye. Preferred passivation materials are especially one or more of the following substances: Al_2O_3 ; silanes, for example CH_3SiCl_3 ; Al^{3+} ; 4-tert-butylpyridine

(TBP); MgO; GBA (4-guanidinobutyric acid) and similar derivatives; alkyl acids; hexadecylmalonic acid (HDMA).

As described above, in the context of the organic solar cell, preferably one or more solid organic
5 p-type semiconductors are used – alone or else in combination with one or more further p-type
semiconductors which are organic or inorganic in nature. In the context of the present invention,
a p-type semiconductor is generally understood to mean a material, especially an organic
material, which is capable of conducting holes, that is to say positive charge carriers. More
particularly, it may be an organic material with an extensive π -electron system which can be
10 oxidized stably at least once, for example to form what is called a free-radical cation. For
example, the p-type semiconductor may comprise at least one organic matrix material which
has the properties mentioned. Furthermore, the p-type semiconductor can optionally comprise
one or a plurality of dopants which intensify the p-semiconducting properties. A significant
parameter influencing the selection of the p-type semiconductor is the hole mobility, since this
15 partly determines the hole diffusion length (cf. Kumara, G., Langmuir, 2002, 18, 10493-10495).
A comparison of charge carrier mobilities in different spiro compounds can be found, for
example, in T. Saragi, Adv. Funct. Mater. 2006, 16, 966-974.

Preferably, in the context of the present invention, organic semiconductors are used (i.e. low
20 molecular weight, oligomeric or polymeric semiconductors or mixtures of such semiconductors).
Particular preference is given to p-type semiconductors which can be processed from a liquid
phase. Examples here are p-type semiconductors based on polymers such as polythiophene
and polyarylamines, or on amorphous, reversibly oxidizable, nonpolymeric organic compounds,
such as the spirobifluorenes mentioned at the outset (cf., for example, US 2006/0049397 and
25 the spiro compounds disclosed therein as p-type semiconductors, which are also usable in the
context of the present invention). Preference is given to using low molecular weight organic
semiconductors, such as the low molecular weight p-type semiconducting materials as
disclosed in WO 2012/110924 A1, preferably spiro-MeOTAD, and/or one or more of the p-type
semiconducting materials disclosed in Leijtens et al., ACS Nano, VOL. 6, NO. 2, 1455-1462
30 (2012). Additionally or alternatively, one or more of the p-type semiconducting materials as
disclosed in WO 2010/094636 A1 may be used, the full content of which is herewith included by
reference. In addition, reference may also be made to the remarks regarding the p-
semiconducting materials and dopants from the above description of the prior art.

35 The p-type semiconductor is preferably producible or produced by applying at least one p-
conducting organic material to at least one carrier element, wherein the application is effected
for example by deposition from a liquid phase comprising the at least one p-conducting organic
material. The deposition can in this case once again be effected, in principle, by any desired
deposition process, for example by spin-coating, knife-coating, printing or combinations of the
40 stated and/or other deposition methods.

The organic p-type semiconductor may especially comprise at least one spiro compound and/or especially be selected from: a spiro compound, especially spiro-MeOTAD; a compound with the structural formula:

in which

10 A^1 , A^2 , A^3 are each independently optionally substituted aryl groups or heteroaryl groups,

R^1 , R^2 , R^3 are each independently selected from the group consisting of the substituents $-R$, $-OR$, $-NR_2$, $-A^4-OR$ and $-A^4-NR_2$,

where R is selected from the group consisting of alkyl, aryl and heteroaryl,

and

where A^4 is an aryl group or heteroaryl group, and

20 where n at each instance in formula I is independently a value of 0, 1, 2 or 3,

with the proviso that the sum of the individual n values is at least 2 and at least two of the R^1 , R^2 and R^3 radicals are $-OR$ and/or $-NR_2$.

25 Preferably, A^2 and A^3 are the same; accordingly, the compound of the formula (I) preferably has the following structure (Ia)

5 More particularly, as explained above, the p-type semiconductor may thus have at least one low molecular weight organic p-type semiconductor. A low molecular weight material is generally understood to mean a material which is present in monomeric, nonpolymerized or nonoligomerized form. The term "low molecular weight" as used in the present context preferably means that the p-type semiconductor has molecular weights in the range from 100 to
 10 25 000 g/mol. Preferably, the low molecular weight substances have molecular weights of 500 to 2000 g/mol.

In general, in the context of the present invention, p-semiconducting properties are understood to mean the property of materials, especially of organic molecules, to form holes and to
 15 transport these holes and/or to pass them on to adjacent molecules. More particularly, stable oxidation of these molecules should be possible. In addition, the low molecular weight organic p-type semiconductors mentioned may especially have an extensive π -electron system. More particularly, the at least one low molecular weight p-type semiconductor may be processable from a solution. The low molecular weight p-type semiconductor may especially comprise at
 20 least one triphenylamine. It is particularly preferred when the low molecular weight organic p-type semiconductor comprises at least one spiro compound. A spiro compound is understood to mean polycyclic organic compounds whose rings are joined only at one atom, which is also referred to as the spiro atom. More particularly, the spiro atom may be sp^3 -hybridized, such that the constituents of the spiro compound connected to one another via the spiro atom are, for
 25 example, arranged in different planes with respect to one another.

More preferably, the spiro compound has a structure of the following formula:

- 5 where the aryl¹, aryl², aryl³, aryl⁴, aryl⁵, aryl⁶, aryl⁷ and aryl⁸ radicals are each independently selected from substituted aryl radicals and heteroaryl radicals, especially from substituted phenyl radicals, where the aryl radicals and heteroaryl radicals, preferably the phenyl radicals, are each independently substituted, preferably in each case by one or more substituents selected from the group consisting of -O-alkyl, -OH, -F, -Cl, -Br and -I, where alkyl is preferably
- 10 methyl, ethyl, propyl or isopropyl. More preferably, the phenyl radicals are each independently substituted, in each case by one or more substituents selected from the group consisting of -O-Me, -OH, -F, -Cl, -Br and -I.

Further preferably, the spiro compound is a compound of the following formula:

15

- where R^r, R^s, R^t, R^u, R^v, R^w, R^x and R^y are each independently selected from the group consisting of -O-alkyl, -OH, -F, -Cl, -Br and -I, where alkyl is preferably methyl, ethyl, propyl or
- 20 isopropyl. More preferably, R^r, R^s, R^t, R^u, R^v, R^w, R^x and R^y are each independently selected from the group consisting of -O-Me, -OH, -F, -Cl, -Br and -I.

More particularly, the p-type semiconductor may comprise spiro-MeOTAD or consist of spiro-MeOTAD, i.e. a compound of the formula below, commercially available, for example, from Merck KGaA, Darmstadt, Germany:

5

Alternatively or additionally, it is also possible to use other p-semiconducting compounds, especially low molecular weight and/or oligomeric and/or polymeric p-semiconducting compounds.

10

In an alternative embodiment, the low molecular weight organic p-type semiconductor comprises one or more compounds of the above-mentioned general formula I, for which reference may be made, for example, to PCT application number PCT/EP2010/051826, which will be published after the priority date of the present application. The p-type semiconductor may comprise the at least one compound of the above-mentioned general formula I additionally or alternatively to the spiro compound described above.

15

The term "alkyl" or "alkyl group" or "alkyl radical" as used in the context of the present invention is understood to mean substituted or unsubstituted C₁-C₂₀-alkyl radicals in general. Preference is given to C₁- to C₁₀-alkyl radicals, particular preference to C₁- to C₈-alkyl radicals. The alkyl radicals may be either straight-chain or branched. In addition, the alkyl radicals may be substituted by one or more substituents selected from the group consisting of C₁-C₂₀-alkoxy, halogen, preferably F, and C₆-C₃₀-aryl which may in turn be substituted or unsubstituted.

20

25

Examples of suitable alkyl groups are methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl and octyl, and also isopropyl, isobutyl, isopentyl, sec-butyl, tert-butyl, neopentyl, 3,3-dimethylbutyl, 2-

ethylhexyl, and also derivatives of the alkyl groups mentioned substituted by C₆-C₃₀-aryl, C₁-C₂₀-alkoxy and/or halogen, especially F, for example CF₃.

The term "aryl" or "aryl group" or "aryl radical" as used in the context of the present invention is understood to mean optionally substituted C₆-C₃₀-aryl radicals which are derived from monocyclic, bicyclic, tricyclic or else multicyclic aromatic rings, where the aromatic rings do not comprise any ring heteroatoms. The aryl radical preferably comprises 5- and/or 6-membered aromatic rings. When the aryls are not monocyclic systems, in the case of the term "aryl" for the second ring, the saturated form (perhydro form) or the partly unsaturated form (for example the dihydro form or tetrahydro form), provided the particular forms are known and stable, is also possible. The term "aryl" in the context of the present invention thus comprises, for example, also bicyclic or tricyclic radicals in which either both or all three radicals are aromatic, and also bicyclic or tricyclic radicals in which only one ring is aromatic, and also tricyclic radicals in which two rings are aromatic. Examples of aryl are: phenyl, naphthyl, indanyl, 1,2-dihydronaphthenyl, 1,4-dihydronaphthenyl, fluorenyl, indenyl, anthracenyl, phenanthrenyl or 1,2,3,4-tetrahydronaphthyl. Particular preference is given to C₆-C₁₀-aryl radicals, for example phenyl or naphthyl, very particular preference to C₆-aryl radicals, for example phenyl. In addition, the term "aryl" also comprises ring systems comprising at least two monocyclic, bicyclic or multicyclic aromatic rings joined to one another via single or double bonds. One example is that of biphenyl groups.

The term "heteroaryl" or "heteroaryl group" or "heteroaryl radical" as used in the context of the present invention is understood to mean optionally substituted 5- or 6-membered aromatic rings and multicyclic rings, for example bicyclic and tricyclic compounds having at least one heteroatom in at least one ring. The heteroaryls in the context of the invention preferably comprise 5 to 30 ring atoms. They may be monocyclic, bicyclic or tricyclic, and some can be derived from the afore-mentioned aryl by replacing at least one carbon atom in the aryl base skeleton with a heteroatom. Preferred heteroatoms are N, O and S. The heteroaryl radicals more preferably have 5 to 13 ring atoms. The base skeleton of the heteroaryl radicals is especially preferably selected from systems such as pyridine and five-membered heteroaromatics such as thiophene, pyrrole, imidazole or furan. These base skeletons may optionally be fused to one or two six-membered aromatic radicals. In addition, the term "heteroaryl" also comprises ring systems comprising at least two monocyclic, bicyclic or multicyclic aromatic rings joined to one another via single or double bonds, where at least one ring comprises a heteroatom. When the heteroaryls are not monocyclic systems, in the case of the term "heteroaryl" for at least one ring, the saturated form (perhydro form) or the partly unsaturated form (for example the dihydro form or tetrahydro form), provided the particular forms are known and stable, is also possible. The term "heteroaryl" in the context of the present invention thus comprises, for example, also bicyclic or tricyclic radicals in which either both or all three radicals are aromatic, and also bicyclic or tricyclic radicals in which only one ring is aromatic, and also tricyclic radicals in which two rings are aromatic, where at least one of the rings, i.e. at least one aromatic or one nonaromatic ring has a heteroatom. Suitable fused heteroaromatics are, for example,

carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl. The base skeleton may be substituted at one, more than one or all substitutable positions, suitable substituents being the same as have already been specified under the definition of C₆-C₃₀-aryl. However, the hetaryl radicals are preferably unsubstituted. Suitable hetaryl radicals are, for example, pyridin-2-yl, pyridin-3-yl, pyridin-4-yl, thiophen-2-yl, thiophen-3-yl, pyrrol-2-yl, pyrrol-3-yl, furan-2-yl, furan-3-yl and imidazol-2-yl and the corresponding benzofused radicals, especially carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl.

In the context of the invention the term "optionally substituted" refers to radicals in which at least one hydrogen radical of an alkyl group, aryl group or heteroaryl group has been replaced by a substituent. With regard to the type of this substituent, preference is given to alkyl radicals, for example methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl and octyl, and also isopropyl, isobutyl, isopentyl, sec-butyl, tert-butyl, neopentyl, 3,3-dimethylbutyl and 2-ethylhexyl, aryl radicals, for example C₆-C₁₀-aryl radicals, especially phenyl or naphthyl, most preferably C₆-aryl radicals, for example phenyl, and hetaryl radicals, for example pyridin-2-yl, pyridin-3-yl, pyridin-4-yl, thiophen-2-yl, thiophen-3-yl, pyrrol-2-yl, pyrrol-3-yl, furan-2-yl, furan-3-yl and imidazol-2-yl, and also the corresponding benzofused radicals, especially carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl. Further examples include the following substituents: alkenyl, alkynyl, halogen, hydroxyl.

The degree of substitution here may vary from monosubstitution up to the maximum number of possible substituents.

Preferred compounds of the formula I for use in accordance with the invention are notable in that at least two of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. The at least two radicals here may be only -OR radicals, only -NR₂ radicals, or at least one -OR and at least one -NR₂ radical.

Particularly preferred compounds of the formula I for use in accordance with the invention are notable in that at least four of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. The at least four radicals here may be only -OR radicals, only -NR₂ radicals or a mixture of -OR and -NR₂ radicals.

Very particularly preferred compounds of the formula I for use in accordance with the invention are notable in that all of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. They may be only -OR radicals, only -NR₂ radicals or a mixture of -OR and -NR₂ radicals.

In all cases, the two R in the -NR₂ radicals may be different from one another, but they are preferably the same.

Preferably, A¹, A² and A³ are each independently selected from the group consisting of

76

in which

5

m is an integer from 1 to 18,

R⁴ is alkyl, aryl or heteroaryl, where R⁴ is preferably an aryl radical, more preferably a phenyl radical,

10

R⁵, R⁶ are each independently H, alkyl, aryl or heteroaryl,

where the aromatic and heteroaromatic rings of the structures shown may optionally have further substitution. The degree of substitution of the aromatic and heteroaromatic rings here may vary from monosubstitution up to the maximum number of possible substituents.

15

Preferred substituents in the case of further substitution of the aromatic and heteroaromatic rings include the substituents already mentioned above for the one, two or three optionally substituted aromatic or heteroaromatic groups.

20

Preferably, the aromatic and heteroaromatic rings of the structures shown do not have further substitution.

More preferably, A¹, A² and A³ are each independently

25

more preferably

More preferably, the at least one compound of the formula (I) has one of the following structures:

5

ID367

10

ID522

In an alternative embodiment, the organic p-type semiconductor comprises a compound of the type ID322 having the following structure:

The compounds for use in accordance with the invention can be prepared by customary methods of organic synthesis known to those skilled in the art. References to relevant (patent) literature can additionally be found in the synthesis examples adduced below.

Second electrode

a) General remarks

10

The second electrode may be a bottom electrode facing the substrate or else a top electrode facing away from the substrate. As outlined above, the second electrode may be fully or partially transparent or, else, may be intransparent. As used herein, the term partially transparent refers to the fact that the second electrode may comprise transparent regions and intransparent regions.

15

In case the second electrode is fully or partially transparent, the second electrode may comprise at least one transparent conductive electrode material, which may be selected from the group consisting of: an inorganic transparent conductive material; an organic transparent conductive material. As an example of an inorganic conductive transparent material, a metal oxide may be used, such as ITO and/or FTO. As an example of an organic transparent conductive material, one or more electrically conductive polymer materials may be used. As used herein, the term "transparent" refers to the actual layer or layer setup of the second electrode. Thus, the transparency may be generated by using thin layers, such as layers having a thickness of less than 100 nm, more preferably less than 50 nm.

20

One or more materials of the following group of materials may be used: at least one metallic material, preferably a metallic material selected from the group consisting of aluminum, silver, platinum, gold; at least one nonmetallic inorganic material, preferably LiF; at least one organic conductive material, preferably at least one electrically conductive polymer and, more preferably, at least one transparent electrically conductive polymer.

25

30

The second electrode may comprise one or more metals in a pure form and/or may comprise one or more metal alloys. The second electrode may further comprise a single layer and/or may comprise a layer setup of two or more layers, wherein, preferably at least one layer is a metal layer comprising one or more metals or metal alloys. As an example, the second electrode may comprise at least one metal selected from the group listed in the preceding paragraph in a pure form and/or as a component of an alloy. As an example, the second electrode may comprise at least one alloy selected from the group consisting of: a molybdenum alloy; a niobium alloy; a neodymium alloy; an aluminum alloy. Most preferably, the second electrode may comprise at least one alloy selected from the group consisting of: MoNb; AlNd; MoNb. As an example, a layer setup comprising two or more layers of two or more of the named alloys may be used, such as a layer setup comprising the following layers: MoNb / AlNd / MoNb. As an example, the following layer thicknesses may be used: MoNb 30nm / AlNd 100 nm / MoNb 30nm. Additionally or alternatively, however, other setups and/or other layer thicknesses may be used.

The second electrode may comprise at least one metal electrode, wherein one or more metals in pure form or as a mixture/alloy, such as especially aluminum or silver may be used.

Additionally or alternatively, nonmetallic materials may be used, such as inorganic materials and/or organic materials, both alone and in combination with metal electrodes. As an example, the use of inorganic/organic mixed electrodes or multilayer electrodes is possible, for example the use of LiF/Al electrodes. Additionally or alternatively, conductive polymers may be used. Thus, the second electrode of the at least one transversal optical sensor and/or the second electrode of the at least one longitudinal optical sensor preferably may comprise one or more conductive polymers.

As an example, one or more electrically conductive polymers may be used, selected from the group consisting of: polyaniline (PANI) and/or its chemical relatives; a polythiophene and/or its chemical relatives, such as poly(3-hexylthiophene) (P3HT) and/or PEDOT:PSS (poly(3,4-ethylenedioxythiophene) poly(styrenesulfonate)). Additionally or alternatively, one or more of the conductive polymers as disclosed in EP2507286 A2, EP2205657 A1 or EP2220141 A1

In addition or alternatively, inorganic conductive materials may be used, such as inorganic conductive carbon materials, such as carbon materials selected from the group consisting of: graphite, graphene, carbon nano-tubes, carbon nano-wires.

In addition, it is also possible to use electrode designs in which the quantum efficiency of the components is increased by virtue of the photons being forced, by means of appropriate reflections, to pass through the absorbing layers at least twice. Such layer structures are also referred to as "concentrators" and are likewise described, for example, in WO 02/101838 (especially pages 23-24).

The second electrode may be identical for the at least one transversal optical sensor and the at least one longitudinal optical sensor. Still, different setups of the second electrode for the transversal optical sensor and the longitudinal optical sensor may be used.

5 b) Second electrode of the transversal sensor device

Preferably, the second electrode for the at least one transversal sensor device is at least partially transparent. As an example, the second electrode of the transversal sensor device may comprise at least one transparent electrode layer which covers a sensor region, preferably a
10 sensor area, of the transversal optical sensor. As outlined above, the at least one transparent electrode layer preferably may comprise at least one layer of an electrically conductive polymer, preferably a transparent electrically conductive polymer.

Additionally, the second electrode of the transversal sensor device may comprise two or more
15 partial electrodes, which, preferably, may be made of one or more metals, such as one or more of the metals and/or metal alloys listed above. As an example, the two or more partial electrodes may form a frame which surrounds the sensor region, preferably the sensor area, of the transversal optical sensor. The frame may have a polygonal shape, such as a rectangular or, preferably, a square shape. Preferably, on each side of the polygon, preferably the rectangle
20 or square, one partial electrodes is provided, such as a partial electrode being formed as a bar fully or partially extending along the side.

The at least one electrically conductive polymer may have an electrical conductivity of at least one order of magnitude below electrical conductivity of the material of the partial electrodes,
25 preferably of at least two orders of magnitude below. The at least one electrically conductive polymer may electrically interconnect the partial electrodes. Thus, as outlined above, the partial electrodes may form a frame surrounding a sensor region, preferably a sensor area, of the transversal optical sensor. The at least one layer of the electrically conductive polymer may form a transparent, electrically conductive layer which fully or partially covers the sensor region
30 and which electrically contacts the partial electrodes. As an example, the partial electrodes may comprise metal strips or metal bars along the sides of a rectangle, wherein an inner region of the rectangle forms the sensor region, wherein the at least one layer of the electrically conductive polymer forms one or more transparent electrode layers fully or partially covering the inner region of the rectangle and electrically contacting the metal strips or bars.

35 In case two or more partial electrodes are used which, preferably, are electrically interconnected by at least one layer of an electrically conductive polymer, each of the partial electrodes may be contacted individually, such as by one or more electrical leads or contact pads. Thus, by electrically contacting the partial electrodes, an electrical current through each of the partial
40 electrodes may be measured individually, such as by using an individual current measurement device and/or by using a sequential measurement scheme for individually detecting the currents through the partial electrodes. The detector, for the purpose of measuring the currents through

the partial electrodes, may provide an appropriate measurement setup comprising one or more current measurement devices.

c) Second electrode of the longitudinal sensor device

5

Generally, with regard to the at least one second electrode of the at least one longitudinal sensor device, the above-mentioned details regarding the transversal sensor device may apply mutatis mutandis. Again, the second electrode of the at least one longitudinal sensor device preferably is transparent. In case a plurality of longitudinal sensor devices is provided, such as
10 in a stack, preferably all second electrodes of the longitudinal sensor devices are transparent but the second electrode of the last longitudinal sensor device facing away from the object. The second electrode of the last longitudinal sensor device may be transparent or intransparent.

With regard to materials which may be used for the second electrode of the longitudinal sensor
15 device, reference may be made to the above-mentioned materials, which may be selected from metallic materials, nonmetallic inorganic materials and electrically conductive organic materials.

Again, the second electrode of the longitudinal optical sensor or, in case a plurality of longitudinal optical sensors is provided, of at least one of the longitudinal optical sensors may
20 optionally be subdivided into partial electrodes which may be contacted individually. However, since for the purpose of the at least one longitudinal optical sensor generally only one individual longitudinal sensor signal is required per longitudinal optical sensor, the second electrode of the at least one longitudinal optical sensor may as well be designed to provide a single sensor signal and, thus, may provide a single electrode contact only.

25

The second electrode of the longitudinal optical sensor, again, preferably may comprise one or more layers of an electrically conductive polymer, such as one or more of the polymers mentioned above. The at least one layer of the electrically conductive polymer, which preferably is transparent, may fully or partially cover the sensor region, preferably a sensor area, of the
30 longitudinal optical sensor. In addition, one or more contact pads may be provided which electrically contact the at least one electrically conductive polymer layer. This at least one contact pad for the second electrode of the longitudinal optical sensor preferably may be made of at least one metal, such as at least one of the methods mentioned above, and/or may fully or partially be made of at least one inorganic conductive material, such as one or more transparent
35 conductive oxides, such as one or more of the conductive oxides mentioned above with regard to the first electrode.

Encapsulation

40 The at least one transversal optical sensor and/or the at least one longitudinal optical sensor may further be encapsulated and/or packaged, in order to provide protection against

environmental influences, such as oxygen and/or humidity. Thereby, an increased long-term stability may be provided.

5 Therein, each of the optical sensors may be encapsulated individually. Thus, an individual encapsulation may be provided for each of the optical sensors, such as an encapsulation for the transversal optical sensor or each of the transversal optical sensors, and an individual encapsulation for the longitudinal optical sensor or for each of the longitudinal optical sensors. Additionally or alternatively, a plurality of optical sensors may be encapsulated as a group. Thus, an encapsulation may be provided which encapsulates more than one optical sensor,
10 such as a plurality of transversal optical sensors, a plurality of longitudinal optical sensors, or at least one transversal optical sensor and at least one longitudinal optical sensor.

For the purpose of encapsulation, various techniques may be used. Thus, the detector may comprise an airtight housing which protects the optical sensors. Additionally or alternatively,
15 specifically in case organic photodetectors and, more preferably, DSCs or sDSCs are used, an encapsulation by one or more lids interacting with a substrate of the optical sensors may be used. Thus, a lid made of a metal, a ceramic material or a glass material may be glued to a substrate of the optical sensors, wherein a layer setup is located in inner space of the lid. Two or more contact leads for contacting the at least one first electrode and the at least one second
20 electrode may be provided which may be contacted from the outside of the lid.

Various other encapsulation techniques may be used alternatively or in addition. Thus, encapsulation by one or more encapsulation layers may be provided. The at least one encapsulation layer may be deposited on top of a layer setup of the devices. Thus, one or more
25 organic and/or inorganic encapsulation materials such as one or more barrier materials may be used.

Synthesis examples:

30 Syntheses of various compounds which can be used in dye solar cells in the context of the present invention, in particular as p-type semiconductors, are listed by way of example in WO 2012/110924 A1, the content of which is herewith included by reference.

35 Overall, in the context of the present invention, the following embodiments are regarded as particularly preferred:

Embodiment 1: A detector for determining a position of at least one object, comprising:

- 40 - at least one transversal optical sensor, the transversal optical sensor being adapted to determine a transversal position of at least one light beam traveling from the object to the detector, the transversal position being a position in at least one dimension

perpendicular to an optical axis of the detector, the transversal optical sensor being adapted to generate at least one transversal sensor signal;

- at least one longitudinal optical sensor, wherein the longitudinal optical sensor has at least one sensor region, wherein the longitudinal optical sensor is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region by the light beam, wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam in the sensor region;
- at least one evaluation device, wherein the evaluation device is designed to generate at least one item of information on a transversal position of the object by evaluating the transversal sensor signal and to generate at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal.

Embodiment 2: The detector according to the preceding embodiment, wherein the transversal optical sensor is a photo detector having at least one first electrode, at least one second electrode and at least one photovoltaic material, wherein the photovoltaic material is embedded in between the first electrode and the second electrode, wherein the photovoltaic material is adapted to generate electric charges in response to an illumination of the photovoltaic material with light, wherein the second electrode is a split electrode having at least two partial electrodes, wherein the transversal optical sensor has a sensor region, wherein the at least one transversal sensor signal indicates a position of the light beam in the sensor region, preferably a sensor area.

Embodiment 3: The detector according to the preceding embodiment, wherein electrical currents through the partial electrodes are dependent on a position of the light beam in the sensor region.

Embodiment 4: The detector according to the preceding embodiment, wherein the transversal optical sensor is adapted to generate the transversal sensor signal in accordance with the electrical currents through the partial electrodes.

Embodiment 5: The detector according to any of the two preceding embodiments, wherein the detector, preferably the transversal optical sensor and/or the evaluation device, is adapted to derive the information on the transversal position of the object from at least one ratio of the currents through the partial electrodes.

Embodiment 6: The detector according to any of the four preceding embodiments, wherein at least four partial electrodes are provided.

Embodiment 7: The detector according to any of the five preceding embodiments, wherein the photovoltaic material comprises at least one organic photovoltaic material and wherein the transversal optical sensor is an organic photo detector.

Embodiment 8: The detector according to any of the six preceding embodiments, wherein the organic photo detector is a dye-sensitized solar cell.

5 Embodiment 9: The detector according to the preceding embodiment, wherein the dye-sensitized solar cell is a solid dye-sensitized solar cell, comprising a layer setup embedded in between the first electrode and the second electrode, the layer setup comprising at least one n-semiconducting metal oxide, at least one dye, and at least one solid p-semiconducting organic material.

10

Embodiment 10: The detector according to any of the eight preceding embodiments, wherein the first electrode at least partially is made of at least one transparent conductive oxide, wherein the second electrode at least partially is made of an electrically conductive polymer, preferably a transparent electrically conductive polymer.

15

Embodiment 11: The detector according to the preceding embodiment, wherein the conductive polymer is selected from the group consisting of: a poly-3,4-ethylenedioxythiophene (PEDOT), preferably PEDOT being electrically doped with at least one counter ion, more preferably PEDOT doped with sodium polystyrene sulfonate (PEDOT:PSS); a polyaniline (PANI); a

20

polythiophene.

Embodiment 12: The detector according to any of the two preceding embodiments, wherein the conductive polymer provides an electric resistivity of 0.1 – 20 k Ω between the partial electrodes, preferably an electric resistivity of 0.5 – 5.0 k Ω and, more preferably, an electric resistivity of 1.0

25

– 3.0 k Ω .

Embodiment 13: The detector according to any of the preceding embodiments, wherein at least one of the transversal optical sensor and the longitudinal optical sensor is a transparent optical sensor.

30

Embodiment 14: The detector according to the preceding embodiment, wherein the light beam passes through the transparent optical sensor before impinging on the other one of the transversal optical sensor and the longitudinal optical sensor.

35 Embodiment 15: The detector according to any one of the preceding embodiments, wherein the detector further comprises at least one imaging device.

Embodiment 16: The detector according to the preceding claim, wherein the detector comprises a stack of optical sensors, the optical sensors comprising the at least one transversal optical

40

sensor and the at least one longitudinal optical sensor, the stack further comprising the imaging device.

Embodiment 17: The detector according to the preceding claim, wherein the imaging device is located in a position of the stack furthest away from the object.

5 Embodiment 18: The detector according to any of the three preceding embodiments, wherein the light beam passes through the at least one longitudinal optical sensor before illuminating the imaging device.

Embodiment 19: The detector according to any of the four preceding embodiments, wherein the imaging device comprises a camera.

10

Embodiment 20: The detector according to any of the five preceding embodiments, wherein the imaging device comprises at least one of: an inorganic camera; a monochrome camera; a multichrome camera; a full-color camera; a pixelated inorganic chip; a pixelated organic camera; a CCD chip, preferably a multi-color CCD chip or a full-color CCD chip; a CMOS chip; an IR camera; an RGB camera.

15

Embodiment 21: The detector according to any of the preceding embodiments, wherein the transversal optical sensor and the longitudinal optical sensor at least partially are identical.

20 Embodiment 22: The detector according to any of the preceding embodiments, wherein the transversal optical sensor and the longitudinal optical sensor at least partially are independent optical sensors.

Embodiment 23: The detector according to any of the preceding embodiments, wherein the transversal optical sensor and the longitudinal optical sensor are stacked along the optical axis such that a light beam travelling along the optical axis both impinges on the transversal optical sensor and on the longitudinal optical sensor.

25

Embodiment 24: The detector according to the preceding embodiment, wherein the light beam subsequently passes through the transversal optical sensor and the longitudinal optical sensor or vice versa.

30

Embodiment 25: The detector according to any of the preceding embodiments, wherein the detector furthermore has at least one modulation device for modulating the illumination.

35

Embodiment 26: The detector according to the preceding embodiment, wherein the detector is designed to detect at least two longitudinal sensor signals in the case of different modulations, in particular at least two sensor signals at respectively different modulation frequencies, wherein the evaluation device is designed to generate the at least one item of information on the longitudinal position of the object by evaluating the at least two longitudinal sensor signals.

40

Embodiment 27: The detector according to any of the preceding embodiments, wherein the longitudinal optical sensor is furthermore designed in such a way that the longitudinal sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination.

5

Embodiment 28: The detector according to any of the preceding embodiments, wherein the sensor region of the longitudinal optical sensor is exactly one continuous sensor region, wherein the longitudinal sensor signal is a uniform sensor signal for the entire sensor region.

10 Embodiment 29: The detector according to any of the preceding embodiments, wherein the sensor region of the transversal optical sensor and/or the sensor region of the longitudinal optical sensor is or comprises a sensor area, the sensor area being formed by a surface of the respective device, wherein the surface faces towards the object or faces away from the object.

15 Embodiment 30: The detector according to any of the preceding embodiments, wherein the longitudinal sensor signal is selected from the group consisting of a current and a voltage.

Embodiment 31: The detector according to any of the preceding embodiments, wherein the transversal sensor signal is selected from the group consisting of a current and a voltage or any
20 signal derived thereof.

Embodiment 32: The detector according to any of the preceding embodiments, wherein the longitudinal optical sensor comprises at least one semiconductor detector, in particular an organic semiconductor detector comprising at least one organic material, preferably an organic
25 solar cell and particularly preferably a dye solar cell or dye-sensitized solar cell, in particular a solid dye solar cell or a solid dye-sensitized solar cell.

Embodiment 33: The detector according to the preceding embodiment, wherein the longitudinal optical sensor comprises at least one first electrode, at least one n-semiconducting metal oxide,
30 at least one dye, at least one p-semiconducting organic material, preferably a solid p-semiconducting organic material, and at least one second electrode.

Embodiment 34: The detector according to the preceding embodiment, wherein both the first electrode and the second electrode are transparent.

35

Embodiment 35: The detector according to any of the preceding embodiments, wherein the evaluation device is designed to generate the at least one item of information on the longitudinal position of the object from at least one predefined relationship between the geometry of the illumination and a relative positioning of the object with respect to the detector, preferably taking
40 account of a known power of the illumination and optionally taking account of a modulation frequency with which the illumination is modulated.

Embodiment 36: The detector according to any of the preceding embodiments, furthermore comprising at least one transfer device, wherein the transfer device is designed to feed light emerging from the object to the transversal optical sensor and the longitudinal optical sensor.

- 5 Embodiment 37: The detector according to any of the preceding embodiments, furthermore comprising at least one illumination source.

Embodiment 38: The detector according to the preceding embodiment, wherein the illumination source is selected from: an illumination source, which is at least partly connected to the object
10 and/or is at least partly identical to the object; an illumination source which is designed to at least partly illuminate the object with a primary radiation, wherein the light beam preferably is generated by a reflection of the primary radiation on the object and/or by light emission by the object itself, stimulated by the primary radiation.

- 15 Embodiment 39: The detector according to any of the preceding embodiments, wherein the detector has a plurality of longitudinal optical sensors, wherein the longitudinal optical sensors are stacked.

Embodiment 40: The detector according to the preceding embodiment, wherein the longitudinal
20 optical sensors are stacked along the optical axis.

Embodiment 41: The detector according to any of the two preceding embodiments, wherein the longitudinal optical sensors form a longitudinal optical sensor stack, wherein the sensor regions of the longitudinal optical sensors are oriented perpendicular to the optical axis.

- 25 Embodiment 42: The detector according to any of the three preceding embodiments, wherein the transversal optical sensor is located on a side of the stacked longitudinal optical sensors facing the object.

30 Embodiment 43: The detector according to any of the four preceding embodiments, wherein the longitudinal optical sensors are arranged such that a light beam from the object illuminates all longitudinal optical sensors, preferably sequentially, wherein at least one longitudinal sensor signal is generated by each longitudinal optical sensor.

35 Embodiment 44: The detector according to any of the five preceding embodiments, wherein a last longitudinal optical sensor is arranged in a manner that the light beam first illuminates all other longitudinal optical sensors apart from the last longitudinal optical sensor, until the light beam finally illuminates the last longitudinal optical sensor.

- 40 Embodiment 45: The detector according to the preceding embodiment, wherein the last longitudinal optical sensor is intransparent with respect to the light beam.

Embodiment 46: The detector according to any of the seven preceding embodiments, wherein at least two of the longitudinal optical sensors have a differing spectral sensitivities.

5 Embodiment 47: The detector according to the preceding embodiment, wherein the differing spectral sensitivities are arranged over a spectral range allowing each of the at least two of the longitudinal optical sensors to be sensitive to a specific color.

10 Embodiment 48: The detector according to the preceding embodiment, wherein the longitudinal optical sensors comprise at least one first longitudinal optical sensor absorbing light in a first spectral range, wherein the longitudinal optical sensors further comprise at least one second longitudinal optical sensor absorbing light in a second spectral range being different from the first spectral range, wherein the longitudinal optical sensors further comprise at least one third longitudinal optical sensor absorbing light in a third spectral range which includes both the first spectral range and the second spectral range.

15 Embodiment 49: The detector according to any of the six preceding embodiments, wherein the evaluation device is adapted to normalize the longitudinal sensor signals and to generate the information on the longitudinal position of the object independent from an intensity of the light beam.

20 Embodiment 50: The detector according to any of the seven preceding embodiments, wherein the evaluation device is adapted to recognize whether the light beam widens or narrows, by comparing the longitudinal sensor signals of different longitudinal sensors.

25 Embodiment 51: The detector according to any of the preceding embodiments, wherein the stack of at least two optical sensors is partially or fully be immersed in an oil, in a liquid and/or in a solid material.

30 Embodiment 52: The detector according to the preceding embodiment, wherein the oil, the liquid, and/or the solid material are transparent at least over a part of the ultraviolet, visible, and/or infrared spectral range.

35 Embodiment 53: The detector according to any of the two preceding embodiments, wherein the solid material is generable by using at least one curable substance and treating the curable substance with a treatment, by which treatment the curable substance is cured into the solid material.

40 Embodiment 54: The detector according to any of the three preceding embodiments, wherein a region between the at least two optical sensors is partially or fully filled with a substance.

Embodiment 55: The detector according to the preceding embodiment, wherein the substance exhibits a refractive index differing from that of the optical sensors adjoining to the substance on one or both sides of the region.

- 5 Embodiment 56: The detector according to any of the preceding embodiments, wherein the at least one transversal optical sensor and/or the at least one longitudinal optical sensor uses at least two transparent substrates.

- 10 Embodiment 57: The detector according to the preceding embodiment, wherein the substrates exhibit identical properties.

- 15 Embodiment 58: The detector according to any of the two preceding embodiments, wherein the substrates differ from each other with regard to a geometrical quantity and/or to a material quantity related to the substrates.

Embodiment 59: The detector according to the preceding embodiment, wherein the substrates differ from each other by the thickness.

- 20 Embodiment 60: The detector according to any of the two preceding embodiments, wherein the substrates differ from each other by shape.

- 25 Embodiment 61: The detector according to the preceding embodiment, wherein the shape is selected from the group comprising a planar, a planar-convex, a planar-concave, a biconvex, a biconcave or any other form employed for optical purposes.

Embodiment 62: The detector according to any of the six preceding embodiments, wherein the substrates are rigid or flexible.

- 30 Embodiment 63: The detector according to any of the seven preceding embodiments, wherein the substrates are covered or coated.

Embodiment 63: The detector according to any of the eight preceding embodiments, wherein the substrate is shaped in a manner that it exhibits a mirror effect.

- 35 Embodiment 64: The detector according to the preceding embodiment, wherein the substrate is shaped in a manner that it exhibits the effect of a dichroic mirror.

- 40 Embodiment 65: The detector according to any of the preceding embodiments, wherein the evaluation device is adapted to generate the at least one item of information on the longitudinal position of the object by determining a diameter of the light beam from the at least one longitudinal sensor signal.

Embodiment 66: The detector according to the preceding embodiment, wherein the evaluation device is adapted to compare the diameter of the light beam with known beam properties of the light beam in order to determine the at least one item of information on the longitudinal position of the object, preferably from a known dependency of a beam diameter of the light beam on at least one propagation coordinate in a direction of propagation of the light beam and/or from a known Gaussian profile of the light beam.

Embodiment 67: The detector according to any of the preceding embodiments, wherein the detector comprises an optically sensitive element.

Embodiment 68: The detector according to the preceding embodiment, wherein the optically sensitive element is located between the transfer device and the optical sensor.

Embodiment 69: The detector according to any of the two preceding embodiments, wherein the optically sensitive element comprises a wavelength-sensitive element, a phase-sensitive element, and/or a polarization-sensitive element.

Embodiment 70: The detector according to the preceding embodiment, wherein the wavelength-sensitive element comprises one or more of a prism, a grating, a dichroitic mirror, a color wheel, or a color drum.

Embodiment 71: The detector according to the preceding embodiment, wherein the color wheel comprises a sequential color recapture wheel.

Embodiment 72: The detector according to any of the two preceding embodiments, wherein the color wheel or the color drum comprises two or more of at least one red, green, blue, white, cyan, yellow, or magenta segment.

Embodiment 73: The detector according to embodiment 54, wherein the polarization-sensitive element comprises a filter wheel using an elliptically polarizing filter.

Embodiment 74: The detector according to the preceding embodiment, wherein the polarization-sensitive element comprises a filter wheel using a circular polarizing filter.

Embodiment 75: The detector according to any of the two preceding embodiments, wherein the optically sensitive element comprises at least two wheels, at least one first wheel and at least one second wheel, wherein the first wheel constitutes a color wheel and wherein the second wheel constitutes an elliptically polarizing filter.

Embodiment 76: An arrangement comprising at least two detectors according to any of the preceding embodiments.

Embodiment 77: An arrangement according to the preceding embodiment, wherein the at least two detectors have identical optical properties.

Embodiment 78: The arrangement according to any of the two preceding embodiments, wherein
5 the arrangement further comprises at least one illumination source.

Embodiment 79: A human-machine interface for exchanging at least one item of information between a user and a machine, in particular for inputting control commands, wherein the human-machine interface comprises at least one detector according to any of the preceding
10 embodiments relating to a detector, wherein the human-machine interface is designed to generate at least one item of geometrical information of the user by means of the detector wherein the human-machine interface is designed to assign to the geometrical information at least one item of information, in particular at least one control command.

15 Embodiment 80: The human-machine interface according to the preceding embodiment, wherein the at least one item of geometrical information of the user is selected from the group consisting of: a position of a body of the user; a position of at least one body part of the user; an orientation of a body of the user; an orientation of at least one body part of the user.

20 Embodiment 81: The human-machine interface according to any of the two preceding embodiments, wherein the human-machine interface further comprises at least one beacon device connectable to the user, wherein the human-machine interface is adapted such that the detector may generate an information on the position of the at least one beacon device.

25 Embodiment 82: The human-machine interface according to the preceding embodiment, wherein the beacon device is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user.

Embodiment 83: The human-machine interface according to the preceding embodiment,
30 wherein the beacon device comprises at least one illumination source adapted to generate at least one light beam to be transmitted to the detector.

Embodiment 84: The human-machine interface according to any of the two preceding
embodiments, wherein the beacon device comprises at least one reflector adapted to reflect
35 light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

Embodiment 85: The human-machine interface according to any of the three preceding
embodiments, wherein the beacon device comprises at least one of: a garment to be worn by
40 the user, preferably a garment selected from the group consisting of a glove, a jacket, a hat, shoes, trousers and a suit; a stick that may be held by hand; a bat; a club; a racket; a cane; a toy, such as a toy gun.

Embodiment 86: An entertainment device for carrying out at least one entertainment function, in particular a game, wherein the entertainment device comprises at least one human-machine interface according to any of the preceding embodiments referring to a human-machine
5 interface, wherein the entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface, wherein the entertainment device is designed to vary the entertainment function in accordance with the information.

10 Embodiment 87: A tracking system for tracking the position of at least one movable object, the tracking system comprising at least one detector according to any of the preceding embodiments referring to a detector, the tracking system further comprising at least one track controller, wherein the track controller is adapted to track a series of positions of the object,
15 each position comprising at least one item of information on a transversal position of the object at a specific point in time and at least one item of information on a longitudinal position of the object at a specific point in time.

Embodiment 88: The tracking system according to the preceding embodiment, wherein the tracking system further comprises at least one beacon device connectable to the object,
20 wherein the tracking system is adapted such that the detector may generate an information on the position of the object of the at least one beacon device.

Embodiment 89: The tracking system according to the preceding embodiment, wherein the beacon device comprises at least one illumination source adapted to generate at least one light
25 beam to be transmitted to the detector.

Embodiment 90: The tracking system according to any of the two preceding embodiments, wherein the beacon device comprises at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the
30 detector.

Embodiment 91: The tracking system according to any of the preceding embodiments referring to a tracking system, wherein the track controller is adapted to initiate at least one action in accordance with an actual position of the object.
35

Embodiment 92: The tracking system according to the preceding embodiment, wherein the action is selected from the group consisting of: a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.
40

Embodiment 93: A camera for imaging at least one object, the camera comprising at least one detector according to any one of the preceding embodiments referring to a detector.

Embodiment 94: A method for determining a position of at least one object, in particular using a detector according to any of the preceding embodiments relating to a detector,

- 5 - wherein at least one transversal optical sensor of a detector is used, wherein the transversal optical sensor determines a transversal position of at least one light beam traveling from the object to the detector, the transversal position being a position in at least one dimension perpendicular to an optical axis of the detector, wherein the transversal optical sensor generates at least one transversal sensor signal;
- 10 - wherein at least one longitudinal optical sensor of the detector is used, wherein the longitudinal optical sensor has at least one sensor region, wherein the longitudinal optical sensor generates at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region by the light beam, wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam in the sensor region;
- 15 - wherein at least one evaluation device is used, wherein the evaluation device generates at least one item of information on a transversal position of the object by evaluating the transversal sensor signal and wherein the evaluation device further generates at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal.

20

Embodiment 95: The use of a detector according to any of the preceding embodiments relating to a detector, for a purpose of use, selected from the group consisting of: a distance measurement, in particular in traffic technology; a position measurement, in particular in traffic technology; an entertainment application; a security application; a human-machine interface application; a tracking application; a photography application; an imaging application or camera application; a mapping application for generating maps of at least one space.

Exemplary embodiments

25 Detector

Figure 1A illustrates, in a highly schematic illustration, an exemplary embodiment of a detector 110 according to the invention, for determining a position of at least one object 112. The detector 110 preferably may form a camera 111 or may be part of a camera 111. Other
30 embodiments are feasible.

The detector 110 comprises a plurality of optical sensors 114, which, in the specific embodiment, are all stacked along an optical axis 116 of the detector 110. Specifically, the optical axis 116 may be an axis of symmetry and/or rotation of the setup of the optical sensors
35 114. The optical sensors 114 may be located inside a housing 118 of the detector 110. Further, at least one transfer device 120 may be comprised, such as one or more optical systems, preferably comprising one or more lenses 122. An opening 124 in the housing 118, which, preferably, is located concentrically with regard to the optical axis 116, preferably defines a direction of view 126 of the detector 110. A coordinate system 128 may be defined, in which a
40 direction parallel or antiparallel to the optical axis 116 is defined as a longitudinal direction, whereas directions perpendicular to the optical axis 116 may be defined as transversal directions. In the coordinate system 128, symbolically depicted in Fig. 1A, a longitudinal

direction is denoted by z and transversal directions are denoted by x and y, respectively. Other types of coordinate systems 128 are feasible.

5 The optical sensors 114 comprise at least one transversal optical sensor 130 and, in this embodiment, a plurality of longitudinal optical sensors 132. The longitudinal optical sensors 132 form a longitudinal optical sensor stack 134. In the embodiment shown in Fig. 1A, five longitudinal sensors 132 are depicted. It shall be noted, however, that embodiments having a different number of longitudinal optical sensors 132 are feasible.

10 The transversal optical sensor 132 comprises a sensor region 136, which, preferably, is transparent to a light beam 138 travelling from the object 112 to the detector 110. The transversal optical sensor 130 is adapted to determine a transversal position of the light beam 138 in one or more transversal directions, such as in direction x and/or in direction y. Therein, embodiments are feasible in which a transversal position in only one transversal direction is
15 determined, embodiments in which transversal positions in more than one transversal direction are determined by one and the same transversal optical sensor 130, and embodiments in which a transversal position in a first transversal direction is determined by a first transversal optical sensor and wherein at least one further transversal position in at least one further transversal direction is determined by at least one further transversal optical sensor.

20 The at least one transversal optical sensor 130 is adapted to generate at least one transversal sensor signal. This transversal sensor signal may be transmitted by one or more transversal signal leads 140 to at least one evaluation device 142 of the detector 110, which will be explained in further detail below.

25 The longitudinal optical sensors 132 each comprise at least one sensor region 136, too. Preferably, one, more or all of the longitudinal optical sensors 132 are transparent, but the last longitudinal optical sensor 144 of the longitudinal optical sensor stack 134, i.e. the longitudinal optical sensor 132 on the side of the stack 134 facing away from the object 112. This last
30 longitudinal sensor 144 may fully or partially be intransparent.

Each of the longitudinal optical sensors 132 is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the respective sensor region 136 by the light beam 138. The longitudinal sensor signals, given the same total power of the
35 illumination, is dependent on a beam cross-section of the light beam 138 in the respective sensor region 136, as will be outlined in further detail below. Via one or more longitudinal signal leads 146, the longitudinal sensor signals may be transmitted to the evaluation device 142. As will be outlined in further detail below, the evaluation device may be designed to generate at least one item of information on at least one transversal position of the object 112 by evaluating
40 the at least one transversal sensor signal and to generate at least one item of information on at least one longitudinal position of the object 112 by evaluating the longitudinal sensor signal. For this purpose, the evaluation device 142 may comprise one or more electronic devices and/or

one or more software components, in order to evaluate the sensor signals, which is symbolically denoted by transversal evaluation unit 148 (denoted by "xy") and longitudinal evaluation unit 150 (denoted by "z"). By combining results derived by these evolution units 148, 150, a position information 152, preferably a three-dimensional position information, may be generated (denoted by "x, y, z").

The evaluation device 142 may be part of a data processing device 154 and/or may comprise one or more data processing devices 154. The evaluation device 142 may be fully or partially integrated into the housing 118 and/or may fully or partially be embodied as a separate device which is electrically connected in a wireless or wire-bound fashion to the optical sensors 114. The evaluation device 142 may further comprise one or more additional components, such as one or more electronic hardware components and/or one or more software components, such as one or more measurement units (not depicted in Fig. 1A) and/or one or more transformation units 156. Symbolically, in Fig. 1A, one optional transformation unit 156 is depicted which may be adapted to transform at least two transversal sensor signals into a common signal or common information.

In the following, embodiments of the transversal optical sensor 130 and the at least one longitudinal optical sensor 132 are disclosed. It shall be noted, however, that other embodiments are feasible. Thus, in the embodiments disclosed hereinafter, the optical sensors 114 are all designed as solid dye-sensitized solar cells (sDSCs). It shall be noted, however, that other embodiments are feasible.

Fig. 1B illustrates, in a highly schematic illustration, a further exemplary embodiment of the detector 110 according to the present invention, for determining a position of the at least one object 112. In this particular embodiment, the detector 110 may comprise one or more illumination sources 192, which may include an ambient light source and/or an artificial light source, and/or may comprise one or more reflective elements which may, for example, be connected to the object 112 for reflecting one or more primary light beams 206, as indicated in Fig. 1B. In addition or alternatively, the light beam 138 which emerges from the object 112 can fully or partially be generated by the object 112 itself, for example in the form of a luminescent radiation.

The optical sensors 114 comprise at least one transversal optical sensor 130 and, in this embodiment, a plurality of longitudinal optical sensors 132. The longitudinal optical sensors 132 form a longitudinal optical sensor stack 134. In the embodiment shown in Fig. 1B, five longitudinal optical sensors 132 are depicted, wherein the last longitudinal optical sensor 144 comprises a single longitudinal optical sensor 132 out of the plurality of the longitudinal optical sensors 132 within the longitudinal optical sensor stack 134 which faces away from the object 112. In this embodiment, it is particularly preferred to arrange the last longitudinal optical sensor 144 in the longitudinal optical sensor stack 134 in a manner that a light beam 138 first travels

through the plurality of the longitudinal optical sensors 132 within the longitudinal optical sensor stack 134 until it impinges the last longitudinal optical sensor 144.

5 The last longitudinal optical sensor 144 may be configured in various ways. Thus, the last longitudinal optical sensor 144 can for example be part of the detector 110 within the detector housing 118. Alternatively, the last longitudinal optical sensor 144 may be arranged outside the detector housing 118. It shall be emphasized that embodiments having a different number of longitudinal optical sensors 132 within the longitudinal optical sensor stack 134 are feasible.

10 Whereas the plurality of the longitudinal optical sensors 132 within the longitudinal optical sensor stack 134 with the exception of the last longitudinal optical sensor 144 preferably are at least partially transparent, particularly to enabling a high relative intensity at each of these longitudinal optical sensors 132, the last longitudinal optical sensor 144 may either be transparent or intransparent. In case the last longitudinal optical sensor 144 is transparent, it
15 may be feasible to further place an additional optical sensor behind the longitudinal optical sensor stack 134, such as a separate imaging device 157 in a manner that a light beam 138 first travels through the plurality of the longitudinal optical sensors 132 including the last longitudinal optical sensor 144 until it impinges on the imaging device 157.

20 The imaging device 157 may be configured in various ways. Thus, the imaging device 157 can for example be part of the detector 110 within the detector housing 118. Alternatively, the imaging device 157 may be separately located outside the detector housing 118. The imaging device 157 may be fully or partially transparent or intransparent. The imaging device 157 may be or may comprise an organic imaging device or an inorganic imaging device. Preferably, the
25 imaging device 157 may comprise at least one matrix of pixels, wherein the matrix of pixels is particularly selected from the group consisting of: an inorganic semiconductor sensor device such as a CCD chip and/or a CMOS chip; an organic semiconductor sensor device. The imaging device signal may be transmitted by one or more imaging device signal leads 159 to at least one evaluation device 142 of the detector 110, which will be explained in further detail
30 below.

In a further preferred embodiment, at least two of the longitudinal optical sensors 132 exhibit a differing spectral sensitivity. Preferably, a last longitudinal optical sensor 144, which preferably is intransparent, is configured to absorb all over the spectral ranges of the at least two of the
35 longitudinal optical sensors have the differing spectral sensitivity. By way of example, the differing spectral sensitivity of at least two of the longitudinal optical sensors 132 varies over spectral range in a manner that the at least two of the longitudinal optical sensors 132 are sensitive to a specific color whereas the intransparent last longitudinal optical sensor 144 is adapted to be sensitive to all colors of the visible spectra range. In a specific embodiment, the
40 longitudinal optical sensors 132 with the exception of the last longitudinal optical sensor 144 are each sensitive to a different specific color with little overlap. This feature particularly allows reliably acquiring depth information for a colored object 112 irrespective of the specific color of

the object 112, for which information at least two of the longitudinal optical sensors 132 are required, as described above. This feature is realized by the fact that for each color, absorption of the light beam 118 always occurs at least in two of the longitudinal optical sensors 132, i.e. in the one of the longitudinal optical sensor 132 which is sensitive to the specific color of the object 112, as well as in the last longitudinal optical sensor 144 being sensitive to all colors.

With respect to the other features as presented in an exemplary fashion in Fig. 1B, reference is made to the above description of Fig. 1A.

A further exemplary embodiment of the detector 110 according to the present invention is shown in Fig. 1C in a highly schematic manner. In this particular embodiment, the detector 110 may comprise one or more optically sensitive elements 161 which may particularly be placed along the optical axis 116 of the detector 110. As depicted herein, the optically sensitive element 161 may preferably be located between the transfer device 120, which here comprises one lens 122, and the optical sensor 114, which, in this embodiment, comprises at least one transversal optical sensor 130 and a plurality of longitudinal optical sensors 132 forming a longitudinal optical sensor stack 134. The optically sensitive element 161 may be configured in a number of ways, such as a wavelength-sensitive element, a phase-sensitive element, or a polarization-sensitive element.

As a non-limiting example, a wavelength-sensitive element comprising a color wheel 163 may be employed here as the optically sensitive element 161. Alternative wavelength-sensitive elements may comprise one or more of a prism, a grating, and/or a dichroitic mirror. The color-wheel 163 may especially comprise a circle around which at least two, preferably two to eight, separate segments are arranged which may differ from each other by their optical effect, particularly a grade of transmission, to the impinging light beam 138. Herein, the separate segments may each act as a filter which may allow determining a contribution of the colors red (R), green (G), and blue (B), also designated as "RGB color wheel". Alternatively, the color wheel 163 commonly designated as a "RGB-W color wheel" and additionally comprising a white (W) segment may be employed. As a further alternative, the color wheel 163 may comprise clear or transparent segments which may be used to increase luminous efficiency. Furthermore, the color wheel 163 may, alternatively or additionally, comprise one or more of the colors cyan, yellow, and magenta. A further alternative may comprise a so-called "color drum", wherein the segments are arranged on the inner surface of a drum where the incident light beam may be directed through in order to impinge an optical sensor.

Moreover, a sequential color recapture wheel (SCR wheel) may be generated from RGB dichroic coatings arranged in an Archimedes spiral pattern. Herein, the Archimedes spiral may exhibit the property that the boundaries between two segments may move at a constant speed in radial direction. Furthermore, it may be possible to include also here white or clear segments. Further examples for rotating color wheels, such as known from video beamer devices, and for color drums may be found under the address www.hcinema.de/farbrad.htm.

With respect to the other features as presented in an exemplary fashion in Fig. 1C, reference is made to the above descriptions concerning Figs. 1A and/or 1B.

5 In Figs. 2A and 2B, different views of a potential embodiment of a transversal optical sensor 130 are depicted. Therein, Fig. 2A shows a top-view on a layer setup of the transversal optical sensor 130, whereas Fig. 2B shows a partial cross-sectional view of the layer setup in a schematic setup. For alternative embodiments of the layer setup, reference may be made to the disclosure above.

10

The transversal optical sensor 130 comprises a transparent substrate 158, such as a substrate made of glass and/or a transparent plastic material. The setup further comprises a first electrode 160, an optical blocking layer 162, at least one n-semiconducting metal oxide 164, sensitized with at least one dye 166, at least one p-semiconducting organic material 168 and at least one second electrode 170. These elements are depicted in Fig. 2B. The setup may further comprise at least one encapsulation 172 which is not depicted in Fig. 2B and which is symbolically depicted in the top-view of Fig. 2A, which may cover a sensor region 136 of the transversal optical sensor 130.

15

20 As an exemplary embodiment, the substrate 158 may be made of glass, the first electrode 160 may fully or partially be made of fluorine-doped tin oxide (FTO), the blocking layer 162 may be made of dense titanium dioxide (TiO₂), the n-semiconducting metal oxide 164 may be made of nonporous titanium dioxide, the p-semiconducting organic material 168 may be made of spiro-MiOTAD, and the second electrode 170 may comprise PEDOT:PSS. Further, dye ID504, as e.g. disclosed in WO 2012/110924 A1, may be used. Other embodiments are feasible.

25

As depicted in Figs. 2A and 2B, the first electrode 160 may be a large-area electrode, which may be contacted by a single electrode contact 174. As depicted in the top-view in Fig. 2A, the electrode contacts 174 of the first electrode 160 may be located in corners of the transversal optical sensor 130. By providing more than one electrode contact 174, a redundancy may be generated, and resistive losses over the first electrode 160 might be eliminated, thereby generating a common signal for the first electrode 160.

30

Contrarily, the second electrode 170 comprises at least two partial electrodes 176. As can be seen in the top-view in Fig. 2A, the second electrode 170 may comprise at least two partial electrodes 178 for an x-direction, and at least two partial electrodes 180 for a y-direction via contact leads 182, these partial electrodes 176 may be contacted electrically through the encapsulation 172.

35

40 The partial electrodes 176, in this specific embodiment, form a frame which surrounds the sensor region 136. As an example, a rectangular or, more preferably, a square frame may be formed. By using appropriate current measurement devices, electrode currents through the

partial electrodes 176 may be determined individually, such as by current measurement devices implemented into the evaluation device 142. By comparing e.g. electrode currents through the two single x-partial electrodes 178, and by comparing the electrode currents through the individual y-partial electrodes 180, x- and y-coordinates of a light spot 184 generated by the light beam 138 in the sensor region 136 may be determined, as for the outlined with respect to Figs. 3A to 3D below.

In Figs. 3A to 3D, two different situations of a positioning of the object 112 are depicted. Thus, Fig. 3A and Fig. 3B show a situation in which the object 112 is located on the optical axis 116 of the detector 110. Therein, Fig. 3A shows a side-view and Fig. 3B shows a top-view onto the sensor region 136 of the transversal optical sensor 130. The longitudinal optical sensors 132 are not depicted in this setup.

In Fig. 3C and 3D, the setup of Figs. 3A and 3B is depicted in analogous views with the object 112 shifted in a transversal direction, to an off-axis position.

It shall be noted that, in Figs. 3A and 3C, the object 112 is depicted as the source of one or more light beams 138. As will be outlined in further detail below, specifically with respect the embodiment in Fig. 6, the detector 110 may as well comprise one or more illumination sources which may be connected to the object 112 and, thus, which may emit the light beams 138, and/or which might be adapted to illuminate the object 112 and, by the object 112 reflecting primary light beams, generate the light beams 138 by reflection and/or diffusion.

According to well-known imaging equations, the object 112 is imaged onto the sensor region 136 of the transversal optical sensor 130, thereby generating an image 186 of the object 112 on the sensor region 136, which, in the following, will be considered a light spot 184 and/or a plurality of light spots 184.

As can be seen in the partial images 3B and 3D, the light spot 184 on the sensor region 136 will lead, by generating charges in the layer setup of the sDSC, electrode currents, which, in each case, are denoted by i_1 to i_4 . Therein, electrode currents i_1, i_2 denote electrode currents through partial electrodes 180 in y-direction and electrode currents i_3, i_4 denote electrode currents through partial electrodes 178 in x-direction. These electrode currents may be measured by one or more appropriate electrode measurement devices simultaneously or sequentially. By evaluating these electrode currents, x- and y-coordinates may be determined. Thus, the following equations may be used:

$$x_0 = f\left(\frac{i_3 - i_4}{i_3 + i_4}\right) \text{ and } y_0 = f\left(\frac{i_1 - i_2}{i_1 + i_2}\right).$$

Therein, f might be an arbitrary known function, such as a simple multiplication of the quotient of the currents with a known stretch factor and/or an addition of an offset. Thus, generally, the

electrode currents i_1 to i_4 might form transversal sensor signals generated by the transversal optical sensor 130, whereas the evaluation device 142 might be adapted to generate information on a transversal position, such as at least one x-coordinate and/or at least one y-coordinate, by transforming the transversal sensor signals by using a predetermined or determinable transformation algorithm and/or a known relationship.

In Figs. 4A to 4C, various views of longitudinal optical sensors 132 are shown. Therein, Fig. 4A shows a cross-sectional view of a potential layer setup, and Figs. 4B and 4C show top-view of two embodiments of potential longitudinal optical sensors 132. Therein, Fig. 4C shows a potential embodiment of the last longitudinal optical sensor 144, wherein Fig. 4B shows potential embodiments of the remaining longitudinal optical sensors 132 of the longitudinal optical sensor stack 134. Thus, the embodiment in Fig. 4B may form a transparent longitudinal optical sensor 132, whereas the embodiment in Fig. 4C may be an intransparent longitudinal optical sensor 132. Other embodiments are feasible. Thus, the last longitudinal optical sensor 144, alternatively, might also be embodied as a transparent longitudinal optical sensor 132.

As can be seen in the schematic cross-sectional view in Fig. 4A, the longitudinal optical sensor 132 again, might be embodied as an organic photo-detector, preferably as an sDSC. Thus, similarly to the setup of Fig. 2B, a layer setup using a substrate 158, a first electrode 160, a blocking layer 162, an n-semiconducting metal oxide 164 being sensitized with a dye 166, a p-semiconducting organic material 168 and a second electrode 170 may be used. Additionally, an encapsulation 172 may be provided. For potential materials of the layers, reference may be made to Fig. 2B above. Additionally or alternatively, other types of materials may be used.

It shall be noted that, in Fig. 2B, an illumination from the top is symbolically depicted, i.e. an illumination by the light beam 138 from the side of the second electrode 170. Alternatively, an illumination from the bottom, i.e. from the side of the substrate 158 and through the substrate 158, may be used. The same holds true for the setup of Fig. 4A.

However, as depicted in Fig. 4A, in a preferred orientation of the longitudinal optical sensor 132, an illumination by the light beam 138 preferably takes place from the bottom, i.e. through the transparent substrate 158. This is due to the fact that the first electrode 160 may easily be embodied as a transparent electrode, such as by using a transparent conductive oxide, such as FTO. The second electrode 170, as will be outlined in further detail below may either be transparent or, specifically, for the last longitudinal optical sensor 144, intransparent.

In Fig. 4B and Fig. 4C, different setups of the second electrode 170 are depicted. Therein, in Fig. 4B, corresponding to the cross-sectional view of Fig. 4A, the first electrode 160 may be contacted by one or more electrode contacts 174, which, as an example, may comprise one or more metal pads, similar to the setup in Fig. 2B. These electrode contacts 174 may be located in the corners of the substrate 158. Other embodiments are feasible.

The second electrode 170, however, in the setup of Fig. 4B may comprise one or more layers of a transparent electrically conductive polymer 188. As an example, similar to the setup of Figs. 2A and 2B, PEDOT:PSS may be used. Further, one or more top contacts 190 may be provided, which may be made of a metallic material, such as aluminum and/or silver. By using one or
5 more contact leads 182, leading through the encapsulation 172, this top contact 190 may be electrically contacted.

In the exemplary embodiment shown in Fig. 4B, the top contact 190 forms a closed opened frame surrounding the sensor region 136. Thus, as opposed to the partial electrodes 176 in
10 Figs. 2A and 2B, only one top contact 190 is required. However, the longitudinal optical sensor 132 and the transversal optical sensor 130 may be combined in one single device, such as by providing partial electrodes in the setup of Figs. 4A to 4C. Thus, in addition to the FiP effect which will be outlined in further detail below, transversal sensor signals may be generated with the longitudinal optical sensor 132. Thereby, a combined transversal and longitudinal optical
15 sensor may be provided.

The use of the transparent electrically conductive polymer 188 allows for an embodiment of the longitudinal optical sensor 132 in which both the first electrode 160 and the second electrode 170 are at least partially transparent. The same, preferably, holds true for the transversal optical
20 sensor 130. In Fig. 4C, however, a setup of the longitudinal optical sensor 132 is disclosed which uses an intransparent second electrode 170. Thus, as an example, the second electrode 170 may be embodied by using one or more metal layers, such as aluminum and/or silver, instead of or in addition to the at least one electrically conductive polymer 188. Thus, as an example, the electrically conductive polymer 188 may be replaced or may be reinforced by one
25 or more metal layers which, preferably, may cover the full sensor region 136.

In Figs. 5A to 5E, the above-mentioned FiP effect shall be explained. Therein, Fig. 5A shows a side-view of a part of a detector 110, in a plain parallel to the optical axis 116, similar to the setup in Figs. 1, 3A and 3C. Of the detector 110, only the longitudinal optical sensors 132 and
30 the transfer device 120 are depicted. Not shown is at least one transversal optical sensor 130. This transversal optical sensor 130 may be embodied as a separate optical sensor 114 and/or may be combined with one or more of the longitudinal optical sensors 132.

Again, the measurement starts with an emission and/or reflection of one or more light beams
35 138 by at least one object 112. The object 112 may comprise an illumination source 192, which may be considered as a part of the detector 110. Additionally or alternatively, a separate illumination source 192 may be used.

Due to a characteristic of the light beam 138 itself and/or due to beam shaping characteristics of
40 the transfer device 120, preferably of the at least one lens 122, the beam properties of the light beam 138 in the region of the longitudinal optical sensors 132 at least partially are known. Thus,

as depicted in Fig. 5A, one or more focal points 194 might occur. In the focal point 194, a beam waist or a cross-section of the light beam 138 may assume a minimum value.

In Fig. 5B, in a top-view onto the sensor regions 136 of the longitudinal optical sensors 132 in Fig. 5A, a development of the light spots 184 generated by the light beam 138 impinging on the sensor regions 136 is depicted. As can be seen, close to the focal point 194, the cross-section of the light spot 184 assumes a minimum value.

In Fig. 5C, a photo current I of the longitudinal optical sensors 132 is given for the five cross-sections of the light spot 184 in Fig. 5B, in case longitudinal optical sensors 132 exhibiting the above-mentioned FiP effect are used. Thus, as an exemplary embodiment, five different photo currents I for the spot cross-sections as shown in Figs. 5B are shown for typical DSC devices preferably sDSC devices. The photo current I is depicted as a function of the area A of the light spot 184, which is a measure of the cross-section of the light spots 184.

As can be seen in Fig. 5C, the photo current I , even if all longitudinal optical sensors 132 are illuminated with the same total power of the illumination, the photo current I is dependent on the cross-section of the light beam 138, such as by providing a strong dependency on the cross-sectional area A and/or the beam waist of the light spot 184. Thus, the photo current is a function both of the power of the light beam 138 and of the cross-section of the light beam 138:

$$I=f(n,a).$$

Therein, I denotes the photo current provided by each longitudinal optical sensor 132, such as a photo current measured in arbitrary units, as a voltage over at least one measurement resistor and/or in amps. n denotes the overall number of photons impinging on the sensor region 136 and/or the overall power of the light beam in the sensor region 136. A denotes the beam cross-section of the light beam 138, provided in arbitrary units, as a beam waist, as a beam diameter of beam radius or as an area of the light spot 134. As an example, the beam cross-section may be calculated by the $1/e^2$ diameter of the light spot 184, i.e. a cross-sectional distance from a first point on a first side of a maximum intensity having an intensity of $1/e^2$ as compared to the maximum intensity of the light spot 184, to a point on the other side of the maximum having the same intensity. Other options of quantifying the beam cross-section are feasible.

The setup in Fig. 5C shows the photo current of a longitudinal optical sensor 132 according to the present invention which may be used in the detector 110 according to the present invention, showing the above-mentioned FiP effect. Contrarily, Fig. 5D in a diagram corresponding to the diagram of Fig. 5C, photo currents of traditional optical sensors are shown, for the same setup as depicted in Fig. 5A. As an example, silicon photo detectors may be used for this measurement. As can be seen, in these traditional measurements, the photo current or photo signal of the detectors is independent from the beam cross-section A .

Thus, by evaluating the photo currents and/or other types of longitudinal sensor signals of the longitudinal optical sensors 132 of the detector 110, the light beam 138 may be characterized. Since the optical characteristics of the light beam 138 depend on the distance of the object 112 from the detector 110, by evaluating these longitudinal sensor signals, a position of the object
 5 112 along the optical axis 116, i.e. a z-position, may be determined. For this purpose, the photo currents of the longitudinal optical sensors 132 may be transformed, such as by using one or more known relationships between the photo current I and the position of the object 112, into at least one item of information on a longitudinal position of the object 112, i.e. a z-position. Thus, as an example, the position of the focal point 194 may be determined by evaluating the sensor
 10 signals, and a correlation between the focal point 194 and a position of the object 112 in the z-direction may be used for generating the above-mentioned information. Additionally or alternatively, a widening and/or narrowing of the light beam 138 may be evaluated by comparing the sensor signals of the longitudinal sensors 132. As an example, known beam properties may be assumed, such as a beam propagation of the light beam 138 according to
 15 Gaussian laws, using one or more Gaussian beam parameters.

Further, the use of a plurality of longitudinal optical sensors 132 provides additional advantages as opposed to the use of a single longitudinal optical sensor 132. Thus, as outlined above, the overall power of the light beam 138 generally might be unknown. By normalizing the longitudinal
 20 sensor signals, such as to a maximum value, the longitudinal sensor signals might be rendered independent from the overall power of the light beam 138, and a relationship

$$I_n = g(A)$$

25 may be used by using normalized photo currents and/or normalized longitudinal sensor signals, which is independent from the overall power of the light beam 138.

Additionally, by using the plurality of longitudinal optical sensors 132, an ambiguity of the longitudinal sensor signals may be resolved. Thus, as can be seen by comparing the first and
 30 the last image in Fig. 5B and/or by comparing the second and the fourth image in Fig. 5B, and/or by comparing the corresponding photo currents in Fig. 5C, longitudinal optical sensors 132 being positioned at a specific distance before or behind the focal point 194 may lead to the same longitudinal sensor signals. A similar ambiguity might arise in case the light beam 138 weakens during propagations along the optical axis 116, which might generally be corrected
 35 empirically and/or by calculation. In order to resolve this ambiguity in the z-position, the plurality of longitudinal sensor signals clearly shows the position of the focal point and of the maximum. Thus, by e.g. comparing with one or more neighboring longitudinal sensor signals, it may be determined whether a specific longitudinal optical sensor 132 is located before or beyond a focal point on the longitudinal axis.

40

In Figure 5E, a longitudinal sensor signal for a typical example of an sDSC is depicted, in order to demonstrate the possibility of the longitudinal sensor signal and the above-mentioned FiP

effect being dependent on a modulation frequency. In this figure, a short-circuit current I_{sc} is given as the longitudinal sensor signal on the vertical axis, in arbitrary units, for a variety of modulation frequencies f . On the horizontal axis, a longitudinal coordinate z is depicted. The longitudinal coordinate z , given in micrometers, is chosen such that a position of a focus of the light beam on the z -axis is denoted by position 0, such that all longitudinal coordinates z on the horizontal axis are given as a distance to the focal point of the light beam. Consequently, since the beam cross-section of the light beam depends on the distance from the focal point, the longitudinal coordinate in Figure 5E denotes the beam cross-section in arbitrary units. As an example, a Gaussian light beam may be assumed, with known or determinable beam parameters, in order to transform the longitudinal coordinate into a specific beam waist or beam cross-section.

In this experiment, longitudinal sensor signals are provided for a variety of modulation frequencies of the light beam, for 0 Hz (no modulation), 7 Hz, 377 Hz and 777 Hz. As can be seen in the figure, for modulation frequency 0Hz, no FiP effect or only a very small FiP effect, which may not easily be distinguished from the noise of the longitudinal sensor signal, may be detected. For higher modulation frequencies, a pronounced dependency of the longitudinal sensor signal on the cross section of the light beam may be observed. Typically, modulation frequencies in the range of 0.1 Hz to 10 kHz may be used for the detector according to the present invention, such as modulation frequencies of 0.3 Hz.

Human-machine interface, entertainment device and tracking system:

In Fig. 6, an exemplary embodiment of a human-machine interface 196 according to the invention, which can simultaneously also be embodied as an exemplary embodiment of an entertainment device 198 according to the invention or which can be a constituent part of such an entertainment device 198, is depicted. Further, the human-machine interface 196 and/or the entertainment device 198 may also form an exemplary embodiment of a tracking system 199 adapted for tracking a user 200 and/or one or more body parts of the user 200. Thus, a motion of one or more of the body parts of the user 200 may be tracked.

By way of example, at least one detector 110, according to the present invention can once again be provided, for example, in accordance with one or more of the embodiments described above, with one or a plurality of optical sensors 114, which may comprise one or more transversal optical sensors 130 and one or more longitudinal optical sensors 132. Further elements of the detector 110 can be provided, which are not illustrated in Fig. 6, such as, for example, elements of an optional transfer device 120. For a potential embodiment, reference may be made to Fig. 1A and/or B. Furthermore, one or a plurality of illumination sources 192 may be provided. Generally, with regard to these possible embodiments of the detector 110, reference can be made for example to the description above.

The human-machine interface 196 can be designed to enable an exchange of at least one item of information between a user 200 and a machine 202, which is merely indicated in Fig. 6. For example, in exchange of control commands, and/or information may be performed by using the human-machine interface 196. The machine 202 can comprise, in principle, any desired device
5 having at least one function which can be controlled and/or influenced in some way. At least one evaluation device 142 of the at least one detector 110 and/or a part thereof can, as indicated in Fig. 6, be wholly or partially integrated into said machine 201, but can, in principle, also be formed fully or partially separately from the machine 202.

10 The human-machine interface 196 can be designed for example to generate, by means of the detector 110, at least one item of geometrical information of the user 200 by means of the detector 110 and can assign the geometrical information at least to one item of information, in particular at least one control command. For this purpose, by way of examples, by means of the detector 110, a movement and/or a change in posture of the user 200 can be identified. For
15 example, as indicated in Fig. 6, a hand movement and/or a specific hand posture of the user 200 may be detected. Additionally or alternatively, other types of geometrical information of the user 200 may be detected by the one or more detectors 110. For this purpose, one or more positions and/or one or more position information regarding the user 200 and/or one or more body parts of the user 200 may be identified by the at least one detector 110. It is then possible
20 to recognize, for example by comparison with a corresponding command list, that the user 200 would like to effect a specific input, for example would like to give the machine 202 a control command. As an alternative or an addition to direct diametrical information about the actual user 200, it is also possible, for example, to generate at least one item of geometrical
25 information about at least one beacon device 204 attached to the user 200, such as at least one item of geometrical information about a garment of the user 200 and/or a glove and/or an article moved by the user 200, such as a stick, a bat, a club, a racket, a cane, a toy, such as a toy gun. One or more beacon devices 204 may be used. The beacon device 204 may be embodied as an active beacon device and/or as a passive beacon device. Thus, the beacon device 204 may
30 comprise one or more illumination sources 192 and/or may comprise one or more reflective elements for reflecting one or more primary light beams 206, as indicated in Fig. 6.

The machine 202 can furthermore comprise one or a plurality of further human-machine interfaces, which need not necessarily be embodied according to the invention, for example, as indicated in Fig. 6, at least one display 208 and/or at least one keyboard 210. Additionally or
35 alternatively, other types of human-machine interfaces may be provided. The machine 202 can, in principle, be any desired type of machine or combination of machines, such as a personal computer.

40 The at least one evaluation device 142 and/or parts thereof may further function as a track controller 201 of the tracking system 199. Additionally or alternatively, one or more additional track controllers 201 may be provided, such as one or more additional data evaluation devices. The track controller 201 may be or may comprise one or more data memories, such as one or

more volatile and/or non-volatile memories. In this at least one data memory, a plurality of subsequent positions and/or orientation of one or more objects of parts of an object may be stored, in order to allow for storing a past trajectory. Additionally or alternatively, a future trajectory of the object and/or parts thereof may be predicted, such as by calculation, extrapolation or any other suitable algorithm. As an example, a past trajectory of an object or a part thereof may be extrapolated to future values, in order to predict at least one of a future position, a future orientation and a future trajectory of the object or a part thereof.

In the context of an entertainment device 198, said machine 202 can be designed for example to carry out at least one entertainment function, for example at least one game, in particular with at least one graphical display on the display 208 and, optionally, a corresponding audio output. The user 200 can input at least one item of information, for example via the human-machine interface 196 and/or one or more other interfaces, wherein the entertainment device 198 is designed to alter the entertainment function in accordance with the information. By way of example, specific movements or one or more virtual articles, for example of virtual persons in a game and/or movements of virtual vehicles in a game, may be controlled by means of corresponding movements of the user 200 and/or one or more body parts of the user 200, which, in turn, may be recognized by the detector 110. Other types of control of at least one entertainment function by the user 200, by means of the at least one detector 110, are also possible.

Exemplary embodiments of sDSCs for a 3-D position sensor:

The practical implementation of the FiP-effect of the sDSCs in the form of a 3-D sensor, and achieving good spatial resolution both in the x,y- and in the z-direction, typically may require the cells to have an active area of approximately 1 cm x 1 cm and meet certain requirements. Therefore, in the following, preferred requirements for the individual cells of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor are given. It shall be noted, however, that other embodiments are feasible.

Optical properties of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor:

As can be seen in Figures 5A to 5C, one particular current signal can imply two different spatial points (in front and behind the focus). In order to obtain unambiguous depth information on the z-axis, therefore, preferably at least two cells need to be arranged one behind the other. Unambiguous information is then derived from the ratio between the current signals of the two cells. For the sake of precise z-information, this sensor should have six cells stacked behind each other. This requires the cells to be transparent, i.e. the back electrode that normally consists of vapor-deposited silver across its entire area needs to be replaced by a transparent conducting material.

To ensure that sufficient illumination reaches the last cell and it supplies a useful current signal, the front five cells may have only low absorption at the excitation wavelength. The wavelength used for excitation should be around 700 nm.

5 Cross-resistance of the transversal optical sensors:

To achieve precise x,y resolution, there has to be a sufficient potential difference between each pair of opposite sides in this square cell. Fig. 2A shows such a transparent cell with which the x,y resolution is possible.

10

Even without a silver back electrode, sufficiently good electron transport from the p-type conductor into the oxidized dye has to be ensured across the entire surface area of the cells so that the dye is regenerated rapidly by a supply of electrons. Since the p-type conductor itself has very low conductance (10^{-5} S/cm), a conducting layer needs to be coated onto the p-type

15 conductor. Thanks to this additional layer, a defined cross-resistance R is to be achieved between the opposite sides of this square cell.

Transparency of the transversal optical sensors:

20 Due to their good conductance, normal solar cells have back electrodes (second electrodes) made of silver. The cells being developed here, however, have to be transparent, which is why the 1 cm² cell area typically requires a transparent back electrode. The material preferably used for this purpose is the conducting polymer poly(3,4-ethylenedioxythiophene)-poly(styrenesulfonate) (PEDOT:PSS) in aqueous dispersion. The conjugated polymer

25 PEDOT:PSS is highly transparent; it absorbs in the blue-green region (450-550 nm) only at considerable layer thicknesses, and only minimally in the red spectral range.

The additional PEDOT layer makes possible good electron transport in the p-type conductor. To improve the conductance of this layer and provide contacts, four silver electrodes 1 cm in length

30 are vapor-deposited around the square cell. The arrangement of the silver electrodes is shown in Fig. 3.3a. Fig. 3.3b shows a cell with a transparent PEDOT back electrode.

Extinction of the cells of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor:

35

It is not only the back electrode that has to be transparent, but the entire cell. To ensure that a sufficient amount of light still reaches the last cell in the stack, the extinction of the front five cells should be as low as possible. This is determined first and foremost by the dye's absorption. The extinction of a solar cell, i.e. the absorption of light by the dye, has a decisive

40 effect on the cell's output current. Typically, the wavelength-dependent absorption spectrum has a maximum – the wavelength of maximum absorption is characteristic of the particular dye used. The more dye has been adsorbed in the np TiO₂ layer, the higher the cell's absorption.

The more dye molecules are adsorbed, the more electrons can reach the cb of the TiO₂ through optical excitation and the higher the current. A cell with higher extinction will, therefore, have a higher output current than one with low extinction.

- 5 The objective here is to obtain the maximum total current from the complete cell arrangement – which in the ideal case is divided equally among all the cells. Since the intensity of the light is attenuated by absorption in the cells, the ones located further back in the stack receive less and less light. In order, nonetheless, to obtain similar output currents from all six cells, it would make sense for the front cells to have lower extinction than the ones at the back. As a result, they will
- 10 stop less of the light reaching the following cells, which in turn will absorb a larger proportion of the already weakened light. Through optimal adjustment of the extinctions at the positions of the cells in the stack, in this way theoretically one could obtain the same current from all the cells. The extinction of a solar cell can be adjusted by staining with a dye and by controlling the thickness of the np TiO₂ layer.

15

Optimizing the extinction and the output current of the cells of the longitudinal optical sensor stack:

- The last cell in the stack preferably should absorb almost all the incident light. For this reason,
- 20 this cell should have maximum extinction. Starting with the current obtained under maximum extinction at the last cell, the extinctions of the front cells need to be so adjusted that all cells together supply a maximum total current, one that is distributed as uniformly as possible across all the cells.

- 25 Optimizing the stack's output currents is carried out as follows:

- The choice of dye
- Maximum extinction/maximum output current of the last cell
- Dye concentration for staining the last cell

30

- Staining time of the last cell
- Optimum thickness of the last cell's np TiO₂ layer
- Maximum output current of the complete stack
- Optimum thickness of the np TiO₂ layers of the front five cells

- 35 The extinction was measured with a Zeiss spectrometer MCS 501 UV-NIR using Zeiss lamp MCS 500. The results were evaluated with an Aspect Plus software program.

Choice of dye:

- 40 To begin with, a dye should be found that absorbs sufficiently at the excitation wavelength of approximately 700 nm. The ideal dye for solar cells typically has a broad absorption spectrum and should absorb completely the incident light below a wavelength of ca. 920 nm. In actual

fact, most dyes have an absorption maximum in the wavelength range between 450-600 nm; above 650 nm they usually absorb weakly or not at all.

5 The dye with which the first experiments were performed was ID504, as e.g. disclosed in WO 2012/110924 A1. This dye, however, turned out to exhibit only a low absorption in the range of 700 nm. Therefore, for the stack, the dye D-5 (also referred to as ID 1338) was used:

10 Preparation and properties of the Dye D-5 are disclosed in WO 2013/144177 A1.

Additionally or alternatively, however, other dyes may be used. The staining time, i.e. the duration of staining of the TiO₂-layer with the respective dye, turned out to have an influence on the absorption properties. The tests were performed with cells having np TiO₂ layers having a thickness of 1.3 microns. The absorption maximum of D-5 is around 550-560 nm which exhibits
15 an extinction $\epsilon \approx 59000$ at this maximum.

In this experimental series, the dye concentration was 0.3 mM and the staining time was increased so as to be 10 to 30 minutes. A pronounced increase in extinction at longer staining
20 times was observed, so finally staining times of 30 min. were used for D-5.

Still, even after optimizing the staining time, the absorption was determined to be rather very low. Therefore, generally, the absorption will have to be maximized by increasing the dye concentration, the staining time and the thickness of the np TiO₂ layer.

25

Dye concentration and staining time of the last cell in the longitudinal optical sensor stack:

Several experiments regarding the staining time and the dye concentration were performed. The standard concentration of the dye solution for a layer thickness of the TiO₂-layers of 1-2
30 microns was 0.5 mM. At these concentrations, the dye should already be present in excess. Here the dye concentration was increased to 0.7 mM. In order to prevent inhomogeneities across the cell's area, the dye solution was cleaned by removing undissolved dye particles and other impurities, using a 0.2 micron syringe filter, before placing the cells in it.

35 If the dye is present in excess, then after a 1 hour staining time a dye monolayer dye should have been adsorbed to the surface of the np TiO₂ layer, which leads to maximum absorption by

the dye being used. The maximum staining time tested here was 75 minutes, which was finally used for the cells.

Finally, cells having a layer thickness of the TiO₂-layer of 1.3 microns, a dye concentration of 0.7 mM and a staining time of 75 min was used. The cell's extinction turned out to be 0.4 at 700 nm.

The np TiO₂ layer thickness of the last cell of the longitudinal optical sensor stack:

Ultimately, the thickness of the nanoporous (np) layer and thus the TiO₂ surface area available for dye adsorption may be an important factor influencing the absorption behavior and therefore the cells' output current. So far, maximizing the extinction was done in cells with np TiO₂ layers whose thickness was 1.3 microns. Since more dye can be adsorbed in thicker np TiO₂ layers, the thickness of the TiO₂ layer was increased in steps to 3 microns, and the thickness at which the greatest output current occurred was determined.

The nanoporous TiO₂ layers were applied by spin coating. Spin coating is suitable for applying low-volatility substances dissolved in a high-volatility solvent (here: terpineol). As a starting product, TiO₂ paste made by Dyesol (DSL 18 NR-T) was used. This paste was mixed with terpineol, which decreases the viscosity of the paste. Depending on the composition ratio of the paste : terpineol mixture, and at a constant spin velocity of 4500 1/min, np TiO₂ layers of varying thicknesses are obtained. The higher the terpineol proportion, the lower the viscosity of the diluted paste and the thinner the cells will be.

The diluted TiO₂ paste was also cleaned using a 1.2 micron syringe filter to remove larger particles, before applying the paste the next day by spin coating on the cells coated with blocking layer.

When varying the np TiO₂ layer thickness, it should be noted that the concentration of the p-type conductor dissolved in chlorobenzene needs to be adjusted. Thicker np layers have a larger cavity volume that has to be filled with p-type conductor. For this reason, in the case of thicker np layers the amount of supernatant p-type conductor solution on top of the np layer is smaller. To ensure that the solid p-type conductor layer remaining on the np TiO₂ layer after spin coating has a constant thickness (the solvent evaporates during spin coating), higher p-type conductor concentrations are needed for thick np TiO₂ layers than for thin ones. The optimal p-type conductor concentrations are not known for all the TiO₂ layer thicknesses tested here. For this reason, the p-type conductor concentration is varied for the unknown layer thicknesses and the output currents compared for equal layer thicknesses but different p-type conductor concentrations.

The chosen starting value for the layer thickness variation was a 1.3 microns for the np TiO₂ layer. 1.3 microns corresponds to a TiO₂ paste : terpineol mass composition of 5 g : 5 g. A test

series with cells whose np TiO₂ layers are thicker than 1.3 microns will show at which layer thickness the largest output current is obtained from the last cell in the stack.

5 These cells were stained with the aforementioned optimized parameters for maximum extinction (D-5; c = 0.7 mM; staining time: 75 minutes). The extinction of these cells was found to be approximately 0.6 at 700 nm.

10 Since the last cell generally does not have to be transparent, the back electrode was vapor-deposited on the whole 1 cm² area directly onto the p-type conductor – without PEDOT.

The measurement results indicated that, as expected, the output currents of the cells with a whole-area back electrode (second electrode) are much higher. Highest output currents were obtained with a TiO₂ : terpineol mass ratio of 5 : 3. This corresponds to a TiO₂ layer thickness of 2-3 microns.

15 Therefore, in subsequent experiments, a TiO₂ paste : terpineol composition of 5 : 3 was used for the last cell in the stack. The back electrode was vapor-deposited across the entire 1 cm² cell area.

20 The np TiO₂ layer thickness of the front cells of the longitudinal optical sensor stack:

Starting from the maximum output current obtained with the last cell, the thicknesses of the front cells' np TiO₂ layers are to be so adjusted that every cell in the stack generates the maximum possible output current. This requires low extinction values in the front cells.

25 During the experiments, it turned out that, in practical terms, it is rather difficult to obtain reproducible low extinctions through the dye concentration and staining time parameters. In order to make cells with low, reproducible extinction, therefore, it makes sense to fabricate cells with thin np TiO₂ layers and to keep them in the dye solution for the time needed to ensure dye saturation of the np TiO₂ surface. The terpineol proportion in the TiO₂ layers was increased in a stepwise fashion. All the cells were stained under the same conditions. Since their extinction is intended to be decreased significantly, the dye concentration here was 0.5 mM, and the staining time was 60 minutes.

35 Surprisingly, in this series, the cell's output voltages turned out to begin with an increase in output current with decreasing np TiO₂ layer thickness. The optimum out of the tested TiO₂ paste dilutions turned out to be 5 : 6. At higher dilutions and therefore thinner np TiO₂ layers, the output current tends to decrease. The reason for the exception to this trend at a dilution of 5 : 9 is likely to be optimal adjustment of the p-type conductor concentration of 100 mg/ml for this layer thickness.

40

If, however, one considers the decrease in extinction relative to that of the output current, it makes sense to accept the lower output current in order to ensure that the following cells receive very much more light than would be the case with 5 : 6 dilution. Photographs of cells with TiO₂ : terpineol mixtures of 5 : 4.1, 5 : 6 and 5 : 10 were taken, which illustrated this effect.

- 5 Effects of inhomogeneity were observed. In order to achieve a homogeneous layer within a 1 cm² cell, the TiO₂ area was increased for later cells such that the region in which the TiO₂ banks up during spin coating lies outside the silver electrodes and thus outside the cell.

- 10 The construction of the cell stack with regard to the TiO₂ layer's thickness in the cells and their positioning in the stack, was carried out by testing various arrangements of cells with np TiO₂ layers of various thicknesses.

Preparation and the properties of a dye sensitized solar cell (DSC) prepared with the Dye D-5

- 15 FTO (tin oxide doped with fluorine) glass substrates (< 12 ohms/sq, A11DU80, supplied by AGC Fabritech Co., Ltd.) were used as the base material, which were successively treated with glass cleaner, Semico Clean (Furuuchi Chemical Corporation), fully deionized water and acetone, in each case for 5 min in an ultrasonic bath, then baked for 10 minutes in isopropanol and dried in a nitrogen flow.

- 20 A spray pyrolysis method was used to produce the solid TiO₂ buffer layer. Titanium oxide paste (PST-18NR, supplied by Catalysts & Chemicals Ind. Co., Ltd.) was applied onto the FTO glass substrate by screen printing method. After being dried for 5 minutes at 120°C, a working electrode layer having a thickness of 1.6 µm was obtained by applying heat treatment in air at 25 450°C for 30 minutes and 500°C for 30 minutes. Obtained working electrode is then treated with TiCl₄, as described by M. Grätzel et al., for example, in Grätzel M. et al., Adv. Mater. 2006, 18, 1202. After sintering the sample was cooled to 60 to 80°C. The sample was then treated with an additive as disclosed in WO 2012/001628 A1. 5 mM of the additive in ethanol was prepared and the intermediate was immersed for 17 hours, washed in a bath of pure ethanol, briefly dried in a 30 nitrogen stream and subsequently immersed in a 0.5 mM solution of dye D-5 in a mixture solvent of acetonitrile + t-butyl alcohol (1:1) for 2 hours so as to adsorb the dye. After removal from the solution, the specimen was subsequently washed in acetonitrile and dried in a nitrogen flow.

- 35 A p-type semiconductor solution was spin-coated on next. To this end a 0.165M 2,2',7,7'-tetrakis(N,N-di-p-methoxyphenyl-amine)-9,9'-spirobifluorene (spiro-MeOTAD) and 20mM LiN(SO₂CF₃)₂ (Wako Pure Chemical Industries, Ltd.) solution in chlorobenzene was employed. 20 µl/cm² of this solution was applied onto the specimen and allowed to act for 60 s. The supernatant solution was then spun off for 30 s at 2000 revolutions per minute. The substrate 40 was stored overnight under ambient conditions. Thus, the HTM was oxidized and for this reason the conductivity increased.

As the metal back electrode, Ag was evaporated by thermal metal evaporation in a vacuum at a rate of 0.5 nm/s in a pressure of 1×10^{-5} mbar, so that an approximately 100 nm thick Ag layer was obtained.

- 5 In order to determine the photo-electric power conversion efficiency η of the above photoelectric conversion device, the respective current/voltage characteristic such as short-circuit current density J_{sc} , open-circuit voltage V_{oc} and fill factor FF was obtained with a Source Meter Model 2400 (Keithley Instruments Inc.) under the illumination of an artificial sunlight (AM 1.5, 100 mW/cm² intensity) generated by a solar simulator (Peccell Technologies, Inc). As a result, the
- 10 DSC prepared with the Dye D-5 exhibited the following parameters:

J_{sc} [mA/cm ²]	V_{oc} [mV]	FF [%]	η [%]
10.5	721	59	4.5

Results of the optimized output currents for the longitudinal optical sensor stack:

- 15 The best result in terms of the cell stack's output currents were obtained when all five transparent cells of the longitudinal optical sensors step have an np TiO₂ layer thickness of 0.45 micrometers (i.e. a TiO₂ paste dilution of 5 : 10). These cells with a 0.45 micrometers np TiO₂ layer were stained for 60 minutes in a 0.5 mM dye solution. Only the last cell had a np TiO₂ layer just under 3 micrometers and was stained for 75 minutes (0.7 mM). Since the last cell
- 20 does not have to be transparent, the back electrode (second electrode) of the last cell was a vapor-deposited silver layer across the whole 1 cm² area so as to be able to pick up the maximum possible current. The following photo currents were observed with this stack, in order from the first cell to the last cell of the stack :

25 Current [μ A]: 37 9.7 7.6 4.0 1.6 1.9

- The first five cells were made identically. The last cell had a thicker np TiO₂ layer and a silver back electrode vapor-deposited across the whole cell area. One can see that the current of the second cell has already dropped to 1/4 of the first cell's. Even in these five highly transparent
- 30 cells, the last cell's current is only a fraction of the current in the first cell. The cells were excited with a red laser (690 nm, 1 mW) directed at the centre of the cell area.

- The current obtained with cells with a TiO₂ : terpineol dilution of 5 : 9, 5 : 8 or 5 : 7 (i.e. thicker cells) was at most 10 microamps larger than the current of a cell with 5 : 10 dilution of the TiO₂
- 35 paste. These cells, however, exhibited a significantly higher extinction, as a result of which the output current of the following cells decreases considerably.

- The cells with a TiO₂ dilution of 5 : 6, in which – compared with the TiO₂ dilutions of 5 : 9; 5 : 8 and 5 : 7 – a significantly higher current was obtained, nevertheless absorbed so much light that
- 40 no more light reaches the last cell of the stack. Even when placing just one of these cells in

position 5 with four preceding 450 nm thin cells, the output current of the last cell decreased considerably, such that the last cell supplies practically no more current.

It needs mentioning that each of these cells in the test stack was sealed with an additional glass plate for protection against ambient effects. This, however, created many additional interfaces at which the light beam of the 690 nm laser (1 mW) can be reflected and scattered, as a result of which the extinction of such a sealed cell is higher. In the later device the cell stack was kept in nitrogen, which is why the sealing becomes unnecessary and the cells lie directly on top of each other. This decreased the stack's extinction, since the losses resulting from scattering at the cover glasses no longer occur.

Cross-resistance of the transversal optical sensors:

A defined cross-resistance between the opposite sides of the square cell makes precise x,y resolution possible. The principle of x,y resolution is illustrated in Figures 3A to 3D. The cross-resistance across the area of the cell is determined by the PEDOT layer present between the p-type conductor and the silver electrodes bordering the cell. In the undoped state, PEDOT is a semiconductor. Conductivity is made possible by the system of conjugated double bonds extending across the entire molecule in combination with the doping with a negatively charged counter-ion. The PEDOTs used which were used for the present experiments were all doped with the negatively charged polymer polystyrene sulfonate (PSS). PEDOT:PSS is available in a wide range of embodiments as regards conductance, solid content, ionisation potential (IP), viscosity and pH.

Factors affecting the cross-resistance:

The PEDOT was also applied to the cells by spin coating. During the spinning process, the solvents ethanol and isopropanol evaporate whereas the low-volatility PEDOT remains on the substrate in the form of a film. The resistance of this layer depends on the conductance of the PEDOT being used and on the thickness of the layer:

$$R = \rho \cdot \frac{l}{A}$$

where ρ is the resistivity, l the distance across which the resistance is measured and A the cross-sectional area through which the charge carriers flow (A is a function of the PEDOT layer's thickness).

According to known principles of spin-coating, the layer thickness d to be expected when coating a non-Newtonian fluid can be determined by:

$$d = \sqrt[3]{\frac{3 \cdot x_s^3 \cdot u_k \cdot e}{2 \cdot (1 - x_s) \cdot \omega^2}}$$

$$\sim \sqrt[3]{\frac{x_s^3 \cdot u_k}{(1 - x_s) \cdot \omega^{3/2}}}$$

where x_s is the PEDOT percentage in the mixed diluted solution, u_k is the kinematic viscosity, e the evaporation rate of the solvent(s) and ω the angular velocity during spin coating. The evaporation rate is proportional to $\omega^{1/2}$.

The thickness of the PEDOT layer can, therefore, be affected by various parameters: the angular velocity, the viscosity of the PEDOT solution and the percentage of PEDOT in the solution. The angular velocity can be varied directly. The viscosity and the percentage of PEDOT in the solution can only be affected indirectly, i.e. via the ratio at which the PEDOT is mixed with ethanol and isopropanol.

The following parameters, therefore, can be used in order to adjust the cross-resistance, and they will be optimized in due course:

- The choice of PEDOT
- The layer thickness of the PEDOT
- The PEDOT/solvent ratio
- The spin speed during the PEDOT's spin coating
- The number of PEDOT layers
- The time interval Δt between applying and spin coating the PEDOT

Optimizing the cross-resistance:

The PEDOT solution was mixed with ethanol and isopropanol in a standard volumetric ratio of 1: 1 : 1, and larger particles removed with a 0.45 micrometer syringe filter. The entire cell was covered with this diluted PEDOT solution (approximately 900 microliters were needed per substrate) and spin coated at a speed of 2000 1/s. At this speed, 30 s turned out to suffice to remove and evaporate the solvents ethanol and isopropanol.

The aforementioned parameters were then varied systematically, with the objective of obtaining a cross-resistance of ca. 2 k Ω between the opposite electrodes of the square cell.

Choice of PEDOT:

The greatest impact on the PEDOT layer's cross-resistance turned out to come from the conductance of the PEDOT solution used. In order to obtain a first impression of the order of magnitude of the resistances of such a PEDOT layer across 1 cm, three PEDOT products with very different conductances were tested:

5

- Clevios™ PVP AI 4083 from Heraeus
- Clevios™ PH 1000 from Heraeus
- Orgacon™ N-1005 from Sigma Aldrich

10 The relevant parameters of dynamic viscosity η_d , ionisation potential IP and resistivity ρ are summarised in Table 1. The IP is an important selection criterion for the PEDOT. The PEDOT's IP generally should be less than 5 eV in order to ensure good functionality of the cell.

	AI 4083	PH 1000	N-1005
η_d [mPas]	5 - 12	15 - 50	7 - 12
IP [eV]	5.2	4.8	N/A
ρ [Ωcm]	500 - 5000	0.0012	75 - 120

15

Table 1: Relevant parameters for various PEDOTs.

For these first tests, 1.3 micrometer np TiO₂ layers were coated onto FTO-free glass substrates. In this first experimental series, only 300 microliters of each of the three prepared PEDOT solutions were coated directly on np TiO₂ layers – without the staining or p-type conductor coating steps. For each PEDOT solution, three substrates with 1, 2 and 3 PEDOT layers were made. The resistance was measured by applying a layer of conducting silver paint at 1 cm spacing at several positions on each substrate.

20

25 It is to be expected that the resistance of the substrate fabricated in this way, will be smaller than the resistance resulting from applying the PEDOT on a smooth p-type conductor layer.

As expected, the experiments showed a decrease in cross-resistance with an increasing number of layers and therefore increasing total thickness of the PEDOT. The cross-resistance of AI 4083 is in the M Ω range even with three layers, therefore it was not used in further tests. PH 1000 with two applied layers was in the required range. The cross-resistance of N 1005 is also in the k Ω range, and could be decreased through optimization. Since, however, it can be assumed that when applying the PEDOT on the smooth p-type conductor's surface the resistance will be higher than when applying it directly on the np TiO₂ layer as in this test series, further optimizations will focus on PH 1000.

30

35

Applying several PEDOT layers:

A further option for increasing the total thickness of the PEDOT layer is to apply several PEDOT layers consecutively. Tests were conducted with 1 and 2 applied PEDOT layers. PH 1000 was mixed with ethanol and isopropanol at a 1 : 1 : 1 volumetric ratio. The cells were covered completely with 900 microliters of the PEDOT solution and the excess solution was removed by spin coating at an RPM of 2000 1/min.

Unlike the first experimental series, these tests were conducted on 'complete' cells, i.e. stained cells coated with p-type conductor. The cross-resistance was measured between two circular vapour-deposited electrodes ca. 2 mm apart, in order to exclude errors resulting from different contact resistances of PEDOT/conducting silver paint and PEDOT/vapour-deposited silver. In addition, cell efficiency measurements can be automated with this electrode arrangement. These test cells are very much simpler and quicker to make than the square transparent ones, but they suffice for the requirements of these tests (for one thing, the cross-resistance of the PEDOT layer(s) is to be measured here across a defined section; for another, the cells are to be tested for functionality, i.e. whether there is good contact between the p-type conductor and the PEDOT and the IP of the PEDOT matches the energy level of the p-type conductor). The cross-resistance across 1 cm is calculated using equation 3.1 – assuming equal layer thickness and therefore equal area A – through multiplication by the factor 5 (the resistivity of the solution is constant).

Table 2 shows the results of the resistance measurement between the two circular vapor-deposited back electrodes and the calculated cross-resistances across 1 cm for 1 and 2 PEDOT layers. The last column shows the efficiency of the cells. The smallest and largest measurements obtained in several tests are shown in each case.

Mixture ratio	Number of layers	RPM [1/min]	$R_{l=2mm}$ [k Ω]	$R_{l=1cm}$ [k Ω]	η [%]
1 : 1 : 1	1	2000	6 - 19	30 - 90	1.5 - 2.5
	2		0.18 - 0.27	0.9 - 1.35	0.4 - 0.6

Table 2: Results of resistance measurements for one and two PEDOT layers.

The difference in cross-resistances between one and two applied PEDOT layers can be seen clearly. For one PEDOT layer it is significantly higher than the required 2 k Ω , for two layers it is very much lower. It is also evident, however, that the efficiency of the cells with two applied PEDOT layers is very much smaller, which means that the contact between the two PEDOT layers is poor. It should be noted that the efficiency being measured here refers to the circular cell, i.e. to a cell with a back electrode vapor-deposited across the whole surface. The efficiency of the square transparent cells, therefore, will be much lower still, which is why the idea of several PEDOT layers applied consecutively has to be discarded. Further experiments will attempt to minimize the cross-resistance of one PEDOT layer only.

It is noticeable that the resistance with two applied PEDOT layers is smaller than in the first experimental series, in which the PEDOT was applied directly onto the np TiO₂ layer. Presumably, the reason for this discrepancy is that in the first experiments the layers were applied immediately after each other, even though the first PEDOT layer had not yet dried out completely. In this experiment, the cell was placed on the hotplate at 60 °C between applying the two layers.

As expected, in this experimental series – in which the PEDOT was applied onto the p-type conductor – the cross-resistance with only one applied PEDOT layer was higher than when the PEDOT was applied onto the rough surface of the np TiO₂.

Increasing the PEDOT concentration of the solution:

As mentioned above, usually, the PEDOT solution is mixed with ethanol and isopropanol at a volume ratio of 1 : 1 : 1 in order to decrease the viscosity of the solution and obtain homogeneous layers through spin coating. When the PEDOT proportion in the mixture is increased, the solution's viscosity rises. Due to the higher viscosity, an increase in the thickness of the PEDOT layer remaining on the cell after spin coating is expected (for comparison: η_d , ethanol, 20°C = 1.19 mPas; η_d , isopropanol, 20°C = 2.43 mPas; η_d , PEDOT = 5-50 mPas).

In order to investigate the practical effect of the PEDOT solution's viscosity and the amount of substance it contains on layer thickness and therefore on the cross-resistance, the PEDOT proportion was increased a little to begin with, and then significantly. The volumetric mixture ratios ethanol : isopropanol : PEDOT tested here were as follows:

1 : 1 : 1
1 : 1 : 2
1 : 1 : 5
1 : 1 : 10
2 : 2 : 1

Since a preliminary experiment showed that small variations in PEDOT concentration do not result in significant differences as far as the resistance is concerned, the PEDOT proportion in the mixed solutions was increased considerably. This was the first experimental series in which the construction of the cells and the arrangement of the electrodes corresponded to those of the actual square cells.

The thickness of the cells' np TiO₂ layer was 1.3 micrometers. Each time, a PEDOT layer with a different proportion of PH 1000 was applied. The PEDOT solution was spun for 90 seconds at 2000 or 1500 1/min. Then the PEDOT layer was dried for ca. 1 minute with the hot air blower, before the silver electrodes (ca. 2 micrometers thick) were vapor-deposited.

Mixture	Number	RPM	R
---------	--------	-----	---

ratio	of layers	[1/min]	[k Ω]
1 : 1 : 1	1	2000	22 - 39
1 : 1 : 5			31 - 51
1 : 1 : 10			29 - 36
1 : 1 : 1	1	1500	21 - 27
1 : 1 : 5			21 - 32
1 : 1 : 10			26 - 37

Table 3: Cross-resistances for various mixture ratios and spin speeds of PEDOT layers.

As can be seen in Table 3, the cross-resistance does not decrease as expected with the increasing PEDOT proportion in the applied solution. Both at an angular velocity of 2000 and of 1500 1/min, the cross-resistance increases with the increasing PEDOT concentration in the solution. However, it is also noticeable that the resistance tends to decrease with decreasing RPM for the same PEDOT proportion, but is still 10-15 orders of magnitude too high.

Adjusting the time interval between application and spin coating of the PEDOT (Δt) and minimizing the RPM during spin coating:

The classic method for increasing layer thickness during spin coating is to decrease the angular velocity. In this way, layer thickness can easily be increased and the cross-resistance decreased. In the experimental series thus far, this was the only variation that led to a sensible result. The angular velocity during spin coating cannot, however, be decreased to an arbitrary value, since at excessively low RPM the solvent no longer evaporates sufficiently quickly which results in inhomogeneous PEDOT layers.

Tests have shown, however, that the time interval between applying the PEDOT solution to the substrate and starting the spin coating (and thus, removing excess solution from the substrate) has a significant effect on the cross-resistance. Therefore, subsequently, the cross-resistance was minimized through iterative optimization of the two parameters Δt and angular velocity during spin coating.

Therefore, over several tests series, the time interval Δt between applying the PEDOT solution to the cell and the start of spin coating was increased in steps from 30 seconds to 2 minutes, later in combination with RPM optimization from 1 to 3 minutes and finally from 3.5 to 5 minutes. This involves decreasing the RPM from 2000 1/min to 350 1/min. When decreasing the RPM to under 1000 1/min, 30 seconds turned out to no longer suffice for complete evaporation of the solvent. This time was, therefore, extended to 2 minutes in every case. Thereafter, the cells were dried with the hot air blower for approximately 1 minute before the electrodes were vapor-deposited.

RPM [1/min] 2000 1000 750 600 500 450 400 350

The results of the optimization are summarized in Tables 4 to 7.

- 5 In the first experimental series of the final optimization (Table 4), in which to begin with the time interval Δt between applying the PEDOT solution on the cell and spinning at constant angular velocity was increased, at an RPM of 1000 1/min there seems to be an optimum at $\Delta t = 60$ s (4.1 - 4.2 k Ω). For this time interval and a further decrease in RPM, a new minimum was obtained for 600 1/min (2.6 - 2.7 k Ω).

Mixture ratio	Number of layers	RPM [1/min]	Δt [s]	R [k Ω]
1 : 1 : 1	1	1000	30	8.5 - 8.7
			60	4.1 - 4.2
			90	4.7 - 4.8
			120	5.4 - 5.8
		750	60	9.0 - 9.2
		600	60	2.6 - 2.7
		500	60	3.7 - 4.0

Table 4: Optimization of the cross-resistance by optimizing the time interval Δt and the angular velocity during PEDOT solution spin coating – experimental series 1.

5

Mixture ratio	Number of layers	RPM [1/min]	Δt [s]	R [k Ω]
1 : 1 : 1	1	600	60	15.8 - 17.6
			90	11.0 - 11.6
			120	11.2 - 11.4
		500	60	6.0 - 6.8
			90	5.0
			120	6.4 - 6.8
			180	3.1 - 4.1

Table 5: Optimization of the cross-resistance by optimizing the time interval Δt and the angular velocity during PEDOT solution spin coating – experimental series 2.

10

Mixture ratio	Number of layers	RPM [1/min]	Δt [s]	R [k Ω]
1 : 1 : 1	1	500	180	0.4
		450	180	0.6
		400	180	1.1 - 1.3
		350	180	2.0 - 2.7
		350	210	1.8 - 2.5
		350	240	1.6
		350	270	1.5 - 1.8
		350	300	1.8 - 1.9

Table 6: Optimization of the cross-resistance by optimizing the time interval Δt and the angular velocity during PEDOT solution spin coating – experimental series 3.

5

Mixture ratio	Number of layers	RPM [1/min]	Δt [s]	R [k Ω]
1 : 1 : 1	1	500	180	1.3 - 2.4
		450	180	1.0 - 2.0

Table 7: Optimization of the cross-resistance by optimizing the time interval Δt and the angular velocity during PEDOT solution spin coating – experimental series 4.

10

Since, however, the results do not differ substantially between 600 and 500 1/min, in the next experimental series the time interval Δt was increased further stepwise for both RPM values. The results are shown in Table 5.

15 A further decrease in RPM and increase in Δt did not exhibit further improvement. In fact, the cross-resistance even increased again at an RPM < 450 1/min (see Table 6).

Since the values for 500 and 450 1/min lie very close together, a last comparative test was performed (see Table 7).

20

It was shown that the cross-resistance at an RPM of 450 1/min is slightly smaller than at 500 1/min. Since, however, no significant is achieved thereby and since PEDOT layers coated at an excessively low RPM are no longer homogeneous, 500 1/min was chosen as the optimal RPM. The time interval Δt is then 180 s.

25

Generally speaking, it is noticeable that the resistance values in the last set of experimental series, where there was a time interval between applying the PEDOT solution to the cell and starting the spinning, do not fluctuate as much within one series for constant parameters as

before. In the last experimental series (Table 7), the two cross-resistances were measured on each of four cells (left-right and top-bottom) and the results varied only by ca. 1 k Ω . The fact that in some cases the results from different series vary significantly for the same experimental parameters, is likely to be due to the production of the PEDOT solution since the individual experimental series in themselves provide coherent results.

The spin coater's open lid during the time interval Δt may be an important interference factor in these experiments. In one experimental series, it was not closed immediately after applying the PEDOT solution to the cell but only before spin coating. The cross-resistances measured in this experimental series are very much higher and there is a considerable variation in their values between the substrates – but not on any one substrate. It could not be determined exactly why the cross-resistance is so strongly influenced by the time interval Δt before the PEDOT solution's spin coating. Perhaps some of the PEDOT solution dries and adheres to the cell during this time, resulting in a thicker PEDOT layer.

Results of the optimized parameters:

The minimum cross-resistance obtained in this way lies between 1 and 3 k Ω . The parameters that bring about a minimum cross-resistance here were:

- PEDOT: Clevios[®] PH 1000 from Heraeus
- Number of layers: 1
- PEDOT : ethanol : isopropanol ratio = 1 : 1 : 1
- Time interval between applying and spin coating the PEDOT: $\Delta t = 180$ s
- RPM during PEDOT spin coating: $n = 500$ 1/min ($t = 120$ s)

The final cells used in the experiments:

The cells used during the optimization process so far were made on thick 2.5 mm TEC 8 glass carriers, with the FTO layer already applied during the fabrication process. They have a highly homogeneous FTO layer, onto which the application of homogeneous np TiO₂ layers is possible. This makes possible the fabrication of cells that appear homogeneous to the human eye.

For the technical realization of the sensor stack, however, the cells were made on thin 1 mm special glass carriers made of quartz glass, which were coated subsequently with FTO. Therein, loss carriers with beveled edges were used. The beveled edges served as bases for cells contacts. The silver contacts were vapor-deposited up to the edge of the bevels. This made it possible to contact the cells directly adjacent to each other in the stack individually with pins.

The subsequently applied FTO layer on these special carriers exhibited in part inhomogeneities arising from the fabrication process. The fabrication of homogeneous cells on these carriers

turned out to be very difficult, as was shown by generating current diagrams of the final cells. Even in the first cell of the stack which supplied a homogeneous current signal across its entire area, four locations were identified that supplied lower currents due to inhomogeneities. Current diagrams were obtained by exciting the cells with a laser at a wavelength 690 nm. The laser scanned the cells at 1 mm intervals. The cells were scanned in their final arrangement as a stack, i.e. the current diagram of the last cells was recorded with five 'thin' cells located in front of the last cell.

At the excitation wavelength of 690 nm, the developed cells had an extinction of 0.13. At the maximum (at ca. 550 nm) the extinction of these cells was ca. 0.4. Despite this low absorption by the cells and the fact that the back electrode consists of a poorly conducting – unlike silver – transparent layer, the efficiency of such a cell is still ~0.3% (AM 1.5*), that of the last cell ~2%.

Figures 2A, 4B and 4C show the final cells on the 1 mm special glass carriers. The first cell in the stack, which acts as the transversal optical sensor, requires the special electrode arrangement for x,y-resolution. For cells 2-5, which form the longitudinal optical sensor stack, only the total current is needed for z-resolution, which is why the contacting silver electrodes are combined here into one electrode surrounding the cell. Otherwise, however, the first five cells were made identically.

The last cell of the longitudinal optical sensor stack is intended to absorb the remaining light preferably completely, which is why it was chosen to have a significantly higher extinction than the front cells. In addition, it has a back electrode covering its entire area in order to supply maximum output current.

The cell shown in Fig. 2A, which forms the transversal optical sensor, in this experiment, was used only once for x,y resolution at position 1 in the stack. The cells in Fig. 4B were used four times in the entire stack of the optical sensors, i.e. for positions 2-5 of the entire stack. The last cell, which is depicted in Fig. 4C, was used at position 6 of the entire stack of optical sensors. Thus, generally, a stack of optical sensors was formed with the first optical sensor being the transversal optical sensor (Fig. 2A), followed by four transparent longitudinal optical sensors (Fig. 4B) and a last longitudinal optical sensor having the set-top of Fig. 4C.

When illuminating one of these single transparent final cells with a red laser (690 nm, 1 mW), this cell supplied a current of 30–40 microamps. The last longitudinal optical sensor provided a current of approximately 70 μ A. The cross-resistance between any two opposite electrodes in the first cell on these special glass carriers turned out to be 0.1 and 0.3 k Ω .

Since the fabrication of transparent cells on the special glass carriers was problematic due to the poor FTO coating, these cells had to be fabricated in large numbers. The cells were screened, and only selected cells were used for the final setup of the detector forming a prototype 3-D sensor. For this screening procedure, specifically for the transversal optical

sensor, the cells were excited by a laser beam (690 nm, 1 mW) at the center of the cell. If the cells are homogenous, the currents at all four contacts are equal ($I_1 = I_2 = I_3 = I_4$). By comparing the currents, specific cells were selected for use in the prototype.

- 5 The x,y resolution achieved with the detector of the set-top turned out to be approximately 1 mm at a distance of 3 m. The z-resolution of this detective setup turned out to be approximately 1 cm.

Patent claims

1. A detector (110) for determining a position of at least one object (112), comprising:
 - 5 - at least one transversal optical sensor (130), the transversal optical sensor (130) being adapted to determine a transversal position of at least one light beam (138) traveling from the object (112) to the detector (110), the transversal position being a position in at least one dimension perpendicular an optical axis (116) of the detector (110), the transversal optical sensor (130) being adapted to generate at least one transversal sensor signal;
 - 10 - at least one longitudinal optical sensor (132), wherein the longitudinal optical sensor (132) has at least one sensor region (136), wherein the longitudinal optical sensor (132) is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region (136) by the light beam (138), wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam (138) in the sensor region (136);
 - 15 - at least one evaluation device (142), wherein the evaluation device (142) is designed to generate at least one item of information on a transversal position of the object (112) by evaluating the transversal sensor signal and to generate at least one item of information on a longitudinal position of the object (112) by evaluating the longitudinal sensor signal.
 - 20
2. The detector (110) according to the preceding claim, wherein the transversal optical sensor (130) is a photo detector having at least one first electrode (160), at least one second electrode (170) and at least one photovoltaic material (164, 166, 168), wherein the photovoltaic material (164, 166, 168) is embedded in between the first electrode (160) and the second electrode (170), wherein the photovoltaic material (164, 166, 168) is adapted to generate electric charges in response to an illumination of the photovoltaic material (164, 166, 168) with light, wherein the second electrode (170) is a split electrode having at least two partial electrodes (176), wherein the transversal optical sensor (130) has a sensor region (136), wherein the at least one transversal sensor signal indicates a position of the light beam (138) in the sensor region (136).
 - 25
 - 30
3. The detector (110) according to the preceding claim, wherein electrical currents through the partial electrodes (176) are dependent on a position of the light beam (138) in the sensor region (136), wherein the transversal optical sensor (130) is adapted to generate the transversal sensor signal in accordance with the electrical currents through the partial electrodes (176).
 - 35
4. The detector (110) according to the preceding claim, wherein the detector (110) is adapted to derive the information on the transversal position of the object (112) from at least one ratio of the currents through the partial electrodes (176).
 - 40

5. The detector (110) according to any of the three preceding claims, wherein the photo detector is a dye-sensitized solar cell.
- 5 6. The detector (110) according to any of the four preceding claims, wherein the first electrode (160) at least partially is made of at least one transparent conductive oxide, wherein the second electrode (170) at least partially is made of an electrically conductive polymer (188), preferably a transparent electrically conductive polymer (188).
- 10 7. The detector (110) according to any of the preceding claims, wherein at least one of the transversal optical sensor (130) and the longitudinal optical sensor (132) is a transparent optical sensor.
- 15 8. The detector (110) according to any of the preceding claims, wherein the transversal optical sensor (130) and the longitudinal optical sensor (132) are stacked along the optical axis (116) such that a light beam (138) travelling along the optical axis (116) both impinges on the transversal optical sensor (130) and on the longitudinal optical sensor (132).
- 20 9. The detector (110) according to any of the preceding claims, wherein the longitudinal optical sensor (132) comprises at least one dye-sensitized solar cell.
- 25 10. The detector (110) according to the preceding claim, wherein the longitudinal optical sensor (132) comprises at least one first electrode (160), at least one n-semiconducting metal oxide (164), at least one dye (166), at least one p-semiconducting organic material (168), preferably a solid p-semiconducting organic material (168), and at least one second electrode (170).
- 30 11. The detector (110) according to the preceding claim, wherein both the first electrode (160) and the second electrode (170) are transparent.
- 35 12. The detector (110) according to any of the preceding claims, wherein the evaluation device (142) is designed to generate the at least one item of information on the longitudinal position of the object (112) from at least one predefined relationship between the geometry of the illumination and a relative positioning of the object (112) with respect to the detector (110).
13. The detector (110) according to any of the preceding claims, furthermore comprising at least one illumination source (192).
- 40 14. The detector (110) according to any of the preceding claims, wherein the detector (110) has a plurality of longitudinal optical sensors (132), wherein the longitudinal optical sensors (132) are stacked.

15. The detector (110) according to the preceding claim, wherein the longitudinal optical sensors (132) are arranged such that a light beam (138) from the object (112) illuminates all longitudinal optical sensors (132), wherein at least one longitudinal sensor signal is generated by each longitudinal optical sensor (132), wherein the evaluation device (142) is adapted to normalize the longitudinal sensor signals and to generate the information on the longitudinal position of the object (112) independent from an intensity of the light beam (138).
16. The detector (110) according to any of the two preceding claims, wherein a last longitudinal optical sensor (144) is arranged in a manner that the light beam (138) illuminates all other longitudinal optical sensors (132) apart from the last longitudinal optical sensor (144), until the light beam (138) impinges on the last longitudinal optical sensor (144), wherein the last longitudinal optical sensor (144) is intransparent with respect to the light beam (138).
17. The detector (110) according to any of the three preceding claims, wherein the stack of at least two optical sensors is partially or fully be immersed in an oil, in a liquid and/or in a solid material.
18. The detector (110) according to any of the preceding claims, wherein the at least one transversal optical sensor and/or the at least one longitudinal optical sensor uses at least two different transparent substrates.
19. The detector (110) according to any of the preceding claims, wherein the detector (110) further comprises at least one imaging device (157).
20. The detector (110) according to any of the preceding claims, wherein the detector (110) further comprises at least one optically sensitive element (159).
21. The detector (110) according to any of the preceding claims, wherein the optically sensitive element (161) comprises a color wheel (163), a color drum, and/or a filter wheel using an elliptically polarizing filter.
22. The detector (110) according to any of the preceding claims, wherein the evaluation device (142) is adapted to generate the at least one item of information on the longitudinal position of the object (112) by determining a diameter of the light beam (138) from the at least one longitudinal sensor signal.
23. The detector (110) according to the preceding claim, wherein the evaluation device (142) is adapted to compare the diameter of the light beam (138) with known beam properties of

the light beam (138) in order to determine the at least one item of information on the longitudinal position of the object (112).

24. The detector (110) according to any of the preceding claims, wherein the longitudinal optical sensor (132) is furthermore designed in such a way that the longitudinal sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination.
25. A human-machine interface (196) for exchanging at least one item of information between a user (200) and a machine, wherein the human-machine interface (196) comprises at least one detector (110) according to any of the preceding claims relating to a detector (110), wherein the human-machine interface (196) is designed to generate at least one item of geometrical information of the user (200) by means of the detector (110) wherein the human-machine interface (196) is designed to assign to the geometrical information at least one item of information.
26. An entertainment device (198) for carrying out at least one entertainment function, wherein the entertainment device (198) comprises at least one human-machine interface (196) according to any of the preceding claims referring to a human-machine interface (196), wherein the entertainment device (198) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (196), wherein the entertainment device (198) is designed to vary the entertainment function in accordance with the information.
27. A tracking system (199) for tracking the position of at least one movable object (112), the tracking system (199) comprising at least one detector (110) according to any of the preceding claims referring to a detector (110), the tracking system (199) further comprising at least one track controller (201), wherein the track controller (201) is adapted to track a series of positions of the object (112), each position comprising at least one item of information on a transversal position of the object (112) at a specific point in time and at least one item of information on a longitudinal position of the object (112) at a specific point in time.
28. A camera (111) for imaging at least one object (112), the camera (111) comprising at least one detector (110) according to any one of the preceding claims referring to a detector (110).
29. A method for determining a position of at least one object (112),
- wherein at least one transversal optical sensor (130) of a detector (110) is used, wherein the transversal optical sensor (130) determines a transversal position of at least one light beam (138) traveling from the object (112) to the detector (110), the transversal position being a position in at least one dimension perpendicular to an optical axis (116) of the

- detector (110), wherein the transversal optical sensor (130) generates at least one transversal sensor signal;
- wherein at least one longitudinal optical sensor (132) of the detector (110) is used, wherein the longitudinal optical sensor (132) has at least one sensor region (136), wherein the longitudinal optical sensor (132) generates at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region (136) by the light beam (138), wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam (138) in the sensor region (136);
 - wherein at least one evaluation device (142) is used, wherein the evaluation device (142) generates at least one item of information on a transversal position of the object (112) by evaluating the transversal sensor signal and wherein the evaluation device (142) further generates at least one item of information on a longitudinal position of the object (112) by evaluating the longitudinal sensor signal.
30. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use, selected from the group consisting of: a distance measurement, in particular in traffic technology; a position measurement, in particular in traffic technology; a tracking application, in particular in traffic technology.
31. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use as an entertainment application.
32. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use as a camera (111), in particular in a security application.
33. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use as a human-machine interface (196) application.
34. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use as a mapping application, in particular for generating maps of at least one space.
35. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use in automated machine processes, selected from the group consisting of: a distance measurement; a position measurement; a tracking application.
36. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use in high-precision metrology, in particular in analytics.

37. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use in modeling of manufacturing parts.
 38. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use in medical operations, in particular in endoscopic methods.

This collection of information is required by 37 CFR 1.97 and 1.98. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 1 hour to complete, including gathering, preparing and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether the Freedom of Information Act requires disclosure of these records.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspections or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

(54)发明名称

一种基于双目结构光的三维手势控制智能电视的方法

(57)摘要

本发明公开了一种基于双目结构光的三维手势控制智能电视的方法,包括以下步骤:首先通过双目摄像头同步采集图像,根据获得的左右视图重建出具有深度信息的三维图像,并进行预处理,分割出三维手势后,再对手势动作进行识别,将识别出的手势动作转换为智能电视的操作指令,并执行。本发明采用双目视觉和结构光结合的方式,可以有效地提高环境抗干扰能力、降低光照条件的便会对指尖定位的影响;满足控制智能电视的实时性和有效性。

1. 一种基于双目结构光的三维手势控制智能电视的方法,其特征在于,包括如下步骤:

步骤一,采集图像:通过设置于智能电视内的双目摄像头捕获摄像头前方图像,采集到的左视图、右视图分别储存进储存器,再由处理器分别处理储存器内的两张图片;

步骤二,重建图像三维:根据双目匹配算法,找出左视图、右视图之间各像素点的一一对应关系,根据他们之间的像素位置的横坐标差得到视差图,然后根据投影模型与三角测量原理,获得原始图像的深度信息;

步骤三,预处理深度图像:对深度图像进行中值滤波去除噪声点,再对深度图像中的内部空洞进行形态学处理;

步骤四,检测手势图像:对获得的图像深度数据进行分析,将人和背景分离开来,只选取人体的像素信息,将其余像素信息全部置零,获得人体的深度图像,最后获得手势的轮廓;

步骤五,识别三维手势:根据获得的手势轮廓,对手势轮廓提取中心距特征,中心距是指图形中必点到各边缘点的距离;设点 $O(x_0, y_0)$ 为手势的几何中心点,点集 $C = \{(x_i, y_i) | i = 1, 2, \dots, N\}$ 为手势的边缘轮廓,不妨把手势的边缘轮廓看成有一个个边缘点连接而成,由此,几何中心点 $O(x_0, y_0)$ 和中心距 d 可由如下公式计算:

$$x_0 = \frac{1}{N} \sum_{i=1}^N x_i;$$

$$y_0 = \frac{1}{N} \sum_{i=1}^N y_i;$$

$$d_i = \sqrt{(x_i - x_0)^2 + (y_i - y_0)^2};$$

再结合三维信息,利用基于贝叶斯网络的分类器进行识别;

步骤六,执行操作指令:根据在双目摄像头前做出的手势,智能电视执行相应的预先设定的操作指令,完成人机交互。

2. 根据权利要求1所述的一种基于双目结构光的三维手势控制智能电视的方法,其特征在于,步骤一,采集图像:通过红外探测器探测操作环境的光照情况,若红外光过多则打开红外激光器;再通过设置于智能电视内的双目摄像头捕获摄像头前方图像,采集到的左视图、右视图分别储存进储存器,再由处理器分别处理储存器内的两张图片。

3. 根据权利要求2所述的一种基于双目结构光的三维手势控制智能电视的方法,其特征在于,若红外探测器探测操作环境的红外辐射强度小于 $0.2\text{W}/\text{m}^2 \cdot 850\text{nm}$,则打开红外激光器。

4. 根据权利要求1所述的一种基于双目结构光的三维手势控制智能电视的方法,其特征在于,上述步骤三中的形态学处理即对图像边缘存在的毛刺和图像的内部空洞进行开、闭运算。

5. 根据权利要求1所述的一种基于双目结构光的三维手势控制智能电视的方法,其特征在于,上述步骤四中获得手势的轮廓的具体步骤为:通过像素的灰度值反映改点距离镜头的远近,统计出人体的深度图像的灰度分布直方图,灰度直方图较小的峰是手部区域的灰度分布,较大的峰是人体躯干的灰度分布,从而分割出人体的手部图像,再对手部图像使用Canny边缘算了进行边缘检测,从而获得手势的轮廓。

6. 根据权利要求1所述的一种基于双目结构光的三维手势控制智能电视的方法, 其特征在于, 上述步骤五中利用基于贝叶斯网络的分类器进行识别的具体步骤如下:

步骤a, 计算不同手势类别下所有特征的高斯分布信息, 即是计算所有的均值与方差;

步骤b, 对于测试的每一个输入样本, 求出它在手势1类别下, 各个特征的概率, 由于每个特征是相互独立的, 因而特征下的概率分布也满足独立性, 由此便可以得出该输入样本在手势1类别下的总概率; 以此类推, 求出该样本在所有手势类别下的不同概率;

步骤c, 比较输入样本在不同类别下得到概率值, 找出其最大概率值所属的类别, 便预测该类别就是输入样本所属的类别。

一种基于双目结构光的三维手势控制智能电视的方法

技术领域

[0001] 本发明涉及人机交互领域,特别是一种手势控制的方法。

背景技术

[0002] 随着互联网技术的发展,智能电视——一种具备开放式操作系统与芯片,拥有开放式应用平台,可实现双向人机交互功能,集影音、娱乐、数据等多种功能于一体,以满足用户多样化和个性化需求的电视产品成为了电视的潮流趋势。

[0003] 传统的按键式遥控器主要是由集成电路电板和用来产生不同讯息的按钮所组成。内装有一个中央处理器CPU,CPU在制造时就将电视机各种菜单密码信息输入其中,电视机的遥控发射器只要发出与之对应的密码就可以实现电视机的遥控了。

[0004] 智能电视的发展对电视的交互操作提出了更多的要求。首先便是需要简洁方便的文字输入、网页浏览和频道选取,传统的遥控器显然无法满足新的交互需求。如果在智能电视上外接鼠标和键盘,用户则需要配置多个控制终端,且无法在远距离(3~5米)和复杂环境下(鼠标、键盘需要相对平坦的桌面)完成交互,给用户操作带来了很多的障碍。这也是目前电视的人机交互落后于计算机和手持设备的原因。

[0005] 日前,基于视觉的电视人机交互成为一个主流技术,而手势识别是其中非常重要的研究领域。手势语言是一种依靠动作和视觉进行交际的特殊语言,它是包含信息量最多的人体语言。而手势识别的本质就是根据用户的手势,识别出所表达的意义。然而目前的手势检测、指尖定位等图像处理技术大部分是基于二维的,适合近距离、简单背景的,不符合智能电视的交互需求。而三维手势识别能够判断出三维空间内的手势变化,以更为自然、直观的交互方式得到广泛关注,但是日前来讲,一些三维手势识别设备使用了数据手套,虽然其识别率高,但也失去了手势交互的自然性,费用也很昂贵;一些利用飞行时间的设备,对硬件要求高、费用高昂、分辨率也较低;基于双目视觉的设备视角较小、在昏暗环境下以及特征不明显的情况下效果较差;而基于结构光的设备非常容易受到光照影响。可以说现有的手势识别设备都存在不同程度的缺陷。

发明内容

[0006] 为解决现有技术的不足,本发明的目的在于提供一种基于双目结构光的三维手势控制智能电视的方法,本发明通过双目摄像头和红外结构光结合的方式获得优质的双手的三维信息,然后进行实时手势分割、检测以及指尖定位,完成三维手势动作与电视指令的实时转换,满足电视人机交互操作实时性的要求。

[0007] 为了实现上述目标,本发明采用如下的技术方案:

[0008] 一种基于双目结构光的三维手势控制智能电视的方法,包括如下步骤:

[0009] 步骤一,采集图像:通过设置于智能电视内的双目摄像头捕获摄像头前方图像,采集到的左视图、右视图分别储存进储存器,再由处理器分别处理储存器内的两张图片;

[0010] 步骤二,重建图像三维:根据双目匹配算法,找出左视图、右视图之间各像素点的

一一对应关系,根据他们之间的像素位置的横坐标差得到视差图,然后根据投影模型与三角测量原理,获得原始图像的深度信息;

[0011] 步骤三,预处理深度图像;对深度图像进行中值滤波去除噪声点,并对深度图像中的内部空洞进行形态学处理;

[0012] 步骤四,检测手势图像;对获得的图像深度数据进行分析,将人和背景分离开来,只选取人体的像素信息,将其余像素信息全部置零,获得人体的深度图像,最后获得手势的轮廓;

[0013] 步骤五,识别三维手势;根据获得的手势轮廓,对手势轮廓提取中心距特征,中心距是指图形中必点到各边缘点的距离;设点 $O(x_0, y_0)$ 为手势的几何中心点,点集 $C = \{(x_i, y_i) | i = 1, 2, \dots, N\}$ 为手势的边缘轮廓,不妨把手势的边缘轮廓看成有一个个边缘点连接而成,由此,几何中心点 $O(x_0, y_0)$ 和中心距 d 可由如下公式计算:

$$[0014] \quad x_0 = \frac{1}{N} \sum_{i=1}^N x_i;$$

$$[0015] \quad y_0 = \frac{1}{N} \sum_{i=1}^N y_i;$$

$$[0016] \quad d_i = \sqrt{(x_i - x_0)^2 + (y_i - y_0)^2};$$

[0017] 再结合三维信息,利用基于贝叶斯网络的分类器进行识别;

[0018] 步骤六,执行操作指令;根据在双目摄像头前做出的手势,智能电视执行相应的预先设定的操作指令,完成人机交互。

[0019] 前述的一种基于双目结构光的三维手势控制智能电视的方法,步骤一,采集图像;通过红外探测器探测操作环境的光照情况,若红外光过多则打开红外激光器;再通过设置于智能电视内的双目摄像头捕获摄像头前方图像,采集到的左视图、右视图分别储存进储存器,再由处理器分别处理储存器内的两张图片。

[0020] 前述的一种基于双目结构光的三维手势控制智能电视的方法,若红外探测器探测操作环境的红外辐射强度小于 $0.2W/m^2 \times 850nm$,则打开红外激光器。

[0021] 前述的一种基于双目结构光的三维手势控制智能电视的方法,步骤三中的形态学处理即对图像边缘存在的毛刺和图像的内部空洞进行开、闭运算。

[0022] 前述的一种基于双目结构光的三维手势控制智能电视的方法,步骤四中获得手势的轮廓的具体步骤为:通过像素的灰度值反映改点距离镜头的远近,统计出人体的深度图像的灰度分布直方图,灰度直方图较小的峰是手部区域的灰度分布,较大的峰是人体躯干的灰度分布,从而分割出人体的手部图像,再对手部图像使用Canny边缘算子进行边缘检测,从而获得手势的轮廓。

[0023] 前述的一种基于双目结构光的三维手势控制智能电视的方法,步骤五中利用基于贝叶斯网络的分类器进行识别的具体步骤如下:

[0024] 步骤a,计算不同手势类别下所有特征的高斯分布信息,即是计算所有的均值与方差;

[0025] 步骤b,对于测试的每一个输入样本,求出它在手势 l 类别下,各个特征的概率,由于每个特征是相互独立的,因而特征下的概率分布也满足独立性,由此便可以得出该输入

样本在手势1类别下的总概率;以此类推,求出该样本在所有手势类别下的不同概率;

[0026] 步骤c,比较输入样本在不同类别下得到概率值,找出其最大概率值所属的类别,便预测该类别就是输入样本所属的类别。

[0027] 本发明的有益之处在于:本发明提供一种基于双目结构光的三维手势控制智能电视的方法,本发明通过双目摄像头和红外结构光结合的方式获得优质的双手的三维信息,然后进行实时手势分割、检测以及指尖定位,完成三维手势动作与电视指令的实时转换,满足电视人机交互操作实时性的要求;

[0028] 本发明因为采用了双目视觉和结构光结合的方式,可以有效地提高环境抗干扰能力、降低光照条件的便会对指尖定位的影响,当在室内或环境昏暗时采用结构光测量深度信息,当太阳光照较强时则转为纯双目的方式。而且双目结构光的标定与激光器无关,当激光器损坏时替换较为方便;

[0029] 本发明通过对手势图像的前景分割减少了手势检测的遍历范围,可以满足电视人机交互操作实时性的要求。

附图说明

[0030] 图1是本发明的一种实施例的结构示意图;

[0031] 图中附图标记的含义:

[0032] 1红外摄像头,2红外探测器,3红外激光器,4电视。

具体实施方式

[0033] 以下结合附图和具体实施例对本发明作具体的介绍。

[0034] 如图1所示,本发明的所需的所有模块都集成在智能电视4当中。水平安装在智能电视4左右两边的是已经标定好的红外摄像头1,用于获取左右视角的图像。在两个红外摄像头1中间的是红外激光器3,用来发出红外条纹光,增加表面纹理,便于双目匹配,方便在昏暗条件下依旧能够准确识别手势。激光器旁边的是红外探测器2,用来监测操作环境的红外情况,以选择是否打开红外激光器3。而后续的图像三维重建、深度图像预处理、手势图像检测、三维手势识别以及人机交互则由智能电视4内的处理器来完成。

[0035] 一种基于双目结构光的三维手势控制智能电视4的方法,包括如下步骤:

[0036] 步骤一,采集图像;

[0037] 先通过红外探测器2探测操作环境的红外辐射情况,若红外辐射强度大于 $0.2\text{W}/\text{m}^2 \times 850\text{nm}$,激光器发出的编码光斑容易被淹没,则选用纯双目的方式;若红外辐射强度小于 $0.2\text{W}/\text{m}^2 \times 850\text{nm}$,编码光斑不容易被干扰,则打开红外激光器3,以提高双目匹配精度。

[0038] 再打开水平安装在智能电视4机内已经标定好的两个相同型号的红外摄像头1,双目摄像头以25帧每秒捕获摄像头前方图像,采集到的图像大小为 640×480 的RGB彩色空间的数字图像,并将双目摄像头拍摄的的左视图、右视图分别储存在智能电视4里两个独立的存储空间,再由处理器分别处理储存器内的两张图片。

[0039] 步骤二,重建图像三维;根据双目匹配算法,找出左视图、右视图之间各像素点的一一对应关系,根据他们之间的像素位置的横坐标差得到视差图,然后根据投影模型与三角测量原理,获得原始图像的深度信息;

[0040] 步骤三, 预处理深度图像; 由于获得的深度图像中手势边缘的深度值不稳定, 有许多0值噪声点, 直接处理会对算法的效果造成影响, 因此采用中值滤波去除噪声点, 降低目标边缘的模糊程度。再对深度图像中的内部空洞进行形态学处理; 形态学处理即对图像边缘存在的毛刺和图像的内部空洞进行开、闭运算。

[0041] 步骤四, 检测手势图像; 对获得的图像深度数据进行分析, 将人和背景分离开来, 只选取人体的像素信息, 将其余像素信息全部置零, 获得人体的深度图像, 最后获得手势的轮廓; 获得手势的轮廓的具体步骤为: 通过像素的灰度值反映改点距离镜头的远近, 统计出人体的深度图像的灰度分布直方图, 灰度直方图较小的峰是手部区域的灰度分布, 较大的峰是人体躯干的灰度分布, 从而分割出人体的手部图像, 再对手部图像使用Canny边缘算子进行边缘检测, 从而获得手势的轮廓。

[0042] 步骤五, 识别三维手势; 根据获得的手势轮廓, 对手势轮廓提取中心距特征(SCCD), 中心距是指图形中必点到各边缘点的距离; 设点 $O(x_0, y_0)$ 为手势的几何中心点, 点集 $C = \{(x_i, y_i) | i = 1, 2, \dots, N\}$ 为手势的边缘轮廓, 不妨把手势的边缘轮廓看成有一个个边缘点连接而成, 由此, 几何中心点 $O(x_0, y_0)$ 和中心距 d 可由如下公式计算:

$$[0043] \quad x_0 = \frac{1}{N} \sum_{i=1}^N x_i;$$

$$[0044] \quad y_0 = \frac{1}{N} \sum_{i=1}^N y_i;$$

$$[0045] \quad d_i = \sqrt{(x_i - x_0)^2 + (y_i - y_0)^2};$$

[0046] 再结合三维信息, 利用基于贝叶斯网络的分类器进行识别;

[0047] 利用基于贝叶斯网络的分类器进行识别的具体步骤如下:

[0048] 步骤a, 计算不同手势类别下所有特征的高斯分布信息, 即是计算所有的均值与方差;

[0049] 步骤b, 对于测试的每一个输入样本, 求出它在手势 l 类别下, 各个特征的概率, 由于每个特征是相互独立的, 因而特征下的概率分布也满足独立性, 由此便可以得出该输入样本在手势 l 类别下的总概率; 以此类推, 求出该样本在所有手势类别下的不同概率;

[0050] 步骤c, 比较输入样本在不同类别下得到概率值, 找出其最大概率值所属的类别, 便预测该类别就是输入样本所属的类别。

[0051] 步骤六, 执行操作指令; 根据在双目摄像头前做出的手势, 智能电视4执行相应的预先设定的操作指令, 完成人机交互。

[0052] 本发明提供一种基于双目结构光的三维手势控制智能电视4的方法, 本发明通过双目摄像头和红外结构光结合的方式获得优质的双手的三维信息, 然后进行实时手势分割、检测以及指尖定位, 完成三维手势动作与电视4指令的实时转换, 满足电视4人机交互操作实时性的要求;

[0053] 本发明因为采用了双目视觉和结构光结合的方式, 可以有效地提高环境抗干扰能力、降低光照条件的便会对指尖定位的影响, 当在室内或环境昏暗时采用结构光测量深度信息, 当太阳光照较强时则转为纯双日的方式。而且双目结构光的标定与激光器无关, 当激光器损坏时替换较为方便;

[0054] 本发明通过对手势图像的前景分割减少了手势检测的遍历范围,可以满足电视4人机交互操作实时性的要求。

[0055] 以上显示和描述了本发明的基本原理、主要特征和优点。本行业的技术人员应该了解,上述实施例不以任何形式限制本发明,凡采用等同替换或等效变换的方式所获得的技术方案,均落在本发明的保护范围内。

DESCRIPTION CN108363482A

¹⁰ Method for controlling smart TV with three-dimensional gesture based on binocular structured light

[0001]

¹⁴ Technical field

[0002]

¹⁸ The invention relates to the field of human-computer interaction, in particular to a method of gesture control.

[0003]

²² Background technique

[0004]

²⁶ With the development of Internet technology, smart TV-an open operating system and chip, with an open application platform, can achieve two-way human-computer interaction, and integrate multiple functions such as audio and video, entertainment, and data to meet TV products with diversified and individual needs of users have become the trend of TV.

[0005]

³³ The traditional push-button remote control is mainly composed of an integrated circuit board and buttons used to generate different messages.

³⁵ It is equipped with a central processing unit CPU, and the CPU inputs various menu password information of the TV when it is manufactured, and the remote control transmitter of the TV can realize the remote control of the TV as long as the corresponding password is issued.

[0006]

⁴¹ The development of smart TV puts forward more requirements on the interactive operation of the TV.

⁴² The first is the need for simple and convenient text input, web browsing and channel selection. The traditional remote control obviously cannot meet the new interactive needs.

⁴⁴ If an external mouse and keyboard are connected to the smart TV, the user needs to configure multiple control terminals, and it is not possible to complete the interaction in a long distance (3 to 5 meters) and in a complex environment (mouse and keyboard require a relatively flat desktop) to operate for the user Brings a lot of obstacles.

⁴⁸ This is also the reason why the current human-computer interaction of TV lags behind computers and handheld devices.

[0007]

⁵³ At present, vision-based television human-computer interaction has become a mainstream technology, and gesture recognition is a very important research field.

⁵⁵ Gesture language is a special language that relies on movement and vision to communicate. It is the human body language that contains the most information.

⁵⁷ The essence of gesture recognition is to recognize the meaning expressed according to the user's gestures.

However, most of the current image processing technologies such as gesture detection and fingertip positioning are based on two-dimensional, suitable for short-distance, simple background, and do not meet the interactive requirements of smart TVs. The three-dimensional gesture recognition can determine the gesture changes in the three-dimensional space, and has attracted widespread attention in a more natural and intuitive way of interaction. However, at present, some three-dimensional gesture recognition devices use data gloves. Although its recognition rate is high, it is also The naturalness of gesture interaction is lost, and the cost is also very expensive; some devices that use time of flight have high hardware requirements, high costs, and low resolution; devices based on binocular vision have small viewing angles, in dim environments, and features The effect is poor when it is not obvious; and equipment based on structured light is very susceptible to light. It can be said that the existing gesture recognition devices have various degrees of defects.

[0008]

⁷¹ Summary of the invention

[0009]

⁷⁵ In order to solve the shortcomings of the prior art, the purpose of the present invention is to provide a method for controlling a smart TV with a three-dimensional gesture based on binocular structured light. The present invention obtains high-quality three-dimensional information of both hands through a combination of binocular camera and infrared structured light. , And then perform real-time gesture segmentation, detection, and fingertip positioning to complete the real-time conversion of three-dimensional gesture actions and TV

commands to meet the real-time requirements of TV human-computer interactive operations.

[0010]

⁸⁴ In order to achieve the above objectives, the present invention adopts the following technical solutions:

[0011]

⁸⁸ A method for controlling a smart TV with a three-dimensional gesture based on binocular structured light includes the following steps:

[0012]

⁹³ Step one, capture images; capture images in front of the camera through the binocular camera set in the smart TV, and store the collected left view and right view into the memory respectively, and then the processor processes the two images in the memory respectively;

[0013]

⁹⁹ Step two, reconstruct the image in three dimensions; according to the binocular matching algorithm, find the one-to-one correspondence between the pixels of the left view and the right view, and obtain the disparity map according to the abscissa difference of the pixel positions between them, and then according to the projection model With the principle of triangulation, the depth information of the original image is obtained;

[0014]

¹⁰⁶ Step three, preprocess the depth image; perform median filtering on the depth image to remove noise points, and then perform morphological processing on the internal holes in the depth image;

[0015]

¹¹¹ Step 4: Detect the gesture image; analyze the obtained image depth data, separate the person from the background, select only the pixel information of the human body, and set all other pixel information to zero to obtain the depth image of the human body, and finally obtain the contour of the gesture ;

[0016]

¹¹⁷ Step 5: Recognize the three-dimensional gesture; extract the center distance feature of the gesture contour according to the obtained gesture contour. The center distance refers to the distance between the necessary point in the graph and each edge point; set the point $O(x_0, y_0)$ as the geometric center point of the gesture , The point set $C=\{(x_i, y_i)|i=1, 2, \dots, N\}$ is the edge contour of the gesture. It may be considered that the edge contour of the gesture is formed by connecting edge points. Therefore, the geometric center The point $O(x_0,$

y0) and the center distance d can be calculated by the following formula:

[0020]

¹²⁶ Combined with three-dimensional information, use the classifier based on Bayesian network for recognition;

[0021]

¹³⁰ Step 6, execute the operation instruction; according to the gesture made in front of the binocular camera, the smart TV executes the corresponding preset operation instruction to complete the human-computer interaction.

[0022]

¹³⁶ The aforementioned method for controlling a smart TV with three-dimensional gestures based on binocular structured light. Step one is to collect images; detect the lighting conditions of the operating environment through an infrared detector; if there is too much infrared light, turn on the infrared laser; The binocular camera in the TV captures the image in front of the camera, and the collected left view and right view are respectively stored in the memory, and then the two pictures in the memory are processed by the processor.

[0023]

¹⁴⁴ In the aforementioned method for controlling a smart TV with a three-dimensional gesture based on binocular structured light, if the infrared detector detects that the infrared radiation intensity of the operating environment is less than $0.2\text{W}/\text{m}^2 \cdot 850\text{nm}$, the infrared laser is turned on.

[0024]

¹⁵⁰ In the aforementioned method for controlling a smart TV with a three-dimensional gesture based on binocular structured light, the morphological processing in step 3 is to open and close the burr existing on the edge of the image and the internal cavity of the image.

[0025]

¹⁵⁶ In the aforementioned method for controlling a smart TV with a three-dimensional gesture based on binocular structured light, the specific steps for obtaining the outline of the gesture in step 4 are: the gray value of the pixel reflects the distance of the changed point from the lens, and the depth image of the human body is calculated. The grayscale distribution histogram of the grayscale histogram, the smaller peak of the grayscale histogram is the gray distribution of the hand area, and the larger peak is the gray distribution of the human torso, so as to segment the human hand image, and then use the hand image. The Canny edge operator performs edge detection to obtain the contour of the gesture.

[0026]

¹⁶⁶ In the foregoing method for controlling a smart TV with a three-dimensional gesture based on binocular structured light, the specific steps of using a Bayesian network-based classifier for recognition in step 5 are as follows:

[0027]

¹⁷² Step a: Calculate the Gaussian distribution information of all features in different gesture categories, that is, calculate all the mean and variance;

[0028]

¹⁷⁷ Step b: For each input sample tested, find the probability of each feature in the gesture 1 category. Since each feature is independent of each other, the probability distribution under the feature also satisfies the independence, which can be obtained Find the total probability of the input sample in the gesture 1 category; and so on, find the different probabilities of the sample in all gesture categories;

[0029]

¹⁸⁴ Step c: Compare the probability values of the input samples under different categories, find the category to which the maximum probability value belongs, and predict that the category is the category to which the input sample belongs.

[0030]

¹⁹⁰ The advantage of the present invention is that the present invention provides a method for controlling a smart TV with a three-dimensional gesture based on binocular structured light. The present invention obtains high-quality three-dimensional information of both hands through a combination of binocular camera and infrared structured light, and then performs Real-time gesture segmentation, detection, and fingertip positioning, complete the real-time conversion of three-dimensional gesture actions and TV commands, and meet the real-time requirements of TV man-machine interactive operations;

[0031]

¹⁹⁹ Because the invention adopts the combination of binocular vision and structured light, it can effectively improve the environment's anti-interference ability and reduce the influence of light conditions on fingertip positioning. When indoors or when the environment is dim, the structured light is used to measure depth information , When the sun is strong, it turns to a pure binocular way.

²⁰³ Moreover, the calibration of binocular structured light has nothing to do with the laser, and it is more convenient to replace when the laser is damaged;

[0032]

²⁰⁸ The invention reduces the traversal range of the gesture detection by segmenting the foreground of the gesture image, and can meet the real-time requirements of the television human-computer interactive operation.

[0033]

²¹³ Description of the drawings

[0034]

²¹⁷ Figure 1 is a schematic structural diagram of an embodiment of the present invention;

[0035]

²²¹ The meaning of the reference signs in the figure:

[0036]

²²⁵ 1 Infrared camera, 2 infrared detectors, 3 infrared lasers, 4 TVs.

[0037]

²²⁹ Detailed ways

[0038]

²³³ Hereinafter, the present invention will be described in detail with reference to the drawings and specific embodiments.

[0039]

²³⁸ As shown in FIG. 1, all the modules required by the present invention are integrated in the smart TV 4.

²³⁹ Horizontally installed on the left and right sides of the smart TV 4 are calibrated infrared cameras 1 for obtaining images with left and right viewing angles.

²⁴¹ In the middle of the two infrared cameras 1 is an infrared laser 3, which is used to emit infrared fringe light, increase the surface texture, facilitate binocular matching, and facilitate accurate recognition of gestures in dim conditions.

²⁴⁴ Next to the laser is an infrared detector 2, which is used to monitor the infrared situation of the operating environment to choose whether to turn on the infrared laser 3.

²⁴⁶ The subsequent image 3D reconstruction, depth image preprocessing, gesture image detection, 3D gesture recognition, and human-computer interaction are completed by the processor in the smart TV 4.

[0040]

251 A method for controlling a smart TV 4 with a three-dimensional gesture based on binocular structured light includes the following steps:

[0041]

256 Step one, collect images;

[0042]

260 First detect the infrared radiation of the operating environment through the infrared detector 2. If the infrared radiation intensity is greater than $0.2W/m^2 \cdot 850nm$, the coded spot emitted by the laser is likely to be submerged, and the pure binocular method is used; if the infrared radiation intensity is less than $0.2W/m^2 \cdot 850nm$, the coded spot is not easy to be disturbed, then turn on the infrared laser 3 to improve the accuracy of binocular matching.

[0043]

268 Then turn on the two infrared cameras 1 of the same model that have been calibrated horizontally installed in the smart TV 4. The binocular camera captures the front image of the camera at 25 frames per second, and the collected image size is 640×480 in the RGB color space. Digital images, and the left view and right view taken by the binocular camera are respectively stored in two independent storage spaces in the smart TV 4, and then the two pictures in the storage are processed by the processor.

[0044]

276 Step two, reconstruct the image in three dimensions; according to the binocular matching algorithm, find the one-to-one correspondence between the pixels of the left view and the right view, and obtain the disparity map according to the abscissa difference of the pixel positions between them, and then according to the projection model With the principle of triangulation, the depth information of the original image is obtained;

[0045]

283 Step three, preprocess the depth image; because the depth value of the gesture edge in the obtained depth image is unstable, there are many zero-value noise points, direct processing will affect the effect of the algorithm, so the median filter is used to remove the noise points and reduce the target The degree of blurring of the edges.

287 Morphological processing is performed on the internal cavity in the depth image; the morphological processing is to open and close the burr existing on the edge of the image and the internal cavity of the image.

[0046]

²⁹² Step 4: Detect the gesture image; analyze the obtained image depth data, separate the person from the background, select only the pixel information of the human body, and set all other pixel information to zero to obtain the depth image of the human body, and finally obtain the contour of the gesture ; The specific steps to obtain the contour of the gesture are; the gray value of the pixel reflects the distance of the changed point from the lens, and the gray distribution histogram of the depth image of the human body is calculated. The smaller peak of the gray histogram is the hand area Gray-scale distribution, the larger peak is the gray-scale distribution of the human torso, thereby segmenting the human hand image, and then using the Canny edge operator to perform edge detection on the hand image to obtain the contour of the gesture.

[0047]

³⁰³ Step 5: Recognize the three-dimensional gesture; extract the center distance feature (SCCD) of the gesture contour according to the obtained gesture contour. The center distance refers to the distance from the edge point to the edge point in the figure; set point $O(x_0, y_0)$ as the gesture The geometric center point, point set $C = \{(x_i, y_i) | i = 1, 2, \dots, N\}$ is the edge contour of the gesture. It may be considered that the edge contour of the gesture is formed by connecting edge points. , The geometric center point $O(x_0, y_0)$ and the center distance d can be calculated by the following formula:

[0051]

³¹² Combined with three-dimensional information, use the classifier based on Bayesian network for recognition;

[0052]

³¹⁶ The specific steps of using a Bayesian network-based classifier for recognition are as follows:

[0053]

³²⁰ Step a: Calculate the Gaussian distribution information of all features in different gesture categories, that is, calculate all the mean and variance;

[0054]

³²⁵ Step b: For each input sample tested, find the probability of each feature in the gesture 1 category. Since each feature is independent of each other, the probability distribution under the feature also satisfies the independence, which can be obtained Find the total probability of the input sample in the gesture 1 category; and so on, find the different probabilities of the sample in all gesture categories;

[0055]

332 Step c: Compare the probability values of the input samples under different categories, find the category to which the maximum probability value belongs, and predict that the category is the category to which the input sample belongs.

[0056]

338 Step 6, execute the operation instruction; according to the gesture made in front of the binocular camera, the smart TV 4 executes the corresponding preset operation instruction to complete the human-computer interaction.

[0057]

344 The present invention provides a three-dimensional gesture control method for smart TV 4 based on binocular structured light. The present invention obtains high-quality three-dimensional information of both hands through the combination of binocular camera and infrared structured light, and then performs real-time gesture segmentation, detection and pointing. Pointer positioning, complete the real-time conversion of three-dimensional gesture actions and TV 4 instructions, and meet the real-time requirements of TV 4 man-machine interactive operation;

[0058]

353 Because the invention adopts the combination of binocular vision and structured light, it can effectively improve the environment's anti-interference ability and reduce the influence of light conditions on fingertip positioning. When indoors or when the environment is dim, the structured light is used to measure depth information , When the sun is strong, it turns to a pure binocular way.

357 Moreover, the calibration of binocular structured light has nothing to do with the laser, and it is more convenient to replace when the laser is damaged;

[0059]

362 The invention reduces the traversal range of the gesture detection by segmenting the foreground of the gesture image, and can meet the real-time requirements of the human-computer interaction operation of the TV 4.

[0060]

367 The basic principles, main features and advantages of the present invention have been shown and described above.

369 Those skilled in the industry should understand that the foregoing embodiments do not limit the present invention in any form, and all technical solutions obtained by equivalent substitutions or equivalent transformations fall within the protection scope of the present invention.

CLAIMS CN108363482A

1.

¹³ A method for controlling a smart TV with a three-dimensional gesture based on binocular structured light is characterized in that it comprises the following steps:

¹⁵ Step one, capture images; capture images in front of the camera through the binocular camera set in the smart TV, and store the collected left view and right view into the memory respectively, and then the processor processes the two images in the memory respectively;

¹⁸ Step two, reconstruct the image in three dimensions; according to the binocular matching algorithm, find the one-to-one correspondence between the pixels of the left view and the right view, and obtain the disparity map according to the abscissa difference of the pixel positions between them, and then according to the projection model With the principle of triangulation, the depth information of the original image is obtained;

²² Step three, preprocess the depth image; perform median filtering on the depth image to remove noise points, and then perform morphological processing on the internal holes in the depth image;

²⁴ Step 4: Detect the gesture image; analyze the obtained image depth data, separate the person from the background, select only the pixel information of the human body, and set all other pixel information to zero to obtain the depth image of the human body, and finally obtain the contour of the gesture ;

²⁷ Step 5: Recognize the three-dimensional gesture; extract the center distance feature of the gesture contour according to the obtained gesture contour. The center distance refers to the distance between the necessary point in the graph and each edge point; set the point $O(x_0, y_0)$ as the geometric center point of the gesture , The point set $C=\{(x_i, y_i)|i=1, 2, \dots, N\}$ is the edge contour of the gesture. It may be considered that the edge contour of the gesture is formed by connecting edge points. Therefore, the geometric center The point $O(x_0, y_0)$ and the center distance d can be calculated by the following formula:

³³ Combined with three-dimensional information, use the classifier based on Bayesian network for recognition;

³⁴ Step 6, execute the operation instruction; according to the gesture made in front of the binocular camera, the smart TV executes the corresponding preset operation instruction to complete the human-computer interaction.

2.

⁴⁰ The method for controlling a smart TV with a three-dimensional gesture based on binocular structured light according to claim 1, characterized in that, in step one, an image is acquired; Turn on the infrared laser; then capture the image in front of the camera through the binocular camera set in the smart TV, and store the collected left view and right view into the memory respectively, and then the processor processes the two images in the memory respectively.

3.

⁴⁸ The method for controlling a smart TV with a three-dimensional gesture based on binocular structured light according to claim 2, wherein if the infrared radiation intensity of the operating environment detected by the infrared detector is less than $0.2W/m^2 \cdot 850nm$, the infrared laser is turned on .

4.

⁵⁴ The method for controlling a smart TV with a three-dimensional gesture based on binocular structured light according to claim 1, wherein the morphological processing in the third step is to open the burr existing on the edge of the image and the internal cavity of the image. Close operation.

5.

⁶⁰ The method for controlling a smart TV with a three-dimensional gesture based on binocular structured light according to claim 1, wherein the specific steps of obtaining the outline of the gesture in the above step 4 are: reflecting the change point distance through the gray value of the pixel The distance of the lens is to calculate the gray distribution histogram of the depth image of the human body. The smaller peak of the gray histogram is the gray distribution of the hand area, and the larger peak is the gray distribution of the human torso, so as to segment the human body. Then use Canny edge operator to perform edge detection on the hand image of the hand image to obtain the contour of the gesture.

6.

⁷⁰ The method for controlling a smart TV with a three-dimensional gesture based on binocular structured light according to claim 1, wherein the specific steps of using a Bayesian network-based classifier to perform recognition in the above step 5 are as follows:

⁷³ Step a: Calculate the Gaussian distribution information of all features in different gesture categories, that is, calculate all the mean and variance;

⁷⁵ Step b: For each input sample tested, find the probability of each feature in the gesture 1 category. Since each feature is independent of each other, the probability distribution under the feature also satisfies the independence, which can be obtained Find the total probability of the input sample in the gesture 1 category; and so on, find the different probabilities of the sample in all gesture categories;

⁷⁹ Step c: Compare the probability values of the input samples under different categories, find the category to

which the maximum probability value belongs, and predict that the category is the category to which the input sample belongs.

Please find below and/or attached an Office communication concerning this application or proceeding.

The time period for reply, if any, is set in the attached communication.

Notice of the Office communication was sent electronically on above-indicated "Notification Date" to the following e-mail address(es):

USpatents@armstrongteasdale.com

DETAILED ACTION

Notice of Pre-AIA or AIA Status

The present application, filed on or after March 16, 2013, is being examined under the first inventor to file provisions of the AIA.

This is a first office action in response to an application for letters patent filed on 15 September 2021.

Claims 1-25 are presented for examination.

Information Disclosure Statement

The information disclosure statement (IDS) submitted on 09/15/2021 and 10/15/2021 was filed before the mailing date of the first office action on the merits. The submission is in compliance with the provisions of 37 CFR 1.97. Accordingly, the information disclosure statement is being considered by the examiner.

Claim Rejections - 35 USC § 112

The following is a quotation of 35 U.S.C. 112(b):

(b) **CONCLUSION.**—The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the inventor or a joint inventor regards as the invention.

The following is a quotation of 35 U.S.C. 112 (AIA), second paragraph:

The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention.

Claims 1, 23-24 are rejected under 35 U.S.C. 112(b) or 35 U.S.C. 112 (AIA), second paragraph, as being indefinite for failing to particularly point out and distinctly claim the subject matter which the inventor or a joint inventor (or for applications subject to AIA 35 U.S.C. 112, the applicant), regards as the invention.

Claims 1 and 24 relate to determining a longitudinal coordinate and a material property. It is neither clear how it is arrived at the desired distance feature and material feature nor which "further" filters are covered by the claim. The vague indication of correlation with one of the listed filters is an infinite definition of filters which does not allow to put into practice the invention or determine what is covered by the claims. The list of filters contains filters which are not commonly known and lack a definition in the claims. The sign in claim 10 is not defined.

As per claim 23, the detector as defined in claim 1 determines a material property, it is not clear how it can be used in an inertial measurement unit. the disclosure in this respect is also missing in the description.

Claim Objections

Claims 1-25 are objected to because of the following informalities: the parenthesis and numeral numbers are unnecessary. Appropriate correction is required.

Claim Rejections - 35 USC § 102

The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless –

(a)(1) the claimed invention was patented, described in a printed publication, or in public use, on sale, or otherwise available to the public before the effective filing date of the claimed invention.

Claim(s) 1-7, 9-16, and 24-25 are rejected under 35 U.S.C. 102(a)(1) as being anticipated by Schwartz et al. hereinafter Schwartz DE 19846619 A1.

As per claim 1, Schwartz teaches a detector for identifying at least one material property comprising - at least one sensor element comprising a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein the sensor element is configured for recording at least one reflection image of a light beam originating from at least one object (Schwartz: claim 1; CMOS sensor is a common matrix sensor);

- at least one evaluation device configured for determining the material property by evaluation of at least one beam profile of the reflection image (Schwartz: claim 1);

- intensity profile determination), wherein the evaluation device is configured for determining at least one distance feature by applying at least one distance dependent image filter to the reflection image, wherein the distance dependent image filter is at least one filter selected from the group consisting of: a depth-from-photon-ratio filter; a depth-from-defocus filter; or a linear combination thereof; or a further distance dependent image filter which correlates to the depth-from-photon-ratio filter and/or the depth-from-defocus filter or a linear combination thereof, being one of the depth-from-photon-ratio filter or the depth-from-defocus filter or a linear combination thereof, (Schwartz: claim 29); wherein the evaluation device is configured for determining at least one material feature by applying at least one material dependent image filter to the reflection image, wherein the material dependent image filter is at least one filter selected from the group consisting of: a luminance filter; a spot shape filter; a squared norm gradient; a standard deviation; a smoothness filter such as a Gaussian filter or median filter; a grey-level-occurrence-based contrast filter; a grey-level-occurrence-based energy filter; a grey-level-occurrence-based homogeneity filter; a grey-level-occurrence-based dissimilarity filter; a Law's energy filter; a threshold area filter; or a linear combination thereof; or a further material dependent image filter Mother which correlates to one or more of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof, being one of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof (Schwartz: claim 1, col. 14, lines 38-66), wherein the evaluation device is configured for determining a longitudinal coordinate and the material property by evaluating the distance feature and the material feature (Schwartz: claims 1 and 29).

The method according to claim 24 is disclosed in the same manner.

As per claim 25, a method of using the detector according to claim 1, relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a logistics application; a tracking application; an outdoor application; a mobile application; a communication application; a

Art Unit: 2454

photography application; a machine vision application; a robotics application; a quality control application; a manufacturing application (Schwartz: col 2, lines 31-38).

As per claim 2, Schwartz teaches the detector (110) according to claim 1, wherein the material dependent image filter is at least one filter that passes a hypothesis testing, wherein the hypothesis testing uses a Null-hypothesis that the filter does not distinguish between material classifiers and an alternative hypothesis that the filter distinguishes at least two material classifiers, wherein the filter passes the hypothesis testing if a p-value, p , is smaller or equal than a pre-defined level of significance (Schwartz: claim 1, col. 14, lines 38-66).

As per claim 3, Schwartz inherently teaches the detector (110) according to claim 1, wherein $p < 0.075$ (Schwartz: claim 1, col. 14, lines 38-66).

As per claim 4, Schwartz teaches the detector (110) according to claim 1, wherein the at least one material property is a property selected from the group consisting of: a scattering coefficient, a translucency, a transparency, a deviation from a Lambertian surface reflection, and a speckle (Schwartz column 14, lines 38-45; material properties are usually determined).

As per claim 5, Schwartz inherently teaches the detector (110) according to claim 1, wherein the further distance dependent image filter D_{10} other correlates to one or more of the distance dependent image filters by $p > 0.60$. (Schwartz: claim 1, col. 14, lines 38-66).

As per claim 6, Schwartz inherently teaches the detector (110) according to claim 1, wherein the further material dependent image filter D_{20} other correlates to one or more of the material dependent image filters D_m by ~~$|p_{D_{20} \text{ other}, D_m}| \geq 0.60$~~ , preferably by ~~$|p_{D_{20} \text{ other}, D_m}| \geq 0.80$~~ . (Schwartz: claim 1, col. 14, lines 38-66).

As per claim 7, Schwartz inherently teaches the detector (110) according to claim 1, wherein the material property m and/or the longitudinal coordinate z are determined by using a predetermined relationship between ... and z , m . (Schwartz: claim 1, col. 14, lines 38-66).

As per claim 9, Schwartz teaches the detector (110) according to claim 1, wherein the evaluation device (132) is configured for applying the distance dependent image filter and the material dependent image filter simultaneous to the reflection image (Schwartz: claim 1, col.

14, lines 38-66; Recursive, iterative or simultaneous application of filters and applying a further filter are considered usual alternatives).

As per claim 10, Schwartz teaches the detector (110) according to claim 1, wherein the evaluation device (132) is configured for determining whether at least one of $(I_t$ or O_2 is a function of the feature p_z or T_{im} of the other image filter or whether at least one of $\&P$ or $(T)_2$ is a function of the at least one other image filter, wherein the evaluation device (132) is configured for applying the distance dependent image filter and the material dependent image filter sequentially or recursively to the reflection image (Schwartz: claim 1, col. 14, lines 38-66; Recursive, iterative or simultaneous application of filters and applying a further filter are considered usual alternatives).

As per claim 11, Schwartz teaches the detector (110) according to claim 10 wherein the evaluation device (132) is configured for determining at least one of z and/or m by applying at least one further filter depending on at least one of $(I_z$ and y_{2m} to the reflection image (Schwartz: claim 1, col. 14, lines 38-66; Recursive, iterative or simultaneous application of filters and applying a further filter are considered usual alternatives).

As per claim 12, Schwartz teaches the detector (110) according to claim 1, wherein the depth-from-photon-ratio filter comprises evaluating a combined signal Q from at least two sensor signals of the sensor element (116), wherein the evaluation device (132) is configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals, wherein the evaluation device (132) is configured for using at least one predetermined relationship between the combined signal Q and the distance feature y_{iz} for determining the distance feature (see Schwartz claim 1; it's using combined signals from sensor elements or a convolution based algorithm are considered common measures).

As per claim 13, Schwartz teaches the detector (110) according to claim 1, wherein the depth-from-defocus filter comprises using at least one convolution-based algorithm such as a depth-from-defocus algorithm, wherein the evaluation device is configured for determining the distance feature y_{iz} by optimizing at least one blurring function f_b , wherein the blurring function is optimized by varying the parameters of the at least one blurring function (see Schwartz claim 1; it's using combined signals from sensor elements or a convolution based algorithm are considered common measures).

As per claim 14, Schwartz teaches the detector (110) according to claim 1, wherein the sensor element (116) comprises at least one CMOS sensor (see Schwartz claim 1, a CMOS sensor is a common matrix sensor).

As per claim 15, Schwartz teaches the detector (110) according to claim 1, wherein the detector (110) comprises at least one illumination source (124), wherein the illumination source (124) is configured for generating at least one illumination pattern for illumination of the object, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern; a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern; at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines; and at least one line pattern comprising ~~such as~~ parallel or crossing lines (Schwartz claim 7).

As per claim 16, Schwartz inherently teaches the detector (110) according to claim 15, wherein the illumination source (124) comprises at least one laser source and at least one diffractive optical element (Schwartz claim 1, a diffractive optical element is a usual means for producing such patterns).

Claim Rejections - 35 USC § 103

The following is a quotation of 35 U.S.C. 103 which forms the basis for all obviousness rejections set forth in this Office action:

A patent for a claimed invention may not be obtained, notwithstanding that the claimed invention is not identically disclosed as set forth in section 102, if the differences between the claimed invention and the prior art are such that the claimed invention as a whole would have been obvious before the effective filing date of the claimed invention to a person having ordinary skill in the art to which the claimed invention pertains. Patentability shall not be negated by the manner in which the invention was made.

The factual inquiries for establishing a background for determining obviousness under 35 U.S.C. 103 are summarized as follows:

1. Determining the scope and contents of the prior art.

2. Ascertaining the differences between the prior art and the claims at issue.
3. Resolving the level of ordinary skill in the pertinent art.
4. Considering objective evidence present in the application indicating obviousness or nonobviousness.

This application currently names joint inventors. In considering patentability of the claims the examiner presumes that the subject matter of the various claims was commonly owned as of the effective filing date of the claimed invention(s) absent any evidence to the contrary. Applicant is advised of the obligation under 37 CFR 1.56 to point out the inventor and effective filing dates of each claim that was not commonly owned as of the effective filing date of the later invention in order for the examiner to consider the applicability of 35 U.S.C. 102(b)(2)(C) for any potential 35 U.S.C. 102(a)(2) prior art against the later invention.

Claim(s) 8 and 22 are rejected under 35 U.S.C. 103 as being unpatentable over Schwartz and Bleyer et al. hereinafter Bleyer US PUB 20180033146.

As per claim 8, Schwartz does not teach The detector (110) according to claim 1, wherein the material property m and/or the longitudinal coordinate z are determined by a function Bleyer discusses intensity profile corrected based on distance (see claim 6 of Bleyer). It would be obvious to a skilled artisan at the effective date and time of the invention as claimed to incorporate Bleyer feature into Schwartz's system to facilitate precise position and modification.

As per claim 22, Schwartz does not discuss a camera (136) for imaging at least one object (112), the camera (136) comprising at least one detector (110) according to claim 1. Bleyer discloses this feature (see Bleyer, claim 1 and background of the invention). See claim 8 reasoning.

Claim(s) 17-20 are rejected under 35 U.S.C. 103 as being unpatentable over Schwartz and Schindler et al. hereinafter Schindler WO 2019042956 A1.

As per claim 17, Schwartz does not disclose the detector system (138) that further comprising at least one beacon device (140) adapted to direct at least one light beam towards the detector (110), wherein the beacon device (140) is at least one of attachable to the object (112), holdable by the object (112) and integratable into the object (112). Schindler teaches this feature (see Schindler claim 19). A skilled artisan will use a beacon just for implementation purpose.

As per claim 18, Schwartz does not teach a human-machine interface (142) for exchanging at least one item of information between a user (160) and a machine (168), wherein the human-machine interface (142) comprises at least one detector system (138) according to claim 17, wherein the at least one beacon device (140) is adapted to be at least one of directly or indirectly attached to the user (160) and held by the user (160), wherein the human-machine interface (142) is designed to determine at least one position of the user (160) by means of the detector system (138), wherein the human-machine interface (142) is designed to assign to the position at least one item of information. Schindler teaches these features (see Schindler claim 20).

As per claim 19, Schwartz does not teach an entertainment device (144) for carrying out at least one entertainment function, wherein the entertainment device (144) comprises at least one human-machine interface (142) according to claim 18, wherein the entertainment device (144) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (142), wherein the entertainment device (144) is designed to vary the entertainment function in accordance with the information. Schindler teaches these features (see Schindler claim 21).

As per claim 20, Schwartz does not teach a tracking system (146) for tracking a position of at least one movable object, the tracking system (146) comprising at least one detector system (138) according to claim 17 referring to a detector system, the tracking system (146) further comprising at least one track controller (170), wherein the track controller (170) is adapted to track a series of positions of the object (112) at specific points in time. Schindler teaches these features (see claim 22).

Claim(s) 21 is rejected under 35 U.S.C. 103 as being unpatentable over Schwartz and Jiangsu

CN108363482.

As per claim 21, Schwartz does not teach a scanning system (148) for determining a depth profile of a scenery, the scanning system (148) comprising at least one detector (110) according to claim 1, the scanning system (148) further comprising at least one illumination source adapted to scan the scenery with at least one light beam. Jiangsu teaches that feature (see Jiangsu claim 1).

Claim(s) 23 is rejected under 35 U.S.C. 103 as being unpatentable over Schwartz.

As per claim 23, Inertial measurement units are generally known, being adapted to receive data of a sensor as defined in claim 1, a material property detector, does not allow to establish a technical effect resulting from this feature.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to FRANTZ B JEAN whose telephone number is (571)272-3937. The examiner can normally be reached 8-5 M-F.

Examiner interviews are available via telephone, in-person, and video conferencing using a USPTO supplied web-based collaboration tool. To schedule an interview, applicant is encouraged to use the USPTO Automated Interview Request (AIR) at <http://www.uspto.gov/interviewpractice>.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Glenton B Burgess can be reached on 5712723949. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

The "Highest Number Previously Paid For" (Total or Independent) is the highest number found in the appropriate box in column 1.							

This collection of information is required by 37 CFR 1.16. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 12 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, VA 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. **SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, VA 22313-1450.**

If you need assistance in completing the form, call 1-800-PTO-9199 and select option 2.

Title:	DETECTOR FOR IDENTIFYING AT LEAST ONE MATERIAL PROPERTY		

November 13, 2023

AMENDMENT AND RESPONSE TO NON-FINAL OFFICE ACTION

TO THE COMMISSIONER FOR PATENTS:

In response to the Non-Final Office Action dated September 25, 2023, please consider the following remarks.

Amendments to the Claims begin on page 2.

Remarks begin on page 10.

Conclusion is on page 17.

AMENDMENTS TO THE CLAIMS

1. (Currently Amended) A detector $[(110)]$ for identifying at least one material property in comprising

at least one sensor element $[(116)]$ comprising a matrix $[(118)]$ of optical sensors $[(120)]$, the optical sensors $[(120)]$ each having a light-sensitive area $[(122)]$, wherein the sensor element $[(116)]$ is configured for recording at least one reflection image of a light beam originating from at least one object $[(112)]$, and

at least one evaluation device $[(132)]$ configured for determining the material property by evaluation of at least one beam profile of the reflection image,

wherein the evaluation device $[(132)]$ is configured for determining at least one distance feature φ_{1z} by applying at least one distance dependent image filter Φ_1 to the reflection image, wherein the distance dependent image filter is at least one filter selected from the group consisting of: a depth-from-photon-ratio filter; a depth-from-defocus filter, or a linear combination thereof; and a further distance dependent image filter Φ_{1other} which correlates to the depth-from-photon-ratio filter and/or the depth-from-defocus filter or a linear combination thereof by $|\rho_{\Phi_{1other}, \Phi_z}| \geq 0.40$ with Φ_z being one of the depth-from-photon-ratio filter or the depth-from-defocus filter or a linear combination thereof,

wherein the evaluation device $[(132)]$ is configured for determining at least one material feature φ_{2m} by applying at least one material dependent image filter Φ_2 to the reflection image, wherein the material dependent image filter is at least one filter selected from the group consisting of: a luminance filter; a spot shape filter; a squared norm gradient; a standard deviation; a smoothness filter; a Gaussian filter or median filter; a grey-level-occurrence-based contrast filter; a grey-level-occurrence-based energy filter; a grey-level-occurrence-based homogeneity filter; a grey-level-occurrence-based dissimilarity filter; a Law's energy filter; a threshold area filter; or a linear combination thereof; and a further material dependent image filter Φ_{2other} which correlates to one or more of the luminance filter, the spot shape filter, the squared norm gradient, the standard

deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof by $|\rho_{\Phi_{2\text{other}},\Phi_m}| \geq 0.40$ with Φ_m being one of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof, and

wherein the evaluation device **[(132)]** is configured for determining a longitudinal coordinate z and the material property m by evaluating the distance feature ϕ_{1z} and the material feature ϕ_{2m} .

2. (Currently Amended) The detector **[(110)]** according claim 1, wherein the material dependent image filter is at least one filter that passes a hypothesis testing, wherein the hypothesis testing uses a Null-hypothesis that the filter does not distinguish between material classifiers and an alternative hypothesis that the filter distinguishes at least two material classifiers, wherein the filter passes the hypothesis testing if a p-value, p , is smaller or equal than a pre-defined level of significance.

3. (Currently Amended) The detector **[(110)]** according to claim 1, wherein $p \leq 0.075$.

4. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the at least one material property is a property selected from the group consisting of: a scattering coefficient, a translucency, a transparency, a deviation from a Lambertian surface reflection, and a speckle.

5. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the further distance dependent image filter $\Phi_{1\text{other}}$ correlates to one or more of the distance dependent image filters Φ_z by $|\rho_{\Phi_{1\text{other}},\Phi_z}| \geq 0.60$.

6. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the further material dependent image filter $\Phi_{2\text{other}}$ correlates to one or more of the material dependent image filters Φ_m by $|\rho_{\Phi_{2\text{other}}, \Phi_m}| \geq 0.60$.

7. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the material property m and/or the longitudinal coordinate z are determined by using a predetermined relationship between ϕ_{1z} , ϕ_{2m} and z , m .

8. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the material property m and/or the longitudinal coordinate z are determined by a function $z(\phi_{1z}, \phi_{2m})$ and/or $m(\phi_{1z}, \phi_{2m})$.

9. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the evaluation device **[(132)]** is configured for applying the distance dependent image filter and the material dependent image filter simultaneous to the reflection image.

10. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the evaluation device **[(132)]** is configured for determining whether at least one of Φ_1 or Φ_2 is a function of the feature ϕ_{1z} or ϕ_{1m} or ϕ_{2m} of the other image filter or whether at least one of Φ_1 or Φ_2 is a function of the at least one other image filter, wherein the evaluation device **[(132)]** is configured for applying the distance dependent image filter and the material dependent image filter sequentially or recursively to the reflection image.

11. (Currently Amended) The detector **[(110)]** according to claim 10, wherein the evaluation device **[(132)]** is configured for determining at least one of z and/or m by applying at least one further filter depending on at least one of ϕ_{1z} and ϕ_{2m} to the reflection image.

12. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the depth-from-photon-ratio filter comprises evaluating a combined signal Q from at least two sensor signals of the sensor element **[(116)]**, wherein the evaluation device **[(132)]** is configured for deriving the combined signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals, wherein the evaluation device **[(132)]** is configured for using at least

one predetermined relationship between the combined signal Q and the distance feature ϕ_{1z} for determining the distance feature ϕ_{1z} .

13. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the depth-from-defocus filter comprises using at least one convolution-based algorithm such as a depth-from-defocus algorithm, wherein the evaluation device is configured for determining the distance feature ϕ_{1z} by optimizing at least one blurring function f_a , wherein the blurring function is optimized by varying the parameters of the at least one blurring function.

14. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the sensor element **[(116)]** comprises at least one CMOS sensor.

15. (Currently Amended) The detector **[(110)]** according to claim 1, wherein the detector **[(110)]** comprises at least one illumination source **[(124)]**, wherein the illumination source **[(124)]** is configured for generating at least one illumination pattern for illumination of the object, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern; a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern, at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern; at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines; and at least one line pattern comprising parallel or crossing lines.

16. (Currently Amended) The detector **(110)** according to claim 15, wherein the illumination source **[(124)]** comprises at least one laser source and at least one diffractive optical element.

17. (Currently Amended) A detector system **[(138)]**, the detector system **[(138)]** comprising at least one detector **[(110)]** according to claim 1, the detector system **[(138)]** further comprising at least one beacon device **[(140)]** adapted to direct

at least one light beam towards the detector **[[110]]**, wherein the beacon device **[[140]]** is at least one of attachable to the object **[[112]]**, holdable by the object **[[112]]** and integratable into the object **[[112]]**.

18. (Currently Amended) A human-machine interface **[[142]]** for exchanging at least one item of information between a user **[[160]]** and a machine **[[168]]**, wherein the human-machine interface **[[142]]** comprises at least one detector system **[[138]]** according to claim 17, wherein the at least one beacon device **[[140]]** is adapted to be at least one of directly or indirectly attached to the user **[[160]]** and held by the user **[[160]]**, wherein the human-machine interface **[[142]]** is designed to determine at least one position of the user **[[160]]** by means of the detector system **[[138]]**, wherein the human-machine interface **[[142]]** is designed to assign to the position at least one item of information.

19. (Currently Amended) An entertainment device **[[144]]** for carrying out at least one entertainment function, wherein the entertainment device **[[144]]** comprises at least one human-machine interface **[[142]]** according to claim 18, wherein the entertainment device **[[144]]** is designed to enable at least one item of information to be input by a player by means of the human-machine interface **[[142]]**, wherein the entertainment device **[[144]]** is designed to vary the entertainment function in accordance with the information.

20. (Currently Amended) A tracking system **[[146]]** for tracking a position of at least one movable object, the tracking system **[[146]]** comprising at least one detector system **[[138]]** according to claim 17 referring to a detector system, the tracking system **[[146]]** further comprising at least one track controller **[[170]]**, wherein the track controller **[[170]]** is adapted to track a series of positions of the object **[[112]]** at specific points in time.

21. (Currently Amended) A scanning system **[[148]]** for determining a depth profile of a scenery, the scanning system **[[148]]** comprising at least one detector **[[110]]** according to claim 1, the scanning system **[[148]]** further comprising at least one illumination source adapted to scan the scenery with at least one light beam.

22. (Currently Amended) A camera [(136)] for imaging at least one object [(112)], the camera [(136)] comprising at least one detector [(110)] according to claim 1.

23. (Currently Amended) An inertial measurement unit [(172)] for use in an electronic device, wherein the inertial measurement unit [(172)] is adapted to receive data determined by at least one detector [(110)] according to claim 1, wherein the inertial measurement unit [(172)] further is adapted to receive data determined by at least one further sensor selected from the group consisting of: a wheel speed sensor, a turn rate sensor, an inclination sensor, an orientation sensor, a motion sensor, a magneto hydro dynamic sensor, a force sensor, an angular sensor, an angular rate sensor, a magnetic field sensor, a magnetometer, an accelerometer, and a gyroscope, wherein the inertial measurement unit is adapted to determine by evaluating the data from the detector and the at least one further sensor at least one property of the electronic device selected from the group consisting of: position in space, relative or absolute motion in space, rotation, acceleration, orientation, angle position, inclination, turn rate, and speed.

24. (Currently Amended) A method for determining at least one material property of at least one object [(112)] by using at least one detector [(110)] according to claim 1, the method comprising the following steps:

a) determining at least one reflection image of the object [(112)] by using at least one sensor element [(116)] having a matrix [(118)] of optical sensors [(120)], the optical sensors [(120)] each having a light-sensitive area [(122)]; and

b) determining the material property by evaluating at least one beam profile of the reflection image by using at least one evaluation device [(132)], wherein the evaluating comprises:

b1) determining at least one distance feature ϕ_{1z} by applying at least one distance dependent image filter Φ_1 to the reflection image, wherein the distance dependent image filter is at least one filter selected from the group consisting of: a depth-from-photon-ratio filter; a depth-from-defocus filter; or a linear combination thereof and a further distance

dependent image filter Φ_{1other} which correlates to the depth-from-photon-ratio filter and/or the depth-from-defocus filter or a linear combination thereof by $|\rho_{\Phi_{1other}, \Phi_z}| \geq 0.40$ with Φ_z being one of the depth-from-photon-ratio filter or the depth-from-defocus filter or a linear combination thereof,

b2) determining at least one material feature φ_{2m} by applying at least one material dependent image filter Φ_2 to the reflection image, wherein the material dependent image filter is at least one filter selected from the group consisting of: a luminance filter; a spot shape filter; a squared norm gradient; a standard deviation; a smoothness filter; a Gaussian filter or median filter; a grey-level-occurrence-based contrast filter; a grey-level-occurrence-based energy filter; a grey-level-occurrence-based homogeneity filter; a grey-level-occurrence-based dissimilarity filter; a Law's energy filter; a threshold area filter; or a linear combination thereof; and a further material dependent image filter Φ_{2other} which correlates to one or more of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof by $|\rho_{\Phi_{2other}, \Phi_m}| \geq 0.40$ with Φ_m being one of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof, and

b3) determining a longitudinal coordinate z and the material property m by evaluating the distance feature φ_{1z} and the material feature φ_{2m} .

25. (Currently Amended) A method of using the detector **[(110)]** according to claim 1, the method comprising using the detector **[(110)]** for a purpose of use selected from the group consisting of: a position measurement in traffic technology; an entertainment application, a security application; a surveillance application, a safety application, a human-machine interface application; a logistics application; a tracking

application; an outdoor application; a mobile application; a communication application; a photography application; a machine vision application; a robotics application; a quality control application; and a manufacturing application.

REMARKS

I. Status of the Claims

Claims 1-25 are amended for clarity.

Claims 1-25 are pending and under examination. No new matter is added herein.

II. Rejection under 35 U.S.C. § 112

Claim 1, 23 and 24 stand rejected under 35 U.S.C. § 112(b) as allegedly being indefinite.

Applicant respectfully submits that claims 1 and 24 as recited are clear and definite.

The Office based the rejections in part on, “Claims 1 and 24 relate to determining a longitudinal coordinate and a material property. It is neither clear how it is arrived at the desired distance feature and material feature nor which "further" filters are covered by the claim. The vague indication of correlation with one of the listed filters is an infinite definition of filters which does not allow to put into practice the invention or determine what is covered by the claims. The list of filters contains filters which are not commonly known and lack a definition in the claims. The sign in claim 10 is not defined.” (see Page 3 of the Office Action dated 09/25/2023).

Without commenting on the appropriateness of the rejection regarding claim 10, claim 10 has been amended by correcting “ φ_{1m} ” to “ φ_{2m} ” to make it consistent with the other claims and the description. Accordingly, Applicant respectfully submits that amended claim 10 is clear and definite.

With respect to claim 23, Applicant respectfully submits that the claim requires that “the inertial measurement unit is adapted to receive data determined by at least one detector according to claim 1,” and also “the inertial measurement unit is adapted to determine by evaluating the data from the detector and the at least one further sensor at least one property.” Thus, in contrast to the assertions of the Office, it is

clear that the inertial measurement unit of claim 23 receives data and evaluates that data, in combination with further data, for its measurement. Thus, claim 23 is definite.

With respect to claims 1 and 24, Applicant respectfully submits that the further filters are described in each recitation by a functional correlation. These functional correlations also indicate how the longitudinal coordinates and material properties are determined. Applicant also respectfully submits that these functional correlations properly define the claim scope and should not be unduly restricted by the requirement of structure. Finally, Applicant also respectfully submits that the filters recited in the present claims are known to a person having ordinary skill in the art, in contrast to the Office's assertions that they are not commonly known. Thus, claims 1 and 24 are definite.

Moreover, reference is made herein to the description given on starting of page 15 to page 23 of the application as-filed, which provides a clear and detailed explanation regarding the distance dependent image filters. A detailed description of the determining of the material feature and the listed filters is given in the present application as-filed starting on page 24. A detailed description of Pearson correlation coefficients is found in the present application as-filed at page 15. These descriptions inform the present claims and support their definiteness.

In view of the foregoing, Applicant respectfully requests withdrawal of the rejection and allowance of the claims.

III. Claim Objections

Claims 1-25 are objected to because of informalities.

Claims 1-25 are amended herein consistent with the comments of the Office. It is believed these amendments overcome the objections.

IV. Rejections under 35 U.S.C. § 102

Claim(s) 1-7, 9-16, and 24-25 are rejected under 35 U.S.C. 102(a)(1) as allegedly being unpatentable over DE Patent Application Publication No. 19846619 A1 (Schwartz).

Applicant respectfully disagrees and submits that claims 1-7, 9-16, and 24-25 are novel and patentable over Schwartz.

Schwartz fails to teach or suggest at least the following features of claim 1:

a. wherein the evaluation device (132) is configured for determining at least one distance feature ϕ_{1z} by applying at least one distance dependent image filter ϕ_1 to the reflection image, wherein the distance dependent image filter is at least one filter selected from the group consisting of: a depth-from-photon-ratio filter; a depth-from-defocus filter; or a linear combination thereof; or a further distance dependent image filter ϕ_1 other which correlates to the depth-from-photon-ratio filter and/or the depth-from-defocus filter or a linear combination thereof by $|\rho_{\phi_1 \text{ other}, \Phi_z}| \geq 0.40$ with Φ_z being one of the depth-from-photon-ratio filter or the depth-from-defocus filter or a linear combination thereof;

b. wherein the evaluation device (132) is configured for determining at least one material feature ϕ_{2m} by applying at least one material dependent image filter Φ_2 to the reflection image, wherein the material dependent image filter is at least one filter selected from the group consisting of: a luminance filter; a spot shape filter; a squared norm gradient; a standard deviation; a smoothness filter such as a Gaussian filter or median filter; a grey-level-occurrence-based contrast filter; a grey-level-occurrence-based energy filter; a grey-level-occurrence-based homogeneity filter; a grey-level-occurrence-based dissimilarity filter; a Law's energy filter; a threshold area filter; or a linear combination thereof; or a further material dependent image filter Φ_2 other which correlates to one or more of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof by $|\rho_{\Phi_2 \text{ other}, \Phi_m}| \geq 0.40$ with Φ_m being one of the luminance filter, the spot shape filter,

the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof.

The present application describes using **beam profile analysis** for determining a material property of an object. Usual image filters which can be used for beam profile analysis yield features that depend on both distance and material such that reliable identification and classification of the material is not possible. However, it was found that the listed image filters of claim 1 of the present application allow reliable identification and classification of the material.

As mentioned above, Schwartz fails to disclose feature a). In contrast to using a distance dependent filter such as a depth-from-photon-ratio filter, a depth-from-defocus filter or a further correlated distance dependent image filter, Schwartz describes determining **depth information** by using structured light techniques based on triangulation. However, these techniques cannot be considered as distance dependent image filter according to claim 1, i.e. depth-from-defocus or depth-from-photon or a correlated image filter. Thus, Schwartz is deficient at least for this reason.

With respect to feature b), Schwartz describes determining **reflectivity information**. However, it describes different techniques as recited in claim 1 of the present application. Schwartz describes a variety of different methods for determining a "structure surface appearance quality", however, none of the disclosed methods relates to determining a material feature by applying at least one material dependent image filter of the list given in claim 1. Accordingly, claims 1-7, 9-16, and 24-25 are novel and patentable over Schwartz.

In view of the foregoing, Applicant respectfully requests withdrawal of the rejections and allowance of the claims.

V. Rejections under 35 U.S.C. § 103

i. Claims 8 and 22 stand rejected under 35 U.S.C. 103 as allegedly being unpatentable over DE Patent Application Publication No. 19846619 A1 (Schwartz), and in view of US Patent Application Publication No. 20180033146 (Bleyer).

Applicants respectfully submits that claims 8 and 22 are patentable over Schwartz and Bleyer.

The Office based the rejections in part on, “As per claim 8, Schwartz does not teach the detector (110) according to claim 1, wherein the material property m and/or the longitudinal coordinate z are determined by a function... Bleyer discusses intensity profile corrected based on distance (see claim 6 of Bleyer). It would be obvious to a skilled artisan at the effective date and time of the invention as claimed to incorporate Bleyer feature into Schwartz’s system to facilitate precise position and modification” (see Page 8 of the Office Action dated 09/25/23).

The Office based the further rejections in part on, “As per claim 22, Schwartz does not discuss a camera (136) for imaging at least one object (112), the camera (136) comprising at least one detector (110) according to claim 1. Bleyer discloses this feature (see Bleyer, claim 1 and background of the invention). See claim 8 reasoning” (see Page 8 of the Office Action dated 09/25/23).

Applicant respectfully disagrees. Claims 8 and 22 depend from claim 1, and therefore claims 8 and 22 are patentable over Schwartz at least for the same reasons outlined above.

Bleyer does not cure the deficiencies of Schwartz. As outlined above, the distinguishing features a) and b) of the present application have the **synergistic technical effect** of allowing for reliably identifying at least one material property of an object. On the contrary, neither Schwartz nor Bleyer describe a technique based on beam profile analysis. Thus, Schwartz and Bleyer are deficient for at least this reason.

The objective technical problem to be solved would be increasing reliability for identifying at least one material property of an object. Starting from Schwartz, the skilled person, firstly, would have to modify the device and the disclosed method to use beam

profile analysis for identifying a material property. In a further step, the skilled person would have to notice that there are problems with image filters, and in an even further step, the skilled person would have to find the image filters solving the above-mentioned problem. However, the skilled person has no motivation for any of the named steps when starting with Schwartz and Bleyer.

Accordingly, it would not have been obvious to a person having ordinary skill in the art to modify Schwartz and Bleyer with elements not taught or suggested in Schwartz or Bleyer in order to arrive at the present claims. There is no teaching, suggestion, motivation, or other reason in Schwartz and Bleyer to make such modifications. Such modifications would require impermissible hindsight and could only have been arrived at by using the present application as a roadmap.

In view of the foregoing, Applicant respectfully requests withdrawal of the rejections and allowance of the claims.

ii. Claim 17-20 stand rejected under 35 U.S.C. 103 as allegedly being unpatentable over DE Patent Application Publication No. 19846619 A1 (Schwartz), and in view of WO Patent Application Publication No. 2019042956 A1 (Schindler).

Applicants respectfully submits that claims 17-20 are patentable over Schwartz and Schindler.

Claims 17-20 depend from claim 1, and are therefore patentable over Schwartz at least for the reasons set forth above.

Schindler does not cure the deficiencies of Schwartz. The Office relied on Schindler for allegedly teaching a detector system (138) that further comprising at least one beacon device (140), a human-machine interface (142) for exchanging at least one item of information between a user (160) and a machine (168), entertainment device (144) and a tracking system (146). See Page 9 of the Office Action dated 09/25/23.

However, without conceding to any assertions of the Office, Applicant respectfully submits that Schindler does not teach or suggest all the elements of claim 1 from which

claims 17 and 18-20 depend, and the Office has not cited Schindler as such. Thus, Schindler is deficient at least for this reason.

In view of the foregoing, Applicant respectfully requests withdrawal of the rejections and allowance of the claims.

iii. Claim 21 stands rejected under 35 U.S.C. 103 as allegedly being unpatentable over DE Patent Application Publication No. 19846619 A1 (Schwartz)), and in view of CN Patent Application Publication No. 108363482 (Jiangsu).

Applicants respectfully submits that claim 21 is patentable over Schwartz and Jiangsu.

Claim 21 depends from claim 1, and is therefore patentable over Schwartz at least for the reasons set forth above.

Jiangsu does not cure the deficiencies of Schwartz. The Office based the rejections in part on, “As per claim 21, Schwartz does not teach a scanning system (148) for determining a depth profile of a scenery, the scanning system (148) comprising at least one detector (110) according to claim 1, the scanning system (148) further comprising at least one illumination source adapted to scan the scenery with at least one light beam. Jiangsu teaches that feature (see Jiangsu clam 1)” (see Page 10 of the Office Action dated 09/25/23).

However, without conceding to any assertions of the Office, Applicant respectfully submits that Jiangsu does not teach or suggest all the elements of claim 1 from which 21 depends, and the Office has not cited Jiangsu as such. Thus, Jiangsu is deficient at least for this reason.

In view of the foregoing, Applicant respectfully requests withdrawal of the rejections and allowance of the claims.

iv. Claim 23 stands rejected under 35 U.S.C. 103 as allegedly being unpatentable over DE Patent Application Publication No. 19846619 A1 (Schwartz).

Applicants respectfully submits that claim 23 is patentable over Schwartz.

The Office based the rejections in part on, “As per claim 23, Inertial measurement units are generally known, being adapted to receive data of a sensor as defined in claim 1, a material property detector, does not allow to establish a technical effect resulting from this feature” (see Page 10 of the Office Action dated 09/25/23).

Claim 23 depends from claim 1, and is therefore patentable over Schwartz at least for the reasons set forth above.

In view of the foregoing, Applicant respectfully requests withdrawal of the rejections and allowance of the claims.

CONCLUSION

Applicant requests reconsideration and allowance of all pending claims. Applicant authorizes the Commissioner to charge any fees due in connection with this response to Deposit Account No. 01-2384 in the name of Armstrong Teasdale LLP. Please reference docket number 27843-1809.

Respectfully submitted,

/Christopher M. Goff/

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the

International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

ART UNIT

PAPER NUMBER

2454

DATE MAILED: 12/01/2023

APPLICATION NO.	FILING DATE	FIRST NAMED INVENTOR	ATTORNEY DOCKET NO.	CONFIRMATION NO.
17/439,492	09/15/2021	Friedrich Schick	27843-1809 182037US01	9002

TITLE OF INVENTION: DETECTOR FOR IDENTIFYING AT LEAST ONE MATERIAL PROPERTY

APPLN. TYPE	ENTITY STATUS	ISSUE FEE DUE	PUBLICATION FEE DUE	PREV. PAID ISSUE FEE	TOTAL FEE(S) DUE	DATE DUE
nonprovisional	UNDISCOUNTED	\$1200	\$0.00	\$0.00	\$1200	03/01/2024

THE APPLICATION IDENTIFIED ABOVE HAS BEEN EXAMINED AND IS ALLOWED FOR ISSUANCE AS A PATENT. PROSECUTION ON THE MERITS IS CLOSED. THIS NOTICE OF ALLOWANCE IS NOT A GRANT OF PATENT RIGHTS. THIS APPLICATION IS SUBJECT TO WITHDRAWAL FROM ISSUE AT THE INITIATIVE OF THE OFFICE OR UPON PETITION BY THE APPLICANT. SEE 37 CFR 1.313 AND MPEP 1308.

THE ISSUE FEE AND PUBLICATION FEE (IF REQUIRED) MUST BE PAID WITHIN THREE MONTHS FROM THE MAILING DATE OF THIS NOTICE OR THIS APPLICATION SHALL BE REGARDED AS ABANDONED. THIS STATUTORY PERIOD CANNOT BE EXTENDED. SEE 35 U.S.C. 151. THE ISSUE FEE DUE INDICATED ABOVE DOES NOT REFLECT A CREDIT FOR ANY PREVIOUSLY PAID ISSUE FEE IN THIS APPLICATION. IF AN ISSUE FEE HAS PREVIOUSLY BEEN PAID IN THIS APPLICATION (AS SHOWN ABOVE), THE RETURN OF PART B OF THIS FORM WILL BE CONSIDERED A REQUEST TO REAPPLY THE PREVIOUSLY PAID ISSUE FEE TOWARD THE ISSUE FEE NOW DUE.

HOW TO REPLY TO THIS NOTICE:

I. Review the ENTITY STATUS shown above. If the ENTITY STATUS is shown as SMALL or MICRO, verify whether entitlement to that entity status still applies.

If the ENTITY STATUS is the same as shown above, pay the TOTAL FEE(S) DUE shown above.

If the ENTITY STATUS is changed from that shown above, on PART B - FEE(S) TRANSMITTAL, complete section number 5 titled "Change in Entity Status (from status indicated above)".

For purposes of this notice, small entity fees are 40% the amount of undiscounted fees, and micro entity fees are 20% the amount of undiscounted fees.

II. PART B - FEE(S) TRANSMITTAL, or its equivalent, must be completed and returned to the United States Patent and Trademark Office (USPTO) with your ISSUE FEE and PUBLICATION FEE (if required). If you are charging the fee(s) to your deposit account, section "4b" of Part B - Fee(s) Transmittal should be completed. If an equivalent of Part B is filed, a request to reapply a previously paid issue fee must be clearly made, and delays in processing may occur due to the difficulty in recognizing the paper as an equivalent of Part B.

III. All communications regarding this application must give the application number. Please direct all communications prior to issuance to Mail Stop ISSUE FEE unless advised to the contrary.

IMPORTANT REMINDER: Maintenance fees are due in utility patents issuing on applications filed on or after Dec. 12, 1980. It is patentee's responsibility to ensure timely payment of maintenance fees when due. More information is available at www.uspto.gov/PatentMaintenanceFees.

PART B - FEE(S) TRANSMITTAL

Complete and send this form, together with applicable fee(s), by mail or fax, or via the USPTO patent electronic filing system.

By mail, send to: Mail Stop ISSUE FEE
Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450

By fax, send to: (571)-273-2885

INSTRUCTIONS: This form should be used for transmitting the ISSUE FEE and PUBLICATION FEE (if required). Blocks 1 through 5 should be completed where appropriate. All further correspondence will be mailed to the current correspondence address as indicated unless corrected below or directed otherwise in Block 1, by (a) specifying a new correspondence address; and/or (b) indicating a separate "FEE ADDRESS" for maintenance fee notifications. **Because electronic patent issuance may occur shortly after issue fee payment, any desired continuing application should preferably be filed prior to payment of this issue fee in order not to jeopardize copendency.**

CURRENT CORRESPONDENCE ADDRESS (Note: Use Block 1 for any change of address)

Note: A certificate of mailing can only be used for domestic mailings of the Fee(s) Transmittal. This certificate cannot be used for any other accompanying papers. Each additional paper, such as an assignment or formal drawing, must have its own certificate of mailing or transmission.

76656 7590 12/01/2023

JEAN, FRANTZ B	2454	348-135000

1. Change of correspondence address or indication of "Fee Address" (37 CFR 1.363).

☐ Change of correspondence address (or Change of Correspondence Address form PTO/AIA/122 or PTO/SB/122) attached.

☐ "Fee Address" indication (or "Fee Address" Indication form PTO/AIA/47 or PTO/SB/47; Rev 03-02 or more recent) attached. **Use of a Customer Number is required.**

2. For printing on the patent front page, list

(1) The names of up to 3 registered patent attorneys or agents OR, alternatively,

1 _____

(2) The name of a single firm (having as a member a registered attorney or agent) and the names of up to 2 registered patent attorneys or agents. If no name is listed, no name will be printed.

2 _____

3 _____

3. ASSIGNEE NAME AND RESIDENCE DATA TO BE PRINTED ON THE PATENT (print or type)

PLEASE NOTE: Unless an assignee is identified below, no assignee data will appear on the patent. If an assignee is identified below, the document must have been previously recorded, or filed for recordation, as set forth in 37 CFR 3.11 and 37 CFR 3.81(a). Completion of this form is NOT a substitute for filing an assignment.

(A) NAME OF ASSIGNEE

(B) RESIDENCE: (CITY and STATE OR COUNTRY)

Please check the appropriate assignee category or categories (will not be printed on the patent) : ☐ Individual ☐ Corporation or other private group entity ☐ Government

4a. Fees submitted: ☐ Issue Fee ☐ Publication Fee (if required)

4b. Method of Payment: (Please first reapply any previously paid fee shown above)

☐ Electronic Payment via the USPTO patent electronic filing system ☐ Enclosed check ☐ Non-electronic payment by credit card (Attach form PTO-2038)

☐ The Director is hereby authorized to charge the required fee(s), any deficiency, or credit any overpayment to Deposit Account No. _____

5. Change in Entity Status (from status indicated above)

☐ Applicant certifying micro entity status. See 37 CFR 1.29

☐ Applicant asserting small entity status. See 37 CFR 1.27

☐ Applicant changing to regular undiscounted fee status.

NOTE: Absent a valid certification of Micro Entity Status (see forms PTO/SB/15A and 15B), issue fee payment in the micro entity amount will not be accepted at the risk of application abandonment.

NOTE: If the application was previously under micro entity status, checking this box will be taken to be a notification of loss of entitlement to micro entity status.

NOTE: Checking this box will be taken to be a notification of loss of entitlement to small or micro entity status, as applicable.

NOTE: This form must be signed in accordance with 37 CFR 1.31 and 1.33. See 37 CFR 1.4 for signature requirements and certifications.

Determination of Patent Term Adjustment under 35 U.S.C. 154 (b) (Applications filed on or after May 29, 2000)

The Office has discontinued providing a Patent Term Adjustment (PTA) calculation with the Notice of Allowance.

Section 1(h)(2) of the AIA Technical Corrections Act amended 35 U.S.C. 154(b)(3)(B)(i) to eliminate the requirement that the Office provide a patent term adjustment determination with the notice of allowance. See Revisions to Patent Term Adjustment, 78 Fed. Reg. 19416, 19417 (Apr. 1, 2013). Therefore, the Office is no longer providing an initial patent term adjustment determination with the notice of allowance. The Office will continue to provide a patent term adjustment determination with the Issue Notification Letter that is mailed to applicant approximately three weeks prior to the issue date of the patent, and will include the patent term adjustment on the patent. Any request for reconsideration of the patent term adjustment determination (or reinstatement of patent term adjustment) should follow the process outlined in 37 CFR 1.705.

Any questions regarding the Patent Term Extension or Adjustment determination should be directed to the Office of Patent Legal Administration at (571)-272-7702. Questions relating to issue and publication fee payments should be directed to the Customer Service Center of the Office of Patent Publication at 1-(888)-786-0101 or (571)-272-4200.

OMB Clearance and PRA Burden Statement for PTOL-85 Part B

The Paperwork Reduction Act (PRA) of 1995 requires Federal agencies to obtain Office of Management and Budget approval before requesting most types of information from the public. When OMB approves an agency request to collect information from the public, OMB (i) provides a valid OMB Control Number and expiration date for the agency to display on the instrument that will be used to collect the information and (ii) requires the agency to inform the public about the OMB Control Number's legal significance in accordance with 5 CFR 1320.5(b).

The information collected by PTOL-85 Part B is required by 37 CFR 1.311. The information is required to obtain or retain a benefit by the public which is to file (and by the USPTO to process) an application. Confidentiality is governed by 35 U.S.C. 122 and 37 CFR 1.14. This collection is estimated to take 30 minutes to complete, including gathering, preparing, and submitting the completed application form to the USPTO. Time will vary depending upon the individual case. Any comments on the amount of time you require to complete this form and/or suggestions for reducing this burden, should be sent to the Chief Information Officer, U.S. Patent and Trademark Office, U.S. Department of Commerce, P.O. Box 1450, Alexandria, Virginia 22313-1450. DO NOT SEND FEES OR COMPLETED FORMS TO THIS ADDRESS. SEND TO: Commissioner for Patents, P.O. Box 1450, Alexandria, Virginia 22313-1450. Under the Paperwork Reduction Act of 1995, no persons are required to respond to a collection of information unless it displays a valid OMB control number.

Privacy Act Statement

The Privacy Act of 1974 (P.L. 93-579) requires that you be given certain information in connection with your submission of the attached form related to a patent application or patent. Accordingly, pursuant to the requirements of the Act, please be advised that: (1) the general authority for the collection of this information is 35 U.S.C. 2(b)(2); (2) furnishing of the information solicited is voluntary; and (3) the principal purpose for which the information is used by the U.S. Patent and Trademark Office is to process and/or examine your submission related to a patent application or patent. If you do not furnish the requested information, the U.S. Patent and Trademark Office may not be able to process and/or examine your submission, which may result in termination of proceedings or abandonment of the application or expiration of the patent.

The information provided by you in this form will be subject to the following routine uses:

1. The information on this form will be treated confidentially to the extent allowed under the Freedom of Information Act (5 U.S.C. 552) and the Privacy Act (5 U.S.C. 552a). Records from this system of records may be disclosed to the Department of Justice to determine whether disclosure of these records is required by the Freedom of Information Act.
2. A record from this system of records may be disclosed, as a routine use, in the course of presenting evidence to a court, magistrate, or administrative tribunal, including disclosures to opposing counsel in the course of settlement negotiations.
3. A record in this system of records may be disclosed, as a routine use, to a Member of Congress submitting a request involving an individual, to whom the record pertains, when the individual has requested assistance from the Member with respect to the subject matter of the record.
4. A record in this system of records may be disclosed, as a routine use, to a contractor of the Agency having need for the information in order to perform a contract. Recipients of information shall be required to comply with the requirements of the Privacy Act of 1974, as amended, pursuant to 5 U.S.C. 552a(m).
5. A record related to an International Application filed under the Patent Cooperation Treaty in this system of records may be disclosed, as a routine use, to the International Bureau of the World Intellectual Property Organization, pursuant to the Patent Cooperation Treaty.
6. A record in this system of records may be disclosed, as a routine use, to another federal agency for purposes of National Security review (35 U.S.C. 181) and for review pursuant to the Atomic Energy Act (42 U.S.C. 218(c)).
7. A record from this system of records may be disclosed, as a routine use, to the Administrator, General Services, or his/her designee, during an inspection of records conducted by GSA as part of that agency's responsibility to recommend improvements in records management practices and programs, under authority of 44 U.S.C. 2904 and 2906. Such disclosure shall be made in accordance with the GSA regulations governing inspection of records for this purpose, and any other relevant (i.e., GSA or Commerce) directive. Such disclosure shall not be used to make determinations about individuals.
8. A record from this system of records may be disclosed, as a routine use, to the public after either publication of the application pursuant to 35 U.S.C. 122(b) or issuance of a patent pursuant to 35 U.S.C. 151. Further, a record may be disclosed, subject to the limitations of 37 CFR 1.14, as a routine use, to the public if the record was filed in an application which became abandoned or in which the proceedings were terminated and which application is referenced by either a published application, an application open to public inspection or an issued patent.
9. A record from this system of records may be disclosed, as a routine use, to a Federal, State, or local law enforcement agency, if the USPTO becomes aware of a violation or potential violation of law or regulation.

Notice of Allowability	Application No. 17/439,492	Applicant(s) Schick et al.	
	Examiner FRANTZ B JEAN	Art Unit 2454	AIA (FITF) Status Yes

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address--

All claims being allowable, PROSECUTION ON THE MERITS IS (OR REMAINS) CLOSED in this application. If not included herewith (or previously mailed), a Notice of Allowance (PTOL-85) or other appropriate communication will be mailed in due course. **THIS NOTICE OF ALLOWABILITY IS NOT A GRANT OF PATENT RIGHTS.** This application is subject to withdrawal from issue at the initiative of the Office or upon petition by the applicant. See 37 CFR 1.313 and MPEP 1308.

1. ☒ This communication is responsive to the amendment filed on 13 November 2023.
☐ A declaration(s)/affidavit(s) under **37 CFR 1.130(b)** was/were filed on _____.

2. ☐ An election was made by the applicant in response to a restriction requirement set forth during the interview on _____; the restriction requirement and election have been incorporated into this action.

3. ☒ The allowed claim(s) is/are 1-25. As a result of the allowed claim(s), you may be eligible to benefit from the **Patent Prosecution Highway** program at a participating intellectual property office for the corresponding application. For more information, please see http://www.uspto.gov/patents/init_events/pph/index.jsp or send an inquiry to PPHfeedback@uspto.gov.

4. ☒ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).

Certified copies:

a) ☒ All b) ☐ Some* c) ☐ None of the:

1. ☒ Certified copies of the priority documents have been received.

2. ☐ Certified copies of the priority documents have been received in Application No. _____.

3. ☐ Copies of the certified copies of the priority documents have been received in this national stage application from the International Bureau (PCT Rule 17.2(a)).

* Certified copies not received: _____.

Applicant has THREE MONTHS FROM THE "MAILING DATE" of this communication to file a reply complying with the requirements noted below. Failure to timely comply will result in ABANDONMENT of this application.
THIS THREE-MONTH PERIOD IS NOT EXTENDABLE.

5. ☐ CORRECTED DRAWINGS (as "replacement sheets") must be submitted.
☐ including changes required by the attached Examiner's Amendment / Comment or in the Office action of Paper No./Mail Date _____.

Identifying indicia such as the application number (see 37 CFR 1.84(c)) should be written on the drawings in the front (not the back) of each sheet. Replacement sheet(s) should be labeled as such in the header according to 37 CFR 1.121(d).

6. ☐ DEPOSIT OF and/or INFORMATION about the deposit of BIOLOGICAL MATERIAL must be submitted. Note the attached Examiner's comment regarding REQUIREMENT FOR THE DEPOSIT OF BIOLOGICAL MATERIAL.

Attachment(s)

1. ☐ Notice of References Cited (PTO-892)	5. ☐ Examiner's Amendment/Comment
2. ☐ Information Disclosure Statements (PTO/SB/08), Paper No./Mail Date _____.	6. ☒ Examiner's Statement of Reasons for Allowance
3. ☐ Examiner's Comment Regarding Requirement for Deposit of Biological Material _____.	7. ☐ Other _____.
4. ☐ Interview Summary (PTO-413), Paper No./Mail Date. _____.	

/FRANTZ B JEAN/ Primary Examiner, Art Unit 2454	
--	--

Notice of Pre-AIA or AIA Status

The present application, filed on or after March 16, 2013, is being examined under the first inventor to file provisions of the AIA.

This office action is in response to applicant's arguments filed on 13 November 2023. Claims 1-25 are allowed over the prior art of record.

The following is an examiner's statement of reasons for allowance:

. The prior art of record fails to teach and suggest as a combination a detector for identifying at least one material property m comprising at least one sensor element comprising a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein the sensor element is configured for recording at least one reflection image of a light beam originating from at least one object; and at least one evaluation device configured for determining the material property by evaluation of at least one beam profile of the reflection image, wherein the evaluation device is configured for determining at least one distance feature Φ_{1z} by applying at least one distance dependent image filter D_1 to the reflection image, wherein the distance dependent image filter is at least one filter selected from the group consisting of: a depth-from-photon-ratio filter; a depth-from-defocus filter; or a linear combination thereof; and a further distance dependent image filter Φ_{1other} which correlates to the depth-from-photon-ratio filter and/or the depth-from-defocus filter or a linear combination thereof by $|p_{ot_{her}, o_z}| > 0.40$ with ... being one of the depth-from-photon-ratio filter or the depth-from-defocus filter or a linear combination thereof, wherein the evaluation device is configured for determining at least one material feature ... by applying at least one material dependent image filter O_2 to the reflection image, wherein the material dependent image filter is at least one filter selected from the group consisting of: a luminance filter; a spot shape filter; a squared norm gradient; a standard deviation; a smoothness filter; a Gaussian filter or median filter; a grey-level-occurrence-based contrast filter; a grey-level-occurrence-

Art Unit: 2454

based energy filter; a grey-level-occurrence-based homogeneity filter; a grey-level-occurrence-based dissimilarity filter; a Law's energy filter; a threshold area filter; or a linear combination thereof; and a further material dependent image filter $O_{z_0}th_{er}$ which correlates to one or more of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof by $|po2ot_{er,om}|^{20.40}$ with ... being one of the luminance filter, the spot shape filter, the squared norm gradient, the standard deviation, the smoothness filter, the grey-level-occurrence-based energy filter, the grey-level-occurrence-based homogeneity filter, the grey-level-occurrence-based dissimilarity filter, the Law's energy filter, or the threshold area filter, or a linear combination thereof, and wherein the evaluation device is configured for determining a longitudinal coordinate z and the material property m by evaluating the distance feature ... and the material feature

Any comments considered necessary by applicant must be submitted no later than the payment of the issue fee and, to avoid processing delays, should preferably accompany the issue fee. Such submissions should be clearly labeled "Comments on Statement of Reasons for Allowance."

Any inquiry concerning this communication or earlier communications from the examiner should be directed to FRANTZ B JEAN whose telephone number is (571)272-3937. The examiner can normally be reached 8-5 M-F.

Examiner interviews are available via telephone, in-person, and video conferencing using a USPTO supplied web-based collaboration tool. To schedule an interview, applicant is encouraged to use the USPTO Automated Interview Request (AIR) at <http://www.uspto.gov/interviewpractice>.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Glenton B Burgess can be reached on 5712723949. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.

Information regarding the status of published or unpublished applications may be obtained from Patent Center. Unpublished application information in Patent Center is available to registered users. To file and manage patent submissions in Patent Center, visit: <https://patentcenter.uspto.gov>. Visit <https://www.uspto.gov/patents/apply/patent-center> for more information about Patent Center and <https://www.uspto.gov/patents/docx> for information about filing in DOCX format. For additional questions, contact the Electronic Business Center (EBC) at 866-217-9197 (toll-free). If you would like assistance from a USPTO Customer Service Representative, call 800-786-9199 (IN USA OR CANADA) or 571-272-1000.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as

described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

This Acknowledgement Receipt evidences receipt on the noted date by the USPTO of the indicated documents, characterized by the applicant, and including page counts, where applicable. It serves as evidence of receipt similar to a Post Card, as described in MPEP 503.

New Applications Under 35 U.S.C. 111

If a new application is being filed and the application includes the necessary components for filing date (see 37 CFR 1.53(b)-(d) and MPEP 506), a Filing Receipt (37 CFR 1.54) will be issued in due course and the date shown on this Acknowledgement Receipt will establish the filing date of the application

National Stage of an International Application under 35 U.S.C. 371

If a timely submission to enter the national stage of an international application is compliant with the conditions of 35 U.S.C. 371 and other applicable requirements a Form PCT/DO/EO/903 indicating acceptance of the application as a national stage submission under 35 U.S.C. 371 will be issued in addition to the Filing Receipt, in due course.

New International Application Filed with the USPTO as a Receiving Office

If a new international application is being filed and the international application includes the necessary components for an international filing date (see PCT Article 11 and MPEP 1810), a Notification of the International Application Number and of the International Filing Date (Form PCT/RO/105) will be issued in due course, subject to prescriptions concerning national security, and the date shown on this Acknowledgement Receipt will establish the international filing date of the application.

PART B - FEE(S) TRANSMITTAL

Complete and send this form, together with applicable fee(s), by mail or fax, or via the USPTO patent electronic filing system.

By mail, send to: Mail Stop ISSUE FEE
Commissioner for Patents
P.O. Box 1450
Alexandria, Virginia 22313-1450

By fax, send to: (571)-273-2885

INSTRUCTIONS: This form should be used for transmitting the ISSUE FEE and PUBLICATION FEE (if required). Blocks 1 through 5 should be completed where appropriate. All further correspondence will be mailed to the current correspondence address as indicated unless corrected below or directed otherwise in Block 1, by (a) specifying a new correspondence address; and/or (b) indicating a separate "FEE ADDRESS" for maintenance fee notifications. **Because electronic patent issuance may occur shortly after issue fee payment, any desired continuing application should preferably be filed prior to payment of this issue fee in order not to jeopardize copendency.**

CURRENT CORRESPONDENCE ADDRESS (Note: Use Block 1 for any change of address)

Note: A certificate of mailing can only be used for domestic mailings of the Fee(s) Transmittal. This certificate cannot be used for any other accompanying papers. Each additional paper, such as an assignment or formal drawing, must have its own certificate of mailing or transmission.

Certificate of Mailing or Transmission

I hereby certify that this Fee(s) Transmittal is being deposited with the United States Postal Service with sufficient postage for first class mail in an envelope addressed to the Mail Stop ISSUE FEE address above, or being transmitted to the USPTO via the USPTO patent electronic filing system or by facsimile to (571) 273-2885, on the date below.

JEAN, FRANTZ B	2454	348-135000

1. Change of correspondence address or indication of "Fee Address" (37 CFR 1.363).

☐ Change of correspondence address (or Change of Correspondence Address form PTO/AIA/122 or PTO/SB/122) attached.

☐ "Fee Address" indication (or "Fee Address" Indication form PTO/AIA/47 or PTO/SB/47; Rev 03-02 or more recent) attached. **Use of a Customer Number is required.**

2. For printing on the patent front page, list

(1) The names of up to 3 registered patent attorneys or agents OR, alternatively,

(2) The name of a single firm (having as a member a registered attorney or agent) and the names of up to 2 registered patent attorneys or agents. If no name is listed, no name will be printed.

1 Armstrong Teasdale LLP

2 _____

3 _____

3. ASSIGNEE NAME AND RESIDENCE DATA TO BE PRINTED ON THE PATENT (print or type)

PLEASE NOTE: Unless an assignee is identified below, no assignee data will appear on the patent. If an assignee is identified below, the document must have been previously recorded, or filed for recordation, as set forth in 37 CFR 3.11 and 37 CFR 3.81(a). Completion of this form is NOT a substitute for filing an assignment.

(A) NAME OF ASSIGNEE

(B) RESIDENCE: (CITY and STATE OR COUNTRY)

TRINAMIX GMBH

LUDWIGSHAFEN AM RHEIN, GERMANY

Please check the appropriate assignee category or categories (will not be printed on the patent): ☐ Individual ☒ Corporation or other private group entity ☐ Government

4a. Fees submitted: ☒ Issue Fee ☐ Publication Fee (if required)

4b. Method of Payment: (Please first reapply any previously paid fee shown above)

☒ Electronic Payment via the USPTO patent electronic filing system ☐ Enclosed check ☐ Non-electronic payment by credit card (Attach form PTO-2038)

☒ The Director is hereby authorized to charge the required fee(s), any deficiency, or credit any overpayment to Deposit Account No. 012384

5. Change in Entity Status (from status indicated above)

☐ Applicant certifying micro entity status. See 37 CFR 1.29

☐ Applicant asserting small entity status. See 37 CFR 1.27

☐ Applicant changing to regular undiscounted fee status.

NOTE: Absent a valid certification of Micro Entity Status (see forms PTO/SB/15A and 15B), issue fee payment in the micro entity amount will not be accepted at the risk of application abandonment.

NOTE: If the application was previously under micro entity status, checking this box will be taken to be a notification of loss of entitlement to micro entity status.

NOTE: Checking this box will be taken to be a notification of loss of entitlement to small or micro entity status, as applicable.

NOTE: This form must be signed in accordance with 37 CFR 1.31 and 1.33. See 37 CFR 1.4 for signature requirements and certifications.

ISSUE NOTIFICATION

The projected patent number and issue date are specified above. The patent will issue electronically. The electronically issued patent is the official patent grant pursuant to 35 U.S.C. § 153. The patent may be accessed on or after the issue date through Patent Center at <https://patentcenter.uspto.gov/>. The patent will be available in both the public and the private sides of Patent Center. Further assistance in electronically accessing the patent, or about Patent Center, is available by calling the Patent Electronic Business Center at 1-888-217-9197.

The USPTO is implementing electronic patent issuance with a transition period, during which period the USPTO will mail a ceremonial paper copy of the electronic patent grant to the correspondence address of record. Additional copies of the patent (i.e., certified and presentation copies) may be ordered for a fee from the USPTO's Certified Copy Center at <https://certifiedcopycenter.uspto.gov/index.html>. The Certified Copy Center may be reached at (800)972-6382.

Determination of Patent Term Adjustment under 35 U.S.C. 154 (b) (application filed on or after May 29, 2000)

The Patent Term Adjustment is 314 day(s). Any patent to issue from the above-identified application will include an indication of the adjustment on the front page.

If a Continued Prosecution Application (CPA) was filed in the above-identified application, the filing date that determines Patent Term Adjustment is the filing date of the most recent CPA.

Applicant will be able to obtain more detailed information by accessing the Patent Center (<https://patentcenter.uspto.gov>).

Any questions regarding the Patent Term Extension or Adjustment determination should be directed to the Office of Patent Legal Administration at (571)-272-7702. Questions relating to issue and publication fee payments should be directed to the Application Assistance Unit (AAU) of the Office of Patents Stakeholder Experience (OPSE), Stakeholder Support Division (SSD) at (571)-272-4200.

INVENTOR(s) (Please see PATENT CENTER site <https://patentcenter.uspto.gov> for additional inventors):

Friedrich Schick, Ludwigshafen, GERMANY;
Peter Schillen, Ludwigshafen, GERMANY;
Patrick Schindler, Ludwigshafen, GERMANY;
Andre Schmidt, Ludwigshafen, GERMANY;
Michael Eberspach, Ludwigshafen, GERMANY;

APPLICANT(s) (Please see PATENT CENTER site <https://patentcenter.uspto.gov> for additional applicants):

trinamiX GmbH, Ludwigshafen am Rhein, GERMANY;

The United States represents the largest, most dynamic marketplace in the world and is an unparalleled location for business investment, innovation, and commercialization of new technologies. The USA offers tremendous resources and advantages for those who invest and manufacture goods here. Through SelectUSA, our nation works to encourage and facilitate business investment. To learn more about why the USA is the best country in the world to develop technology, manufacture products, and grow your business, visit [SelectUSA.gov](https://selectusa.gov).
