40 As outlined above, the at least one longitudinal optical sensor may be transparent or intransparent, or may comprise at least one transparent longitudinal optical sensor. A

combination of at least one transparent and at least one intransparent longitudinal optical sensor is possible.

5 In a further preferred embodiment, the last longitudinal optical sensor may be intransparent. For this purpose, at least those parts of the last longitudinal optical sensor which are subject to be illuminated by the light beam which travels from the object and which may impinge on the last longitudinal optical sensor may comprise an optical sensor material, preferably an inorganic optical sensor material, and/or an organic optical sensor material, and/or a hybrid organic – inorganic optical sensor material, which exhibits intransparent optical properties. Intransparency
10 may also be achieved by using at least one intransparent electrode. In this embodiment, the last longitudinal optical sensor may be designed such that its electrode facing towards the object is transparent, whereas its electrode facing away from the object may be intransparent, or vice-versa. Additionally or alternatively, a respective material which exhibits intransparent optical properties may be selected for at least one of the n-semiconducting metal oxides, for at least
15 one of the dyes, and/or for at least one of the p-semiconducting organic materials which may comprise the last longitudinal optical sensor.

As outlined above, the detector may comprise at least one imaging device. The imaging device may fully or partially be embodied as an independent imaging device, independent from the at
20 least one transversal optical sensor and the at least one longitudinal optical sensor. Additionally or alternatively, the at least one optional imaging device may fully or partially be integrated into one or both of the at least one transversal optical sensor and the at least one longitudinal optical sensor. Thus, as an example, the imaging device may be used for determining a transversal position of a light spot and, thus, may be used as a transversal optical sensor or as a part
25 thereof.

As outlined above, the detector may comprise a stack of at least two optical sensors, the at least two optical sensors comprising the at least one transversal optical sensor and the at least one longitudinal optical sensor and, optionally, the at least one imaging device. Thus, as an
30 example, the stack may comprise the at least one transversal optical sensor, the at least one longitudinal optical sensor (preferably at least one transparent longitudinal optical sensor) and, optionally, in a position furthest away from the object, at least one imaging device, preferably at least one intransparent imaging device such as a CCD or CMOS chip.

35 The stack of at least two optical sensors optionally may partially or fully be immersed in an oil, in a liquid and/or in a solid material in order to avoid and/or decrease reflections at interfaces. Hereby, the oil, the liquid, and/or the solid material may preferably be transparent, preferentially to a high degree, at least over a part of the ultraviolet, visible, and/or infrared spectral range. In a preferred embodiment, the solid material may be generated by inserting at least one curable
40 substance into a region between at least two optical sensors and treating the curable substance with a treatment, such as by incident light, particularly with light within the ultraviolet range, and/or by an application of a temperature above or below room temperature, by which treatment

the curable substance might be cured, preferentially by hardening the curable substance into the solid material. Alternatively, at least two different curable substances may be inserted into a region between at least two optical sensors, whereby the two different curable substances are selected in a manner that they begin to set into the solid material with or without the treatment as indicated above. However, further treatments and/or other procedures of providing the transparent solid material may be possible. Thus, at least one of the optical sensors of the stack may fully or partially be immersed in the oil and/or the liquid and/or covered with the solid material.

- 10 Alternatively or additionally, the region between the at least two optical sensors may be partially or fully filled with a substance, such as the oil, the liquid and/or the solid material. Hereby, the substance may preferably exhibit a refractive index with a value which may differ from that of the optical sensors adjoining to the substance on one or both sides of the region. However, inserting the additional substance in the regions may require the optical sensors within the stack to observe a minimum spacing between them.

- 15 In case a stack of at least two optical sensors is used, the last optical sensor of the stack may be transparent or intransparent. Thus, an intransparent inorganic optical sensor may be used in a position furthest away from the object. As an example, the last optical sensor of the stack may be or may comprise the at least one optional imaging device, such as at least one CCD or CMOS chip, preferably a full-color CCD or CMOS chip.

- 20 Thus, the intransparent last optical sensor may be used as an imaging device, wherein the imaging device is impinged by the light beam after the light beam has traveled before through the stack of the transparent optical sensors until it impinges the imaging device. In particular, the imaging device can be completely or partly used as a camera, such as an IR camera, or an RGB camera, as described above. Hereby, the intransparent last optical sensor can be embodied in various ways as imaging device. Thus, the intransparent last optical sensor can be for example part of the detector in a detector housing. Alternatively or additionally, however, the intransparent last optical sensor can also be arranged outside the detector housing, for example as a separate imaging device.

- 25 The stack comprising the at least one transversal optical sensor, the at least one longitudinal optical sensor and the optional at least one imaging device may be designed such that the elements of the stack are arranged along an optical axis of the detector. The last element of the stack may be an intransparent optical sensor, preferably selected from the group consisting of an intransparent transversal optical sensor, an intransparent longitudinal optical sensor and an intransparent imaging device such as an intransparent CCD or CMOS chip.

- 30 In a preferred arrangement, the stack comprising the at least one transversal optical sensor, the at least one longitudinal optical sensor and, optionally, the at least one imaging device may be arranged along a common optical axis of the detector, along which the light beam may travel. In

case the stack contains a plurality of optical sensors, the optical sensors comprising the at least one transversal optical sensor, the at least one longitudinal optical sensor and, optionally, the at least one imaging device, wherein at least one of the optical sensors is a transparent optical sensor and wherein at least one of the optical sensors is an intransparent optical sensor, the transparent optical sensor and the intransparent optical sensor, the latter preferably being positioned furthest away from the object, may be arranged along the optical axis of the detector. However, other arrangements are possible.

In a further preferred embodiment, the intransparent last optical sensor is having at least one matrix of pixels, wherein a 'matrix' generally refers to an arrangement of a plurality of the pixels in space, which may be a linear arrangement or an areal arrangement. Generally, the matrix may, thus, preferably be selected from the group consisting of a one-dimensional matrix and a two-dimensional matrix. As an example, the matrix may comprise 100 to 100 000 000 pixels, preferably 1 000 to 1 000 000 pixels and, more preferably, 10 000 to 500 000 pixels. Most preferably, the matrix is a rectangular matrix having pixels arranged in rows and columns.

As further used herein, a pixel generally refers to a light-sensitive element of an optical sensor, such as a minimum uniform unit of the optical sensor adapted to generate a light signal. As an example, each pixel may have a light-sensitive area of $1\ \mu\text{m}^2$ to $5\ 000\ 000\ \mu\text{m}^2$, preferably $100\ \mu\text{m}^2$ to $4\ 000\ 000\ \mu\text{m}^2$, preferably $1\ 000\ \mu\text{m}^2$ to $1\ 000\ 000\ \mu\text{m}^2$ and more preferably $2\ 500\ \mu\text{m}^2$ to $50\ 000\ \mu\text{m}^2$. Still, other embodiments are feasible. The intransparent last optical sensor may be adapted to generate at least one signal which indicates an intensity of illumination for each of the pixels. Thus, as an example, the intransparent last optical sensor may be adapted to generate at least one electronic signal for each of the pixels, whereby each signal indicates the intensity of illumination for the respective pixel. The signal may be an analogue and/or a digital signal. Further, the detector may comprise one or more signal processing devices, such as one or more filters and/or analogue-digital-converters for processing and/or preprocessing the at least one signal.

The intransparent last optical sensor having a matrix of pixels can be selected from the group consisting of: an inorganic semiconductor sensor device such as a CCD chip and/or a CMOS chip; an organic semiconductor sensor device. In the latter case, as an example, the optical sensor may, for example, comprise at least one organic photovoltaic device having a matrix of pixels. As used herein, an organic photovoltaic device generally refers to a device having at least one organic photosensitive element and/or at least one organic layer. Therein, generally, any type of organic photovoltaic device may be used, such as organic solar cells and/or an arbitrary device having at least one organic photosensitive layer. As an example, an organic solar cell and/or a dye-sensitized organic solar cell may be comprised. Further, a hybrid device may be used, such as inorganic – organic photovoltaic devices.

Further preferred embodiments refer to the evaluation device. Thus, the evaluation device may be designed to generate the at least one item of information on the longitudinal position of the

object from at least one predefined relationship between the geometry of the illumination and a relative positioning of the object with respect to the detector, preferably taking account of a known power of the illumination and optionally taking account of a modulation frequency with which the illumination is modulated.

5

In a further preferred embodiment, the detector furthermore may comprise at least one transfer device, wherein the transfer device is designed to feed light emerging from the object to the transversal optical sensor and the longitudinal optical sensor, preferably subsequently. Details and preferred embodiments will be given below.

10

As outlined above, the light beam propagating from the object of the detector may originate from the object or may originate from any other source. Thus, the object itself may emit the light beam. Additionally or alternatively, the object might be illuminated by using an illumination source generating primary light, wherein the object elastically or inelastically reflects the primary light, thereby generating the light beam propagating to the detector. The illumination source itself may be part of the detector. Thus, the detector may comprise at least one illumination source. The illumination source generally may be selected from: an illumination source, which is at least partly connected to the object and/or is at least partly identical to the object; an illumination source which is designed to at least partly illuminate the object with a primary radiation, preferably primary light, wherein the light beam preferably is generated by a reflection of the primary radiation on the object and/or by light emission by the object itself, stimulated by the primary radiation.

15

20

25

30

As outlined above, the detector preferably has a plurality of longitudinal optical sensors. More preferably, the plurality of longitudinal optical sensors is stacked, such as along the optical axis of the detector. Thus, the longitudinal optical sensors may form a longitudinal optical sensor stack. The longitudinal optical sensor stack preferably may be oriented such that the sensor regions of the longitudinal optical sensors are oriented perpendicular to the optical axis. Thus, as an example, sensor areas or sensor surfaces of the single longitudinal optical sensors may be oriented in parallel, wherein slight angular tolerances might be tolerable, such as angular tolerances of no more than 10° , preferably of no more than 5° .

35

In case stacked longitudinal optical sensors are provided, the at least one transversal optical sensor preferably fully or partially is located on a side of the stacked longitudinal optical sensors facing the object. However, other embodiments are feasible. Thus, embodiments in which the at least one transversal optical sensor is fully or partially located on a side of the transversal optical sensor stack facing away from the object. Again, additionally or alternatively, embodiments are feasible in which the at least one transversal optical sensor is located fully or partially in between the longitudinal optical sensor stack.

40

The longitudinal optical sensors preferably are arranged such that a light beam from the object illuminates all longitudinal optical sensors, preferably sequentially. Specifically in this case,

preferably, at least one longitudinal sensor signal is generated by each longitudinal optical sensor. This embodiment is specifically preferred since the stacked setup of the longitudinal optical sensors allows for an easy and efficient normalization of the signals, even if an overall power or intensity of the light beam is unknown. Thus, the single longitudinal sensor signals may be known to be generated by one and the same light beam. Thus, the evaluation device may be adapted to normalize the longitudinal sensor signals and to generate the information on the longitudinal position of the object independent from an intensity of the light beam. For this purpose, use may be made of the fact that, in case the single longitudinal sensor signals are generated by one and the same light beam, differences in the single longitudinal sensor signals are only due to differences in the cross-sections of the light beam at the location of the respective sensor regions of the single longitudinal optical sensors. Thus, by comparing the single longitudinal sensor signals, information on a beam cross-section may be generated even if the overall power of the light beam is unknown. From the beam cross-section, information regarding the longitudinal position of the object may be gained, specifically by making use of a known relationship between the cross-section of the light beam and the longitudinal position of the object.

Further, the above-mentioned stacking of the longitudinal optical sensors and the generation of a plurality of longitudinal sensor signals by these stacked longitudinal optical sensors may be used by the evaluation device in order to resolve an ambiguity in a known relationship between a beam cross-section of the light beam and the longitudinal position of the object. Thus, even if the beam properties of the light beam propagating from the object to the detector are known fully or partially, it is known that, in many beams, the beam cross-section narrows before reaching a focal point and, afterwards, widens again. Thus, before and often as a focal point in which the light beam has the narrowest beam cross-section, positions along the axis of propagation of the light beam occur in which the light beam has the same cross-section. Thus, as an example, at a distance z_0 before and after the focal point, the cross-section of the light beam is identical. Thus, in case only one longitudinal optical sensor is used, a specific cross-section of the light beam might be determined, in case the overall power or intensity of the light beam is known. By using this information, the distance z_0 of the respective longitudinal optical sensor from the focal point might be determined. However, in order to determine whether the respective longitudinal optical sensor is located before or behind the focal point, additional information is required, such as a history of movement of the object and/or the detector and/or information on whether the detector is located before or behind the focal point. In typical situations, this additional information may not be provided. Therefore, by using a plurality of longitudinal optical sensors, additional information may be gained in order to resolve the above-mentioned ambiguity. Thus, in case the evaluation device, by evaluating the longitudinal sensor signals, recognizes that the beam cross-section of the light beam on a first longitudinal optical sensor is larger than the beam cross-section of the light beam on a second longitudinal optical sensor, wherein the second longitudinal optical sensor is located behind the first longitudinal optical sensor, the evaluation device may determine that the light beam is still narrowing and that the location of the first longitudinal optical sensor is situated before the focal point of the

light beam. Contrarily, in case the beam cross-section of the light beam on the first longitudinal optical sensor is smaller than the beam cross-section of the light beam on the second longitudinal optical sensor, the evaluation device may determine that the light beam is widening and that the location of the second longitudinal optical sensor is situated behind the focal point.

5 Thus, generally, the evaluation device may be adapted to recognize whether the light beam widens or narrows, by comparing the longitudinal sensor signals of different longitudinal sensors.

10 In addition to the at least one longitudinal coordinate of the object, at least one transversal coordinate of the object may be determined. Thus, generally, the evaluation device may further be adapted to determine at least one transversal coordinate of the object by determining a position of the light beam on the at least one transversal optical sensor, which may be a pixelated, a segmented or a large-area transversal optical sensor, as will be outlined in further detail below.

15 Thus, in case a pixelated transversal optical sensor is used and/or in case the at least one transversal optical sensor comprises at least one pixelated optical sensor having a matrix of pixels, the evaluation device may be adapted to determine a center of illumination of the at least one matrix by the light beam, wherein the at least one transversal coordinate of the object is
20 determined by evaluating at least one coordinate of the center of illumination. Thus, the coordinate of the center of illumination may be a pixel coordinate of the center of illumination. As an example, the matrix may comprise rows and columns of pixels, wherein the row number of the light beam and/or the center of the light beam within the matrix may provide an x-coordinate, and wherein the column number of the light beam and/or the center of the light
25 beam within the matrix may provide a y-coordinate.

The detector, as outlined above, may comprise at least one stack of optical sensors, the optical sensors comprising the at least one transversal optical sensor and the at least one longitudinal optical sensor, and, optionally, the at least one imaging device. The stack of optical sensors
30 may comprise at least one longitudinal optical sensor stack, being a stack of longitudinal optical sensors, having at least two longitudinal optical sensors in a stacked fashion. The longitudinal optical sensor stack preferably may comprise at least three longitudinal optical sensors, more preferably at least four longitudinal optical sensors, even more preferably at least five longitudinal optical sensors or even at least six longitudinal optical sensors. By tracking the
35 longitudinal sensor signals of the longitudinal optical sensors, even a beam profile of the light beam might be evaluated.

In case a plurality of the longitudinal optical sensors is used, wherein the plurality of the optical sensors may be arranged in the stacked fashion and/or in another arrangement, the longitudinal
40 optical sensors may have identical spectral sensitivities or may provide different spectral sensitivities. Thus, as an example, at least two of the longitudinal optical sensors may have a differing spectral sensitivity. As used herein, the term spectral sensitivity generally refers to the

fact that the sensor signal of the optical sensor, for the same power of the light beam, may vary with the wavelength of the light beam. Thus, generally, at least two of the optical sensors may differ with regard to their spectral properties. This embodiment generally may be achieved by using different types of absorbing materials for the optical sensors, such as different types of dyes or other absorbing materials.

Preferably, the at least one transversal optical sensor uses at least one transparent substrate. Similarly, preferably, the at least one longitudinal optical sensor uses at least one transparent substrate. In case a plurality of longitudinal optical sensors is used, such as a stack of longitudinal optical sensors, preferably, at least one of these longitudinal optical sensors uses a transparent substrate. Herein, the substrates employed for the plurality of optical sensors may exhibit identical properties or may differ from each other, in particular, with regard to a geometrical quantity and/or a material quantity related to the substrates, such as the thickness, the shape, and/or the refractive index of each substrate. Thus, identical planar glass plates may be used for the plurality of optical sensors within the stack. On the other hand, different substrates may be employed for some optical sensors or for each optical sensor within a plurality of optical sensors, in particular, for a purpose of optimizing the light path within the stack, especially for guiding the light path along regions on the optical axis which might particularly be suited for exploiting the FiP-effect as described elsewhere in this application. Within this regard, the thickness of some substrates or of each substrate, which may be defined by the light path as traversed by the light beam travelling through the respective substrate, may thus be varied, in particular, for reducing or else increasing or even maximizing reflections of the light beam.

In addition or alternatively, the substrates employed for the plurality of optical sensors may differ by exhibiting a different shape which may be selected from the group comprising a planar, a planar-convex, a planar-concave, a biconvex, a biconcave or any other form which may be employed for optical purposes, such as lenses or prisms. Herein, the substrates may be rigid or else flexible. Suitable substrates are, as well as metal foils, in particular plastic sheets or films and especially glass sheets or glass films. Shape-changing materials, such as shape-changing polymers, constitute an example of materials which may preferentially be employed as flexible substrates. Furthermore, the substrate may be covered or coated, in particular, for the purpose of reducing and/or modifying reflections of the incident light beam. As an example, the substrate may be shaped in a manner that it might exhibit a mirror effect, such as that of a dichroic mirror, which might particularly be useful in a setup where a splitting of the optical axis behind the substrate may be required for any purpose.

Additionally or alternatively, differing spectral properties of the optical sensors may be generated by other means implemented into the optical sensors and/or into the detector, such as by using one or more wavelength-selective elements, such as one or more filters (such as color filters) in front of the optical sensors and/or by using one or more prisms and/or by using one or more dichroitic mirrors and/or by using one or more color conversion elements. Thus, in

case a plurality of longitudinal optical sensors is provided, at least one of the longitudinal optical sensors may comprise a wavelength-selective element such as a color filter, having a specific transmission or reflection characteristic, thereby generating differing spectral properties of the optical sensors. Further, the longitudinal optical sensors may all be organic optical sensors, may all be inorganic optical sensors, may all be hybrid organic – inorganic optical sensors or may comprise an arbitrary combination of at least two optical sensors selected from the group consisting of organic optical sensors, inorganic optical sensors and hybrid organic – inorganic optical sensors.

In case the plurality of the longitudinal optical sensors is used, wherein at least two of the longitudinal optical sensors differ with regard to their respective spectral sensitivity, the evaluation device generally may be adapted to determine a color of the light beam by comparing sensor signals of the longitudinal optical sensors having the differing spectral sensitivity. As used herein, the expression “determine a color” generally refers to the step of generating at least one item of spectral information about the light beam. The at least one item of spectral information may be selected from the group consisting of a wavelength, specifically a peak wavelength; color coordinates, such as CIE coordinates. As further used herein, a “color” of the light beam generally refers to a spectral composition of the light beam. Specifically, the color of the light beam may be given in any arbitrary color coordinate system and/or in spectral units such as by giving a wavelength of a dominant peak of a spectrum of the light. Other embodiments are feasible. In case the light beam is a narrow-band light beam such as a laser light beam and/or a light beam generated by a semiconductor device such as a light-emitting diode, the peak wavelength of the light beam may be given to characterize the color of the light beam. The determination of the color of the light beam may be performed in various ways which are generally known to the skilled person. Thus, the spectral sensitivities of the longitudinal optical sensors may span a coordinate system in color space, and the signals provided by the optical sensors may provide a coordinate in this color space, as known to the skilled person for example from the way of determining CIE coordinates. As an example, the detector may comprise two, three or more longitudinal optical sensors in a stack. Thereof, at least two, preferably at least three, of the optical sensors may have differing spectral sensitivities, whereby three different longitudinal optical sensors with maximum absorption wavelengths in a spectral range between 600 nm and 780 nm (red), between 490 nm and 600 nm (green), and between 380 nm and 490 nm (blue) are generally preferred. Further, the evaluation device may be adapted to generate at least one item of color information for the light beam by evaluating the signals of the longitudinal optical sensors having differing spectral sensitivities.

The evaluation device may be adapted to generate at least two color coordinates, preferably at least three color coordinates, wherein each of the color coordinates is determined by dividing a signal of one of the spectrally sensitive optical sensors by a normalization value. As an example, the normalization value may contain a sum of the signals of all spectrally sensitive optical sensors. Additionally or alternatively, the normalization value may contain a detector signal of a white detector. The at least one item of color information may contain the color

coordinates. The at least one item of color information may, as an example, contain CIE coordinates.

Furthermore, in addition to the preferred at least two, more preferably at least three, spectrally sensitive longitudinal optical sensors, wherein at least two of the optical sensors differ with regard to their respective spectral sensitivity, particularly wherein the spectral sensitivities of the at least two longitudinal optical sensors may span a coordinate system in color space, the stack may comprise a last longitudinal optical sensor, wherein the last longitudinal optical sensor may be intransparent. An intransparency of the last longitudinal optical sensor may be achieved by selecting an optically intransparent material from the group consisting of: organic optical sensor materials, inorganic optical sensor materials and hybrid organic – inorganic optical sensor materials.

In a preferred embodiment, the intransparent last longitudinal optical sensor may be configured to exhibit an absorption spectrum which either does not vary at all or varies only to minor extent over the spectral range of the at least two different optical sensors. Whereas each of the at least two different optical sensors displays a specific spectral sensitivity which may, as described above, vary considerably over their spectral range allowing them to be sensitive to a specific color, the intransparent last longitudinal optical sensor may, thus, absorb substantially all colors over the spectral ranges of the at least two of the longitudinal optical sensors have a differing spectral sensitivity. By this property, the last longitudinal optical sensor may be described as a white detector, wherein the white detector may be adapted to absorb light in an absorption range covering the visible spectral range. This arrangement has the advantage that, irrespective of the specific color, each beam which propagates through the at least two different optical sensors until it impinges the intransparent last longitudinal optical sensor, will be recorded by at least two different optical sensors, i.e. by at least one of the at least two different optical sensors which is sensitive to the color as the first longitudinal optical sensor and by the intransparent last longitudinal optical sensor as the second longitudinal optical sensor. As described above, by recording at least one object by both the first longitudinal optical sensor and the second longitudinal optical sensor it will be possible to resolve the ambiguity in the known relationship between the beam cross-section of the light beam and the longitudinal position of the at least one object, wherein the resolving of the ambiguity may work separately for each color which may be recorded. In addition, it may be advantageous to set a first signal recorded by the first longitudinal optical sensor in relationship to a second signal recorded by the last or second longitudinal optical sensor, such as by calculating a quotient or another related relationship. A result obtained by creating such a relationship may particularly facilitate the recognition of a certain color by this arrangement.

As outlined above, the intransparent last longitudinal optical sensor may be a large-area sensor having a single sensitive area or may comprise at least one matrix of pixels, i.e. may be a pixelated optical sensor or imaging sensor. In a further preferred embodiment, the pixels themselves may be equipped with different spectral sensitivity which may allow them to become

sensitive to a specific color. Hereby, the specific colors may be distributed over the area of the last longitudinal optical sensor in any fashion, for example in a random fashion. However, an arrangement is preferred wherein pixels with sensitivity to a specific color are placed in an alternating fashion over the area of the intransparent last longitudinal optical sensor. By way of example, two, three, or four pixels with different sensitivity, e.g. three pixels with a specific sensitivity to red, green, and blue, alternate each other in a one-dimensional or, preferably, in a two-dimensional manner, over the area of the last longitudinal optical sensor. This arrangement may further be interrupted by white pixels, i.e. pixels which exhibit a spectral sensitivity over a large spectral range, e.g. over the visible spectrum, or over a spectrum which may include infrared or ultraviolet shares.

In a further preferred embodiment, the detector may be adapted, such as by using at least one optically sensitive element. As further used herein, the "optically sensitive element" may be considered as an arbitrary optical element which may be sensitive to a specific value of an optical property or to a specific range of values of the optical property of the light beam which may impinge on the optically sensitive element in a manner that the specific value of the optical property or to the specific range of values of the optical property is preferred with regard to other values of the light beam. The optical property as employed here may be selected from the group referring to the light beam and consisting of: a wavelength, a phase, and a polarization. Thus, the optically sensitive element may be designated as a wavelength-sensitive element, a phase-sensitive element, and/or a polarization-sensitive element, respectively. Examples for wavelength-sensitive elements may comprise one or more of a prism, a grating, a dichroitic mirror, a color wheel, or a color drum.

By using the optically sensitive element, the light beam may be influenced by an optical effect related to the at least one optical property immediately before an interaction, during the interaction and/or immediately after the interaction of the light beam with the optically sensitive element. Consequently, an expression like "passing through the optically sensitive element" may refer to a time period during which the light beam may interact with the respective element. In general, the optically sensitive element may induce the optical effect on the light beam impinging on the optically sensitive element, such as by altering a transmission or a reflectance of the impinging light beam.

Within this particular embodiment, for sequentially detecting detector signals for the different optical properties, such as different colors, different phases, and/or different polarizations, the at least one optically sensitive element may be adapted to sequentially influence the light beam. As an example for a sequential process, a rotating filter wheel may be used having filter segments of different transmission properties, for periodically influencing the light beam. Thus, each cycle of rotation of the filter wheel may be split into time segments, wherein each segment may correspond to a different optical property, such as to a different color, a different phase and/or a different polarization. With regard to a filter wheel wherein each segment corresponds to a different polarization, the filter wheel may preferably exhibit an elliptical polarization, in

particular a circular polarization, which may be changing along the circumference of the filter wheel, for example in a discrete or in a continuous manner. However, other embodiments, such as filter wheels which may employ different orientations of a linear polarization within different segments, may be feasible.

5

In general, at least one optical sensor may be placed behind the filter wheel, in order to generate at least one combined detector signal. By evaluating the at least one combined detector signal in a time-resolved fashion, such as by using a phase-sensitive detection, the combined detector signal may be split into partial detector signals corresponding to the different
10 time segments and, thus, corresponding to the different colors of the light beam. Thereby, detector signals for each color, each phase and/or each polarization may be generated, which may correspond to the light beams impinging on the detector. Collecting the data for different optical properties, i.e. different colors or phases or polarizations, from the broadly absorbing stack of optical sensors, may result in acquiring the overall distribution. Consequently, the use
15 of a filter wheel may, therefore, allow determining simultaneously the respective optical property, such as color, phase, or polarization, and intensity and depth by using the detector according to the present invention, thereby avoiding the previous necessity to employ solar cells exhibiting different absorption spectra.

20 Generally, as outlined above, the evaluation device may be adapted to generate the at least one item of information on the longitudinal position of the object by determining a diameter of the light beam from the at least one longitudinal sensor signal. As used herein and as used in the following, the diameter of the light beam or, equivalently, a beam waist of the light beam might be used to characterize the beam cross-section of the light beam at a specific location. As
25 outlined above, a known relationship might be used between the longitudinal position of the object and the beam cross-section in order to determine the longitudinal position of the object by evaluating the at least one longitudinal sensor signal. As an example, as outlined above, a Gaussian relationship might be used, assuming that the light beam propagates at least approximately in a Gaussian Manner. For this purpose, the light beam might be shaped
30 appropriately, such as by using an illumination source generating a light beam having known propagation properties, such as a known Gaussian profile. For this purpose, the illumination source itself may generate the light beam having the known properties, which, for example, is the case for many types of lasers, as the skilled person knows. Additionally or alternatively, the illumination source and/or the detector may have one or more beam-shaping elements, such as
35 one or more lenses and/or one or more diaphragms, in order to provide a light beam having known properties, as the skilled person will recognize. Thus, as an example, one or more transfer elements may be provided, such as one or more transfer elements having known beam-shaping properties. Additionally or alternatively, the illumination source and/or the detector, such as the at least one optional transfer element, may have one or more wavelength-
40 selective elements, such as one or more filters, such as one or more filter elements for filtering out wavelengths outside an excitation maximum of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor.

Thus, generally, the evaluation device may be adapted to compare the beam cross-section and/or the diameter of the light beam with known beam properties of the light beam in order to determine the at least one item of information on the longitudinal position of the object,
5 preferably from a known dependency of a beam diameter of the light beam on at least one propagation coordinate in a direction of propagation of the light beam and/or from a known Gaussian profile of the light beam.

In a specific embodiment, the evaluation device is adapted to determine a number N of pixels of
10 at least one pixelated optical sensor of the detector, such as of the last longitudinal optical sensor, which are illuminated by the light beam, the evaluation device further being adapted to determine at least one longitudinal coordinate of the object by using the number N of pixels which are illuminated by the light beam. Therefore, the evaluation device may be adapted to compare, for each of the pixels, the signal to at least one threshold in order to determine
15 whether the pixel is an illuminated pixel or not. This at least one threshold may be an individual threshold for each of the pixels or may be a threshold which is a uniform threshold for the whole matrix. In case a plurality of optical sensors is provided, at least one threshold may be provided for each of the optical sensors and/or for a group comprising at least two of the optical sensors, wherein, for two optical sensors, their respective thresholds may be identical or different. Thus,
20 for each of the optical sensors, an individual threshold may be provided. The threshold may be predetermined and/or fixed. Alternatively, the at least one threshold may be variable. Thus, the at least one threshold may be determined individually for each measurement or groups of measurements. Thus, at least one algorithm may be provided adapted to determine the threshold.

25 The evaluation device may generally be adapted to determine at least one pixel having the highest illumination out of the pixels by comparing the signals of the pixels. Thus, the detector generally may be adapted to determine one or more pixels and/or an area or region of the matrix having the highest intensity of the illumination by the light beam. As an example, in this
30 way, a center of illumination by the light beam may be determined. The highest illumination and/or the information about the at least one area or region of highest illumination may be used in various ways. Thus, as outlined above, the at least one above-mentioned threshold may be a variable threshold. As an example, the evaluation device may be adapted to choose the above-mentioned at least one threshold as a fraction of the signal of the at least one pixel having the
35 highest illumination. Thus, the evaluation device may be adapted to choose the threshold by multiplying the signal of the at least one pixel having the highest illumination with a factor of $1/e^2$. This option is particularly preferred in case Gaussian propagation properties are assumed for the at least one light beam, since the threshold $1/e^2$ generally determines the borders of a light spot having a beam radius or beam waist generated by a Gaussian light beam on the
40 optical sensor.

A further aspect of the present invention makes use of at least two detectors according to the present invention, wherein each of such detectors may be selected as of at least one detector according to one or more of the embodiments disclosed above or disclosed in further detail below. Thus, for optional embodiments of the method, reference might be made to the
5 respective embodiments of the detector.

In a preferred embodiment, the at least one object might be illuminated by using at least one illumination source which generates primary light, wherein the at least one object elastically or inelastically reflects the primary light, thereby generating a plurality of light beams which
10 propagate to one of the at least two detectors. The at least one illumination source may form or may not form a constituent part of each of the at least two detectors which. Thus, the at least one illumination source may be formed independently of the at least two detectors and may, therefore, particularly be located in at least one position which is separated from the at least two detectors. By way of example, the at least one illumination source itself may be or may
15 comprise an ambient light source and/or may be or may comprise an artificial illumination source. This embodiment is preferably suited for an application in which at least two detectors, preferentially two identical detectors, are employed for acquiring depth information, in particular, for the purpose to providing a measurement volume which extends the inherent measurement volume of a single detector.

The inherent measurement volume of a single detector may, in many cases, be described as an approximate half-cone, wherein a first object which is located within the inherent measurement volume may be detected by the single detector whereas a second object which is located outside the inherent measurement volume can principally not be detected by the single
20 detector. The conical surface of the approximate half-cone can be considered to be formed by a virtual reverse light beam which would be emitted by the at least one optical sensor. The virtual reverse light beam would, thus, emerge from the surface of the at least one optical sensor which, however, does not constitute a point source but rather an extended area. From simple geometrical considerations it can be deduced that no virtual reverse light beam emitted by the
25 at least one optical sensor in this manner will be able to reach all positions in all directions in the volume which surrounds the at least one optical sensor. However, the locations which may be virtually hit by the virtual reverse light beam form an approximate half-cone which can be described as the inherent measurement volume of the single detector.

Therefore, in order to be able to cover a large measurement volume which exceeds the inherent measurement volume of a single detector, at least two detectors may be used, wherein the at least two detectors may be identical or may differ from each other with respect to at least one certain technical property as described elsewhere. In general, the large measurement volume comprises an overlapping volume, which denotes a region in space, which may be coherent or
30 not, wherein double or even multiple detection may occur, i.e. a specific object may be detected by two or more detectors independently, at the same time or at different times. Even in case when two or more detectors, particularly two or more identical detectors, are employed, the
35

double or multiple detection of a specific object does not destroy a reliable acquisition of the depth information about the specific object in the overlapping volume. Since the at least one illumination source may be formed independently of the at least two detectors, typically, no relationship exists between a specific illumination source and a specific detector. Therefore, a reliable acquisition of the depth information will also be possible when at least two of the detectors point towards each other. As a result of this disconnection between the specific illumination source and the specific detector, the recording of the depth information about the specific object will not be impaired when the specific object may be located in the overlapping volume. On the contrary, the depth information in the overlapping volume which concerns a specific object may independently been acquired by more than one detector at the same time and can, thus, be used to improve the accuracy of the depth measurement for the specific object. By way of example, this improvement may be achieved by comparing respective depth values which are recorded simultaneously or successively for the same object by at least two separate single detectors.

In a further aspect of the present invention, a human-machine interface for exchanging at least one item of information between a user and a machine is proposed. The human-machine interface as proposed may make use of the fact that the above-mentioned detector in one or more of the embodiments mentioned above or as mentioned in further detail below may be used by one or more users for providing information and/or commands to a machine. Thus, preferably, the human-machine interface may be used for inputting control commands.

The human-machine interface comprises at least one detector according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments as disclosed in further detail below, wherein the human-machine interface is designed to generate at least one item of geometrical information of the user by means of the detector wherein the human-machine interface is designed to assign to the geometrical information at least one item of information, in particular at least one control command.

Generally, as used herein, the at least one item of geometrical information of the user may imply one or more items of information on a transversal position and/or on a longitudinal position of the user and/or one or more body parts of the user. Thus, preferably, the geometrical information of the user may imply one or more items of information on a transversal position and/or a longitudinal position as provided by the evaluation device of the detector. The user, a body part of the user or a plurality of body parts of the user may be regarded as one or more objects which may be detected by the at least one detector. Therein, precisely one detector may be provided, or a combination of a plurality of detectors may be provided. As an example, a plurality of detectors may be provided for determining positions of a plurality of body parts of the user and/or for determining an orientation of at least one body part of the user. The human-machine interface may comprise one or more detectors, wherein, in case a plurality of detectors is provided, the detectors may be identical or may differ. Herein, in case a plurality of detectors

is used, the plurality of detectors, particularly the plurality of identical detectors, still allows for a reliable acquisition of depth information about the at least one object in an overlapping volume which may be recorded, as described above, by the plurality of detectors.

- 5 Thus, preferably, the at least one item of geometrical information of the user is selected from the group consisting of: a position of a body of the user; a position of at least one body part of the user; an orientation of a body of the user; an orientation of at least one body part of the user.
- 10 The human-machine interface may further comprise at least one beacon device connectable to the user. As used herein, a beacon device generally is an arbitrary device which may be detected by the at least one detector and/or which facilitates detection by the at least one detector. Thus, as will be outlined in further detail below, the beacon device may be an active beacon device adapted for generating the at least one light beam to be detected by the
- 15 detector, such as by having one or more illumination sources for generating the at least one light beam. Additionally or alternatively, the beacon device may fully or partially be designed as a passive beacon device, such as by providing one or more reflective elements adapted to reflect a light beam generated by a separate illumination source. The at least one beacon device may permanently or temporarily be attached to the user. The attachment may take place
- 20 by using one or more attachment means and/or by the user himself or herself, such as by the user holding the at least one beacon device by hand and/or by the user wearing the beacon device.

The human-machine interface may be adapted such that the detector may generate an

25 information on the position of the at least one beacon device. Specifically in case a manner of attachment of the at least one beacon device to the user is known, from the at least one item of information on the position of the at least one beacon device at least one item of information regarding a position and/or an orientation of the user or one or more body parts of the user may be gained.

30 The beacon device preferably is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user. As outlined above, the beacon device may fully or partially be designed as an active beacon device. Thus, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be

35 transmitted to the detector, preferably at least one light beam having known beam properties. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

40 The beacon device preferably may comprise at least one of: a garment to be worn by the user, preferably a garment selected from the group consisting of a glove, a jacket, a hat, shoes,

trousers and a suit; a stick that may be held by hand; a bat; a club; a racket; a cane; a toy, such as a toy gun.

In a further aspect of the present invention, an entertainment device for carrying out at least one entertainment function is disclosed. As used herein, an entertainment device is a device which may serve the purpose of leisure and/or entertainment of one or more users, in the following also referred to as one or more players. As an example, the entertainment device may serve the purpose of gaming, preferably computer gaming. Additionally or alternatively, the entertainment device may also be used for other purposes, such as for exercising, sports, physical therapy or motion tracking in general. Thus, the entertainment device may be implemented into a computer, a computer network or a computer system or may comprise a computer, a computer network or a computer system which runs one or more gaming software programs.

The entertainment device comprises at least one human-machine interface according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed below. The entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface. The at least one item of information may be transmitted to and/or may be used by a controller and/or a computer of the entertainment device.

The at least one item of information preferably may comprise at least one command adapted for influencing the course of a game. Thus, as an example, the at least one item of information may include at least one item of information on at least one of a movement, the orientation and a position of the player and/or of one or more body parts of the player, thereby allowing for the player to simulate a specific position and/or action required for gaming. As an example, one or more of the following movements may be simulated and communicated to a controller and/or a computer of the entertainment device: dancing; running; jumping; swinging of a racket; swinging of a bat; swinging of a club; pointing of an object towards another object, such as pointing of a toy gun towards a target.

The entertainment device, preferably a controller and/or a computer of the entertainment device, is designed to vary the entertainment function in accordance with the information. Thus, as outlined above, a course of a game might be influenced in accordance with the at least one item of information. Thus, the entertainment device might include one or more controllers which might be separate from the evaluation device of the at least one detector and/or which might be fully or partially identical to the at least one evaluation device or which might even include the at least one evaluation device. Preferably, the at least one controller might include one or more data processing devices, such as one or more computers and/or microcontrollers.

In a further embodiment of the present invention, the entertainment device may be part of an equipment, the equipment being a mobile piece or, in particular, an immobile piece, wherein the equipment may at least partially incorporate the entertainment device. The equipment may

include a single, separate piece being located at a position, either a fixed position or a position at least intermittently subject to a variation, but the equipment may also comprise at least two pieces, preferably two to ten pieces, such as three, four, five, or six pieces, wherein the at least two pieces may be distributed over at least two positions differing from each other within an area, such as a room or a part thereof. Hereby, the entertainment device may be part of the equipment, wherein preferably some or each piece of the equipment may exhibit a part of the entertainment device, e.g. in such a manner that some or each piece of the equipment may comprise at least one detector according to the present invention or a part thereof, such as a sensor. As used herein, "immobile equipment" may include an immobile electronic article, in particular, designated as consumer electronics, wherein "consumer electronics" comprises electronic articles preferentially intended for everyday use, mainly in entertainment, communications and office matters, such as radio receivers, monitors, television sets, audio players, video players, personal computers and/or telephones. A particular example constituting the immobile equipment may be a surround system, which may for example be formed by a number of two, three, four, five, six or more separate pieces of the equipment, such as individual monitors or audio players, including loudspeakers, which may be distributed over an area, preferentially in a specific fashion, such as forming an arc-shaped assembly enclosing a room or a part thereof.

Additionally or alternatively, the entertainment device or a part thereof, such as one, some or each piece of the equipment, may further be equipped with one or more of the following devices: a photographic device, such as a camera, particularly a 2D camera, a picture analysis software, particularly a 2D picture analysis software, and a reference object, particularly a geometrically symmetric reference object, such as a book or a specially formed toy. Hereby, the reference object may also be a part of the immobile equipment and fulfill a further function of the entertainment device as described above and/or below, wherein the reference object may further comprise a detector, a 2D camera or another photographic device. Preferably, a constructive interaction of the photographic device, the picture analysis software and the particularly symmetric reference object, may facilitate an alignment of a 2D picture of an object in question as recorded by the photographic device with the 3D position of the same object as determined by the at least one detector.

In a further embodiment of the present invention, the object which may constitute a target of the at least one detector comprised within the at least one human-machine interface of the entertainment device, may be part of a controller as comprised within mobile equipment, wherein the mobile equipment may be configured to control another mobile equipment or immobile equipment. As used herein, "mobile equipment" may, thus, include mobile electronic articles, in particular, designated as consumer electronics, such as mobile phones, radio receivers, video recorders, audio players, digital cameras, camcorders, mobile computers, video game consoles and/or other devices adapted for remote control. This embodiment may particularly allow controlling immobile equipment with any kind of mobile equipment, preferably with a lesser number of pieces of equipment. As a non-limiting example, it may, thus, be

possible to simultaneously control for example both a game console and a television set by using a mobile phone.

5 Additionally or alternatively, the object which may constitute the target of the detector may further be equipped with an additional sensor (apart from the sensors as comprised within the detector) particularly configured for determining a physical and/or chemical quantity related to the object, such as an inertia sensor for measuring the inertial motion of the object, or an acceleration sensor for determining the acceleration of the object. However, besides these preferred examples, other kinds of sensors adapted for acquiring further parameter related to
10 the object, such as a vibrational sensor for determining vibrations of the object, a temperature sensor for recording the temperature of the object, or a humidity sensor for recording the humidity of the object may be employed. An application of the additional sensor within the object may allow improving the quality and/or the scope of the detection of the position of the object. As a non-limiting example, the additional inertia sensor and/or acceleration sensor may
15 particularly be configured to record additional movements of the object, such as a rotation of the object, which may particularly be employed for increasing the accuracy of the object detection. Moreover, the additional inertia sensor and/or acceleration sensor may preferentially still be addressed in a case where the object being equipped with at least one of these sensors may leave a visual range of the detector comprised within the human-machine interface of the
20 entertainment device. In this case, it might, nevertheless, be possible to follow the object after the object may have left the visual range of the detector by still being able to recording signals emitted from at least one of these sensors and using these signals for determining the location of the object by taking into account its actual inertia and acceleration values and calculating the position therefrom.

25 Additionally or alternatively, the object which may constitute the target of the detector may further be equipped with a further feature allowing both to simulate and/or to stimulate motions, for example by simulating motions of the object, wherein the object may be virtual or real and wherein the object may be controlled by a controller, and/or by stimulating motions of the object
30 by applying the controller accordingly. This feature may particularly be employed for providing a more realistic entertainment experience for a user. As an illustrating example, a steering wheel as employed in an entertainment device may vibrate, wherein the amplitude of the vibrations may depend on a nature of a ground on which a virtual car may be driving on. As a further embodiment, the motion of the object may be stimulated by employing a gyroscope, which may
35 be used for example for a stabilization of flying vehicles as described under the address en.wikipedia.org/wiki/gyroscope.

In a further embodiment of the present invention, the object which may constitute the target of the at least one detector may be equipped with at least one modulation device for modulating
40 the illumination, in particular for a periodic modulation. Preferably, the object may comprise at least one illumination source, which may be part of the object or, alternatively or additionally, be held by the object or attached thereto and which may act as a beacon in a manner as described

elsewhere in this application. The illumination may be adapted to generate at least one light beam to be transmitted to the detector, whereby the illumination source comprises a modulation device for modulating the illumination and/or the modulation device may be a separate device configured for controlling the emission of the illumination source. According to this embodiment, apart from the fundamental modulation of the illumination source, the modulation device may generate additional modulation frequencies, also be denoted as “overtones”, which might be used for transmitting any item of additional information or data from the object to the detector. This embodiment, which might also be designated as a “modulating retro-reflector”, may open the way to employ the object equipped with the modulation device configured for generating both the fundamental and the additional modulation frequencies as remote control. Further, an already existing remote control may be replaced by the object equipped with the described modulation device. Against this background, this kind of object and a piece configured for remote control may interchangeably be used within an arrangement incorporating a detector according to the present invention.

In a further embodiment of the present invention, the entertainment device may further be equipped with additional items such as items commonly used within such an environment. Glasses or other devices being configured for creating a 3D vision within the mind of a player may constitute a particular example.

In a further embodiment of the present invention, the entertainment device may further be equipped with an augmented reality application. As further used herein, “augmented reality” may describe a live perception of reality comprising elements which may be modified by computer-generated data primarily related to physical phenomena such as sound, images, or others. An example may be vision glasses which are particularly adapted for augmented reality applications. Another example may include an arrangement comprising at least two detectors, preferably a multitude thereof, wherein the detectors may particularly be arranged to cover an area within a room or a preferably large part thereof, a photographic device, such as a camera, particularly a 2D camera, and an augmented reality application, wherein the arrangement might be employed to transform a real area into a playing field, which may also be designated as an entertainment field.

In a further aspect of the present invention, a tracking system for tracking the position of at least one movable object is provided. As used herein, a tracking system is a device which is adapted to gather information on a series of past positions of the at least one object or at least one part of an object. Additionally, the tracking system may be adapted to provide information on at least one predicted future position of the at least one object or the at least one part of the object. The tracking system may have at least one track controller, which may fully or partially be embodied as an electronic device, preferably as at least one data processing device, more preferably as at least one computer or microcontroller. Again, the at least one track controller may comprise the at least one evaluation device and/or may be part of the at least one evaluation device and/or may fully or partially be identical to the at least one evaluation device.

The tracking system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The tracking system further comprises at least one track controller. The tracking system may comprise one, two or more detectors, particularly two or more identical detectors, which allow for a reliable acquisition of depth information about the at least one object in an overlapping volume between the two or more detectors. The track controller is adapted to track a series of positions of the object, each position comprising at least one item of information on a transversal position of the object at a specific point in time and at least one item of information on a longitudinal position of the object at a specific point in time.

The tracking system may further comprise at least one beacon device connectable to the object. For a potential definition of the beacon device, reference may be made to the disclosure above. The tracking system preferably is adapted such that the detector may generate an information on the position of the object of the at least one beacon device. For potential embodiments of the beacon device, reference may be made to the disclosure above. Thus, again, the beacon device may fully or partially be embodied as an active beacon device and/or as a passive beacon device. As an example, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be transmitted to the detector. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

The tracking system may be adapted to initiate one or more actions of the tracking system itself and/or of one or more separate devices. For the latter purpose, the tracking system, preferably the track controller, may have one or more wireless and/or wire-bound interfaces and/or other types of control connections for initiating at least one action. Preferably, the at least one track controller may be adapted to initiate at least one action in accordance with at least one actual position of the object. As an example, the action may be selected from the group consisting of: a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.

As an example of application of a tracking system, the tracking system may be used for continuously pointing at least one first object to at least one second object even though the first object and/or the second object might move. Potential examples, again, may be found in industrial applications, such as in robotics and/or for continuously working on an article even though the article is moving, such as during manufacturing in a manufacturing line or assembly line. Additionally or alternatively, the tracking system might be used for illumination purposes, such as for continuously illuminating the object by continuously pointing an illumination source to the object even though the object might be moving. Further applications might be found in

communication systems, such as in order to continuously transmit information to a moving object by pointing a transmitter towards the moving object.

In a further aspect of the present invention, a camera for imaging at least one object is disclosed. The camera comprises at least one detector according to the present invention, such as disclosed in one or more of the embodiments given above or given in further detail below.

Thus, specifically, the present application may be applied in the field of photography. Thus, the detector may be part of a photographic device, specifically of a digital camera. Specifically, the detector may be used for 3D photography, specifically for digital 3D photography. Thus, the detector may form a digital 3D camera or may be part of a digital 3D camera. As used herein, the term "photography" generally refers to the technology of acquiring image information of at least one object. As further used herein, a "camera" generally is a device adapted for performing photography. As further used herein, the term "digital photography" generally refers to the technology of acquiring image information of at least one object by using a plurality of light-sensitive elements adapted to generate electrical signals indicating an intensity and/or color of illumination, preferably digital electrical signals. As further used herein, the term "3D photography" generally refers to the technology of acquiring image information of at least one object in three spatial dimensions. Accordingly, a 3D camera is a device adapted for performing 3D photography. The camera generally may be adapted for acquiring a single image, such as a single 3D image, or may be adapted for acquiring a plurality of images, such as a sequence of images. Thus, the camera may also be a video camera adapted for video applications, such as for acquiring digital video sequences.

Thus, generally, the present invention further refers to a camera, specifically a digital camera, more specifically a 3D camera or digital 3D camera, for imaging at least one object. As outlined above, the term imaging, as used herein, generally refers to acquiring image information of at least one object. The camera comprises at least one detector according to the present invention. The camera, as outlined above, may be adapted for acquiring a single image or for acquiring a plurality of images, such as image sequence, preferably for acquiring digital video sequences. Thus, as an example, the camera may be or may comprise a video camera. In the latter case, the camera preferably comprises a data memory for storing the image sequence.

As used within the present invention, the expression "position" generally refers to at least one item of information regarding one or more of an absolute position and an orientation of one or more points of the object. Thus, specifically, the position may be determined in a coordinate system of the detector, such as in a Cartesian coordinate system. Additionally or alternatively, however, other types of coordinate systems may be used, such as polar coordinate systems and/or spherical coordinate systems.

In a further aspect of the present invention, a method for determining a position of at least one object is disclosed. The method preferably may make use of at least one detector according to

the present invention, such as of at least one detector according to one or more of the embodiments disclosed above or disclosed in further detail below. Thus, for optional embodiments of the method, reference might be made to the embodiments of the detector.

- 5 The method comprises the following steps, which may be performed in the given order or in a different order. Further, additional method steps might be provided which are not listed. Further, two or more or even all of the method steps might be performed at least partially simultaneously. Further, two or more or even all of the method steps might be performed twice or even more than twice, repeatedly.

10

In a first method step, which might also be referred to as a step of determining at least one transversal position, at least one transversal optical sensor is used. The transversal optical sensor determines a transversal position of at least one light beam traveling from the object to the detector, wherein the transversal position is a position in at least one dimension
15 perpendicular to an optical axis of the detector. The transversal optical sensor generates at least one transversal sensor signal.

20

In a further method step, which might also be referred to as a step of determining at least one longitudinal position, at least one longitudinal optical sensor is used. The longitudinal optical sensor has at least one sensor region. The longitudinal optical sensor generates at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region by the light beam. The longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam in the sensor region.

25

In a further method step, which might also be referred to as an evaluation step, at least one evaluation device is used. The evaluation device generates at least one item of information on a transversal position of the object by evaluating the transversal sensor signal and wherein the evaluation device further generates at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal.

30

In a further aspect of the present invention, a use of a detector according to the present invention is disclosed. Therein, a use of the detector for a purpose of use is proposed, selected from the group consisting of: a distance measurement, in particular in traffic technology; a position measurement, in particular in traffic technology; an entertainment application; a security
35 application; a human-machine interface application; a tracking application; a photography application; an imaging application or camera application; a mapping application for generating maps of at least one space.

40

In the following, some additional remarks regarding potential embodiments of the detector, the human-machine interface, the tracking system and the method according to the present invention are given. As outlined above, preferably, for potential details of the setups of the at least one transversal optical detector and the at least one longitudinal optical detector,

reference may be made to WO 2012/110924 A1, specifically with regard to potential electrode materials, organic materials, inorganic materials, layer setups and further details.

The object can generally be a living or else inanimate object. Examples of objects which can be detected completely or partly by means of the detector are described in even greater detail below.

Further, with regard to potential embodiments of the optional transfer device, reference may be made to WO 2012/110924 A1. Thus, this optional transfer device can comprise for example at least one beam path. The transfer device can for example comprise one or a plurality of mirrors and/or beam splitters and/or beam deflecting elements in order to influence a direction of the electromagnetic radiation. Alternatively or additionally, the transfer device can comprise one or a plurality of imaging elements which can have the effect of a converging lens and/or a diverging lens. By way of example, the optional transfer device can have one or a plurality of lenses and/or one or a plurality of convex and/or concave mirrors. Once again alternatively or additionally, the transfer device can have at least one wavelength-selective element, for example at least one optical filter. Once again alternatively or additionally, the transfer device can be designed to impress a predefined beam profile on the electromagnetic radiation, for example, at the location of the sensor region and in particular the sensor area. The abovementioned optional embodiments of the optional transfer device can, in principle, be realized individually or in any desired combination.

Further, generally, it shall be noted that, in the context of the present invention, an optical sensor may refer to an arbitrary element which is designed to convert at least one optical signal into a different signal form, preferably into at least one electrical signal, for example a voltage signal and/or a current signal. In particular the optical sensor can comprise at least one optical-electrical converter element, preferably at least one photodiode and/or at least one solar cell. As is explained in even greater detail below, in the context of the present invention, preference is attached particularly to a use of at least one organic optical sensor, that is to say an optical sensor which comprises at least one organic material, for example at least one organic semiconductor material.

In the context of the present invention, a sensor region should be understood to mean a two-dimensional or three-dimensional region which preferably, but not necessarily, is continuous and can form a continuous region, wherein the sensor region is designed to vary at least one measurable property, in a manner dependent on the illumination. By way of example, said at least one property can comprise an electrical property, for example, by the sensor region being designed to generate, solely or in interaction with other elements of the optical sensor, a photo voltage and/or a photocurrent and/or some other type of signal. In particular, the sensor region can be embodied in such a way that it generates a uniform, preferably a single, signal in a manner dependent on the illumination of the sensor region. The sensor region can thus be the smallest unit of the optical sensor for which a uniform signal, for example, an electrical signal, is

generated, which preferably can no longer be subdivided to partial signals, for example for partial regions of the sensor region. The transversal optical sensor and/or the longitudinal optical sensor each can have one or else a plurality of such sensor regions, the latter case for example by a plurality of such sensor regions being arranged in a two-dimensional and/or three-dimensional matrix arrangement.

The at least one sensor region can comprise for example at least one sensor area, that is to say a sensor region whose lateral extent considerably exceeds the thickness of the sensor region, for example by at least a factor of 10, preferably by at least a factor of 100 and particularly preferably by at least a factor of 1000. Examples of such sensor areas can be found in organic or inorganic photovoltaic elements, for example, in accordance with the prior art described above, or else in accordance with the exemplary embodiments described in even greater detail below. The detector can have one or a plurality of such optical sensors and/or sensor regions. By way of example, a plurality of optical sensors can be arranged linearly in a spaced-apart manner or in a two-dimensional arrangement or else in a three-dimensional arrangement, for example by a stack of photovoltaic elements being used, preferably organic photovoltaic elements, preferably a stack in which the sensor areas of the photovoltaic elements are arranged parallel to one another. Other embodiments are also possible.

The optional transfer device can, as explained above, be designed to feed light propagating from the object to the detector to the transversal optical sensor and/or the longitudinal optical sensor, preferably successively. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the transversal and/or longitudinal optical sensor. The optional transfer device can also, as explained in even greater detail below, be wholly or partly a constituent part of at least one optional illumination source, for example by the illumination source being designed to provide a light beam having defined optical properties, for example having a defined or precisely known beam profile, for example at least one Gaussian beam, in particular at least one laser beam having a known beam profile.

For potential embodiments of the optional illumination source, reference may be made to WO 2012/110924 A1. Still, other embodiments are feasible. Light emerging from the object can originate in the object itself, but can also optionally have a different origin and propagate from this origin to the object and subsequently toward the transversal and/or longitudinal optical sensor. The latter case can be effected for example by at least one illumination source being used. This illumination source can for example be or comprise an ambient light source and/or may be or may comprise an artificial illumination source. By way of example, the detector itself can comprise at least one illumination source, for example at least one laser and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. On account of their generally defined beam profiles and other properties of handleability, the use of one or a

plurality of lasers as illumination source or as part thereof, is particularly preferred. The illumination source itself can be a constituent part of the detector or else be formed independently of the detector. The illumination source can be integrated in particular into the detector, for example a housing of the detector. Alternatively or additionally, at least one
5 illumination source can also be integrated into the object or connected or spatially coupled to the object.

The light emerging from the object can accordingly, alternatively or additionally from the option that said light originates in the object itself emerge from the illumination source and/or be
10 excited by the illumination source. By way of example, the electromagnetic light emerging from the object can be emitted by the object itself and/or be reflected by the object and/or be scattered by the object before it is fed to the optical sensor. In this case, emission and/or scattering of the electromagnetic radiation can be effected without spectral influencing of the electromagnetic radiation or with such influencing. Thus, by way of example, a wavelength shift
15 can also occur during scattering, for example according to Stokes or Raman. Furthermore, emission of light can be excited, for example, by a primary light source, for example by the object or a partial region of the object being excited to effect luminescence, in particular phosphorescence and/or fluorescence. Other emission processes are also possible, in principle. If a reflection occurs, then the object can have for example at least one reflective region, in
20 particular at least one reflective surface. Said reflective surface can be a part of the object itself, but can also be for example a reflector which is connected or spatially coupled to the object, for example a reflector plaque connected to the object. If at least one reflector is used, then it can in turn also be regarded as part of the detector which is connected to the object, for example, independently of other constituent parts of the detector.

25 The at least one illumination source of the detector can generally be adapted to the emission and/or reflective properties of the object, for example in terms of its wavelength. Various embodiments are possible.

30 The at least one optional illumination source generally may emit light in at least one of: the ultraviolet spectral range, preferably in the range of 200 nm to 380 nm; the visible spectral range (380 nm to 780 nm); the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers. Most preferably, the at least one illumination source is adapted to emit light in the visible spectral range, preferably in the range of 500 nm to 780 nm, most preferably at 650 nm
35 to 750 nm or at 690 nm to 700 nm.

The feeding of the light to the transversal and/or longitudinal optical sensor can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is produced on the optional sensor area of the transversal and/or
40 longitudinal optical sensor. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects can be detected. Preferably, the optional transfer device is designed in such a way that the light spot, for example

in the case of an object arranged within a visual range of the detector, is arranged completely on the sensor region, in particular the sensor area. By way of example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

5 The at least one longitudinal optical sensor, as outlined above, can be designed for example in such a way that the longitudinal sensor signal, given the same power of the illumination, that is to say for example given the same integral over the intensity of the illumination on the sensor area, is dependent on the geometry of the illumination, that is to say for example on the diameter and/or the equivalent diameter for the sensor spot. By way of example, the longitudinal
10 optical sensor can be designed in such a way that upon a doubling of the beam cross section given the same total power, a signal variation occurs by at least a factor of 3, preferably by at least a factor of 4, in particular a factor of 5 or even a factor of 10. This condition can hold true for example for a specific focusing range, for example for at least one specific beam cross section. Thus, by way of example, the longitudinal sensor signal can have, between at least one
15 optimum focusing at which the signal can have for example at least one global or local maximum and a focusing outside said at least one optimum focusing, a signal difference by at least a factor of 3, preferably by at least a factor of 4, in particular a factor of 5 or even a factor of 10. In particular, the longitudinal sensor signal can have as a function of the geometry of the illumination, for example of the diameter or equivalent diameter of a light spot, at least one
20 pronounced maximum, for example with a boost by at least a factor of 3, particularly preferably by at least a factor of 4 and particularly preferably by at least a factor of 10. Consequently, the longitudinal optical sensor may be based on the above-mentioned FiP-effect, which is disclosed in great detail in WO 2012/110924 A1. Thus, specifically in sDSCs, the focusing of the light beam may play a decisive role, i.e. the cross-section or cross-sectional area on which a certain
25 number of auf photons (nph) is incident. The more tightly the light beam is focused, i.e. the smaller its cross-section, the higher the photo current may be. The term 'FiP' expresses the relationship between the cross-section ϕ (Fi) of the incident beam and the solar cell's power (P).

30 The at least one longitudinal optical sensor is combined with at least one transversal optical sensor in order to preferably provide appropriate position information of the object.

Such effects of the dependence of the at least one longitudinal sensor signal on a beam geometry, preferably a beam cross-section of the at least one light beam, were observed in the context of the investigations leading to the present invention in particular in the case of organic
35 photovoltaic components, that is to say photovoltaic components, for example, solar cells, which comprise at least one organic material, for example at least one organic p-semiconducting material and/or at least one organic dye. By way of example, such effects, as is explained in even greater detail below by way of example, were observed in the case of dye solar cells, that is to say components which have at least one first electrode, at least one n-semiconducting
40 metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid organic p-type semiconductor, and at least one second electrode. Such dye solar cells, preferably solid dye solar cells (solid dye sensitized solar cells, sDSC), are known in principle in

numerous variations from the literature. The described effect of the dependence of the sensor signal on a geometry of the illumination on the sensor area and a use of this effect have not, however, been described heretofore.

- 5 In particular, the at least one longitudinal optical sensor can be designed in such a way that the sensor signal, given the same total power of the illumination, is substantially independent of a size of the sensor region, in particular of a size of the sensor area, in particular as long as the light spot of the illumination lies completely within the sensor region, in particular the sensor area. Consequently, the longitudinal sensor signal can be dependent exclusively on a focusing
10 of the electromagnetic rays on the sensor area. In particular the sensor signal can be embodied in such a way that a photocurrent and/or a photo voltage per sensor area have/has the same values given the same illumination, for example the same values given the same size of the light spot.
- 15 The evaluation device can comprise in particular at least one data processing device, in particular an electronic data processing device, which can be designed to generate the at least one item of information on the transversal position of the object by evaluating the at least one transversal sensor signal and to generate the at least one item of information on the longitudinal position of the object by evaluating the at least one longitudinal sensor signal. Thus, the
20 evaluation device is designed to use the at least one transversal sensor signal and the at least one longitudinal sensor signal as input variables and to generate the items of information on the transversal position and the longitudinal position of the object by processing these input variables. The processing can be done in parallel, subsequently or even in a combined manner. The evaluation device may use an arbitrary process for generating these items of information,
25 such as by calculation and/or using at least one stored and/or known relationship. Besides the at least one transversal sensor signal and at least one longitudinal sensor signal, one or a plurality of further parameters and/or items of information can influence said relationship, for example at least one item of information about a modulation frequency. The relationship can be determined or determinable empirically, analytically or else semi-empirically. Particularly
30 preferably, the relationship comprises at least one calibration curve, at least one set of calibration curves, at least one function or a combination of the possibilities mentioned. One or a plurality of calibration curves can be stored for example in the form of a set of values and the associated function values thereof, for example in a data storage device and/or a table. Alternatively or additionally, however, the at least one calibration curve can also be stored for
35 example in parameterized form and/or as a functional equation. Separate relationships for processing the at least one transversal sensor signal into the at least one item of information on the transversal position and for processing the at least one longitudinal sensor signal into the at least one item of information on the longitudinal position may be used. Alternatively, at least one combined relationship for processing the sensor signals is feasible. Various possibilities are
40 conceivable and can also be combined.

By way of example, the evaluation device can be designed in terms of programming for the purpose of determining the items of information. The evaluation device can comprise in particular at least one computer, for example at least one microcomputer. Furthermore, the evaluation device can comprise one or a plurality of volatile or nonvolatile data memories. As an
5 alternative or in addition to a data processing device, in particular at least one computer, the evaluation device can comprise one or a plurality of further electronic components which are designed for determining the items of information, for example an electronic table and in particular at least one look-up table and/or at least one application-specific integrated circuit (ASIC).

10 The combination of the at least one item of information on the transversal position and the at least one item of information on the longitudinal position allows for a multiplicity of possible uses of the detector, which will be described by way of example hereinafter. As outlined in great detail in WO 2012/110924 A1, a cross-section of the light beam, resulting in a specific diameter
15 or equivalent diameter of a light spot on the sensor region of the at least one longitudinal optical sensor, can be dependent on a distance between the object and the detector and/or on the optional transfer device of the detector, for example at least one detector lens. By way of example, a variation of the distance between the object and a lens of the optional transfer device can lead to a defocusing of the illumination on the sensor region, accompanied by a
20 change in the geometry of the illumination, for example a widening of a light spot, which can result in a correspondingly altered longitudinal sensor signal or a multiplicity of altered longitudinal sensor signals, in case a plurality of longitudinal optical sensors is used. Even without a transfer device, by way of example, from a known beam profile from the sensor signal and/or a variation thereof, for example, by means of a known beam profile and/or a known
25 propagation of the light beam, it is possible to deduce a defocusing and/or the geometrical information. By way of example, given a known total power of the illumination, it is thus possible to deduce from the longitudinal sensor signal of the longitudinal optical sensor a geometry of the illumination and therefrom in turn the geometrical information, in particular at least one item of location information of the object.

30 Similarly, the at least one transversal optical sensor allows for an easy detection of a transversal position of the object. For this purpose, use may be made of the fact that a change in a transversal position of the object generally will lead to a change in a transversal position of the light beam in the sensor region of the at least one transversal optical sensor. Thus, for
35 example by detecting a transversal position of a light spot generated by the light beam impinging on a sensor region, such as a sensor area, of the transversal optical sensor, the transversal position or at least one item of information on the transversal position of the object may be generated. Thus, the position of the light spot may be determined by comparing currents and/or voltage signals of partial electrodes of the transversal optical sensor, such as by
40 forming at least one ratio of at least two currents through at least two different partial electrodes. For this measurement principle, as an example, reference may be made to US 6,995,445 and/or US 2007/0176165 A1. The above-mentioned at least one relationship between the at

least one transversal sensor signal and the at least one item of information on the transversal position of the object may include a known relationship between a transversal position of the light spot on a sensor region of the transversal optical sensor and a transversal position of the object. For this purpose, known imaging properties of the detector, specifically known imaging properties of at least one transfer device of the detector, may be used. Thus, as an example, the transfer device may include at least one lens, and the known imaging properties may make use of a known lens equation of the lens, thereby allowing for a transformation of at least one transversal coordinate of a light spot into at least one transversal coordinate of the object, as the skilled person will recognize. Therein, the known relationship may also make use of additional information, such as the at least one longitudinal sensor signal and/or the at least one item of information on the longitudinal position of the object. Thus, by using the at least one longitudinal sensor signal, the evaluation device may, as an example, first determine at least one item of information on a lateral position of the object, such as at least one distance between the object and the detector, specifically the transfer device and, more preferably, at least one lens of the transfer device. This item of information on the longitudinal position of the object may then be used in the lens equation in order to transform the at least one transversal sensor signal into the at least one item of information on the transversal position of the object, such as by transforming the at least one transversal coordinate of the light spot in the sensor region of the at least one transversal optical sensor into at least one transversal coordinate of the object. Other algorithms are feasible.

As outlined above, the total intensity of total power of the light beam is often unknown, since this total power e.g. may depend on the properties of the object, such as reflecting properties, and/or may depend on a total power of an illumination source and/or may depend on a large number of environmental conditions. Since the above-mentioned known relationship between the at least one longitudinal optical sensor signal and a beam cross-section of the light beam in the at least one sensor region of the at least one longitudinal optical sensor and, thus, a known relationship between the at least one longitudinal optical sensor signal and the at least one item of information on the longitudinal position of the object may depend on the total power of total intensity of the light beam, various ways of overcoming this uncertainty are feasible. Thus, as outlined in great detail in WO 2012/110924 A1, a plurality of longitudinal sensor signals may be detected by the same longitudinal optical sensor, such as by using different modulation frequencies of an illumination of the object. Thus, at least two longitudinal sensor signals may be acquired at different frequencies of a modulation of the illumination, wherein, from the at least two sensor signals, for example by comparison with corresponding calibration curves, it is possible to deduce the total power and/or the geometry of the illumination, and/or therefrom, directly or indirectly, to deduce the at least one item of information on the longitudinal position of the object.

Additionally or alternatively, however, as outlined above, the detector may comprise a plurality of longitudinal optical sensors, each longitudinal optical sensor being adapted to generate at least one longitudinal sensor signal. The longitudinal sensor signals generated by the

longitudinal optical sensors may be compared, in order to gain information on the total power and/or intensity of the light beam and/or in order to normalize the longitudinal sensor signals and/or the at least one item of information on the longitudinal position of the object for the total power and/or total intensity of the light beam. Thus, as an example, a maximum value of the longitudinal optical sensor signals may be detected, and all longitudinal sensor signals may be divided by this maximum value, thereby generating normalized longitudinal optical sensor signals, which, then, may be transformed by using the above-mentioned known relationship, into the at least one item of longitudinal information on the object. Other ways of normalization are feasible, such as a normalization using a mean value of the longitudinal sensor signals and dividing all longitudinal sensor signals by the mean value. Other options are possible. Each of these options is suited to render the transformation independent from the total power and/or intensity of the light beam. In addition, information on the total power and/or intensity of the light beam might be generated.

The detector described can advantageously be developed in various ways. Thus, the detector can furthermore have at least one modulation device for modulating the illumination, in particular for periodic modulation, in particular a periodic beam interrupting device. A modulation of the illumination should be understood to mean a process in which a total power of the illumination is varied, preferably periodically, in particular with one or a plurality of modulation frequencies. In particular, a periodic modulation can be effected between a maximum value and a minimum value of the total power of the illumination. The minimum value can be 0, but can also be > 0 , such that, by way of example, complete modulation does not have to be effected. The modulation can be effected for example in a beam path between the object and the optical sensor, for example by the at least one modulation device being arranged in said beam path. Alternatively or additionally, however, the modulation can also be effected in a beam path between an optional illumination source - described in even greater detail below - for illuminating the object and the object, for example by the at least one modulation device being arranged in said beam path. A combination of these possibilities is also conceivable. The at least one modulation device can comprise for example a beam chopper or some other type of periodic beam interrupting device, for example comprising at least one interrupter blade or interrupter wheel, which preferably rotates at constant speed and which can thus periodically interrupt the illumination. Alternatively or additionally, however, it is also possible to use one or a plurality of different types of modulation devices, for example modulation devices based on an electro-optical effect and/or an acousto-optical effect. Once again alternatively or additionally, the at least one optional illumination source itself can also be designed to generate a modulated illumination, for example by said illumination source itself having a modulated intensity and/or total power, for example a periodically modulated total power, and/or by said illumination source being embodied as a pulsed illumination source, for example as a pulsed laser. Thus, by way of example, the at least one modulation device can also be wholly or partly integrated into the illumination source. Various possibilities are conceivable.

The detector can be designed in particular to detect at least two sensor signals in the case of different modulations, in particular at least two sensor signals at respectively different modulation frequencies. The evaluation device can be designed to generate the geometrical information from the at least two sensor signals. As described above, in this way, by way of example, it is possible to resolve ambiguities and/or it is possible to take account of the fact that, for example, a total power of the illumination is generally unknown.

Further possible embodiments of the detector relate to the embodiment of the at least one optional transfer device. As explained above, said at least one transfer device can have imaging properties or else can be embodied as a pure non-imaging transfer device, which has no influence on a focusing of the illumination. It is particularly preferred, however, if the transfer device has at least one imaging element, for example at least one lens and/or at least one curved mirror, since, in the case of such imaging elements, for example, a geometry of the illumination on the sensor region can be dependent on a relative positioning, for example a distance, between the transfer device and the object. Generally, it is particularly preferred if the transfer device is designed in such a way that the electromagnetic radiation which emerges from the object is transferred completely to the sensor region, for example is focused completely onto the sensor region, in particular the sensor area, in particular if the object is arranged in a visual range of the detector.

As explained above, the optical sensor can furthermore be designed in such a way that the sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination. The detector can be embodied, in particular, as explained above, in such a way that sensor signals at different modulation frequencies are picked up, for example in order to generate one or a plurality of further items of information about the object. As described above, by way of example, a sensor signal at at least two different modulation frequencies can, in each case, be picked up, wherein, by way of example, in this way, a lack of information about a total power of the illumination can be supplemented. By way of example, by comparing the at least two sensor signals picked up at different modulation frequencies with one or a plurality of calibration curves, which can be stored for example in a data storage device of the detector, even in the case of an unknown total power of the illumination, it is possible to deduce a geometry of the illumination, for example a diameter or an equivalent diameter of a light spot on the sensor area. For this purpose, by way of example, it is possible to use the at least one evaluation device described above, for example at least one data processing data, which can be designed to control such picking-up of sensor signals at different frequencies and which can be designed to compare said sensor signals with the at least one calibration curve in order to generate therefrom the geometrical information, for example information about a geometry of the illumination, for example information about a diameter or equivalent diameter of a light spot of the illumination on a sensor area of the optical sensor. Furthermore, as is explained in even greater detail below, the evaluation device can alternatively or additionally be designed to generate at least one item of geometrical information about the object, for example at least one item of location information. This generation of the at

least one item of geometrical information, as explained above, can be effected for example taking account of at least one known relationship between a positioning of the object relative to the detector and/or the transfer device or a part thereof and a size of a light spot, for example empirically, semi-empirically or analytically using corresponding imaging equations.

5 In contrast to known detectors, in which a spatial resolution and/or imaging of objects is also generally tied to the fact that the smallest possible sensor areas are used, for example the smallest possible pixels in the case of CCD chips, the sensor region of the proposed detector can be embodied in a very large fashion, in principle, since for example the geometrical
10 information, in particular the at least one item of location information, about the object can be generated from a known relationship for example between the geometry of the illumination and the sensor signal. Accordingly, the sensor region can have for example a sensor area, for example an optical sensor area, which is at least 0.001 mm^2 , in particular at least 0.01 mm^2 , preferably at least 0.1 mm^2 , more preferably at least 1 mm^2 , more preferably at least 5 mm^2 ,
15 more preferably at least 10 mm^2 , in particular at least 100 mm^2 or at least 1000 mm^2 or even at least $10\,000 \text{ mm}^2$. In particular, sensor areas of 100 cm^2 or more can be used. The sensor area can generally be adapted to the application. In particular, the sensor area should be chosen in such a way that, at least if the object is situated within a visual range of the detector, preferably within a predefined viewing angle and/or a predefined distance from the detector, the light spot
20 is always arranged within the sensor area. In this way, it can be ensured that the light spot is not trimmed by the limits of the sensor region, as a result of which signal corruption could occur.

As described above, the sensor region can be in particular a continuous sensor region, in particular a continuous sensor area, which can preferably generate a uniform, in particular a
25 single, sensor signal. Consequently, the sensor signal can be in particular a uniform sensor signal for the entire sensor region, that is to say a sensor signal to which each partial region of the sensor region contributes, for example additively. The sensor signal can generally, as explained above, in particular be selected from the group consisting of a photocurrent and a photo voltage.

30 The optical sensor can comprise in particular at least one semiconductor detector and/or be at least one semiconductor detector. In particular, the optical sensor can comprise at least one organic semiconductor detector or be at least one organic semiconductor detector, that is to say a semiconductor detector comprising at least one organic semiconducting material and/or at
35 least one organic sensor material, for example at least one organic dye. Preferably, the organic semiconductor detector can comprise at least one organic solar cell and particularly preferably a dye solar cell, in particular a solid dye solar cell. Exemplary embodiments of such preferred solid dye solar cells are explained in even greater detail below.

40 In particular, the optical sensor can comprise at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably at least one solid p-semiconducting organic material, and at least one second

electrode. Generally, however, it is pointed out that the described effect in which the sensor signal, given a constant total power, is dependent on a geometry of the illumination of the sensor region is with high probability not restricted to organic solar cells and in particular not to dye solar cells. Without intending to restrict the scope of protection of the invention by this theory, and without the invention being bound to the correctness of this theory, it is supposed that generally photovoltaic elements are suitable as optical sensors in which at least one semiconducting material having trap states is used. Consequently, the optical sensor can comprise at least one n-semiconducting material and/or at least one p-semiconducting material which can have for example a conduction band and a valence band, wherein, in the case of organic materials, conduction band and valence band should correspondingly be replaced by LUMO (lowest unoccupied molecular orbital) and HOMO (highest occupied molecular orbital). Trap states should be understood to mean energetically possible states which are disposed between the conduction band (or LUMO) and the valence band (or HOMO) and which can be occupied by charge carriers. By way of example, it is possible to provide trap states for hole conduction which are disposed at at least one distance ΔE_h above the valence band (or HOMO) and/or trap states for electron conduction which are disposed at at least one distance ΔE_e below the conduction band (or LUMO). Such traps can be achieved for example by impurities and/or defects, which can optionally also be introduced in a targeted manner, or can be present intrinsically. By way of example, in the case of a low intensity, that is to say for example in the case of a light spot having a large diameter, only a low current can flow, since firstly the trap states are occupied before holes in the conduction band or electrons in the valence band contribute to a photocurrent. It is only starting from a higher intensity, that is to say for example starting from a more intense focusing of the light spot in the sensor region, that a considerable photocurrent can then flow. The described frequency dependence can be explained for example by the fact that charge carriers leave the traps again after a residence duration τ , such that the described effect occurs only in the case of modulated illumination with a high modulation frequency.

By way of example, the detector can be designed to bring about a modulation of the illumination of the object and/or at least one sensor region of the detector, such as at least one sensor region of the at least one longitudinal optical sensor, with a frequency of 0.05 Hz to 1 MHz, such as 0.1 Hz to 10 kHz. As outlined above, for this purpose, the detector may comprise at least one modulation device, which may be integrated into the at least one optional illumination source and/or may be independent from the illumination source. Thus, at least one illumination source might, by itself, be adapted to generate the above-mentioned modulation of the illumination, and/or at least one independent modulation device may be present, such as at least one chopper and/or at least one device having a modulated transmissibility, such as at least one electro-optical device and/or at least one acousto-optical device.

The above-mentioned trap states can be present for example with a density of 10^{-5} to 10^{-1} , relative to the n-semiconducting material and/or the p-semiconducting material and/or the dye.

The energy differences ΔE with respect to the conduction band and with respect to the valence band can be in particular 0.05-0.3 eV.

The detector has, as described above, at least one evaluation device. In particular, the at least one evaluation device can also be designed to completely or partly control or drive the detector, for example by the evaluation device being designed to control one or a plurality of modulation devices of the detector and/or to control at least one illumination source of the detector. The evaluation device can be designed, in particular, to carry out at least one measurement cycle in which one or a plurality of sensor signals, such as a plurality of longitudinal sensor signals, are picked up, for example a plurality of sensor signals of successively at different modulation frequencies of the illumination.

However, unlike in conventional semiconductor devices in which, e.g. the absorption of incident light may occur in a p-type conductor, the absorption of incident light in the present detector may be spatially separated from the movement of the charge carriers in dye sensitized solar cells (DSCs), where incident light may cause the light-absorbing organic dye to switch into an excited state such as Frenkel excitons, i.e. excited, strongly bound electron-hole pairs. As long as the energy levels of both the p-type conductor and the n-type conductor are well-matched to the energy states of the excited light-absorbing organic dye, the excitons may be separated and, thus, the electrons and the holes may travel through the n-type and the p-type conductor, respectively, to the appropriate contact electrodes. Hereby, the moving charge carriers may be majority charge carriers, i.e. in the n-type conductor electrons, in the p-type conductor holes are traveling. Since the light-absorbing organic dye itself is a non-conducting substance, an effective charge transport may depend on an extent to which molecules of the light-absorbing organic dye are in close contact with both the p-type conductor and the n-type conductor. For potential details of DSCs, reference may be made e.g. to U. Bach, M. Grätzel, D. Lupo, P. Comte, J. E. Moser, F. Weissörtel, J. Salbeck, and H. Spreitzer. "Solid-state dye-sensitized mesoporous TiO₂ solar cells with high proton-to-electron conversion efficiencies". *Nature*, Vol. 395, no. 6702, pp. 583-585, 1998.

As described above, when light falls on the cell, it may be absorbed by the light-absorbing organic dye and an exciton may be created. If the energy of the absorbed photons is greater than an energy gap between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) of the light-absorbing organic dye, an electron of the HOMO may be raised to the LUMO of the photoexcited dye and charge separation may take place at the boundary between the dye and the semiconductor which nanoporous titanium dioxide. From there, the electron may travel within femtoseconds to picoseconds further into the conduction band of nanoporous titanium dioxide. Preferably, the energy level of the excited state is matched to the lower limit of the conduction band of the titanium dioxide in order to minimize energy losses during electron transition and the LUMO level should extend sufficiently beyond the lower limit of the conduction band of the titanium dioxide. The oxidation potential of the hole conductor should extend over the HOMO level of the dye allowing it to transport away

the holes of the excited dye. If a load is connected in an external circuit, a current may flow across the titanium dioxide and the anode. The reduced dye may be regenerated through electron donation by the organic p-type conductor to the dye, which may prevent recombination of the electrons from the conduction band of the titanium dioxide with the oxidised dye. The p-type conductor, in turn, may be regenerated through the counter-electrode, which may ensure a constant conversion of energy from incident light into electrical energy without requiring a permanent chemical change.

The evaluation device is designed, as described above, to generate at least one item of information on a transversal position of the object by evaluating the transversal sensor signal and to generate at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal. Said position of the object can be static or may even comprise at least one movement of the object, for example a relative movement between the detector or parts thereof and the object or parts thereof. In this case, a relative movement can generally comprise at least one linear movement and/or at least one rotational movement. Items of movement information can for example also be obtained by comparison of at least two items of information picked up at different times, such that for example at least one item of location information can also comprise at least one item of velocity information and/or at least one item of acceleration information, for example at least one item of information about at least one relative velocity between the object or parts thereof and the detector or parts thereof. In particular, the at least one item of location information can generally be selected from: an item of information about a distance between the object or parts thereof and the detector or parts thereof, in particular an optical path length; an item of information about a distance or an optical distance between the object or parts thereof and the optional transfer device or parts thereof; an item of information about a positioning of the object or parts thereof relative to the detector or parts thereof; an item of information about an orientation of the object and/or parts thereof relative to the detector or parts thereof; an item of information about a relative movement between the object or parts thereof and the detector or parts thereof; an item of information about a two-dimensional or three-dimensional spatial configuration of the object or of parts thereof, in particular a geometry or form of the object. Generally, the at least one item of location information can therefore be selected for example from the group consisting of: an item of information about at least one location of the object or at least one part thereof; information about at least one orientation of the object or a part thereof; an item of information about a geometry or form of the object or of a part thereof, an item of information about a velocity of the object or of a part thereof, an item of information about an acceleration of the object or of a part thereof, an item of information about a presence or absence of the object or of a part thereof in a visual range of the detector.

The at least one item of location information can be specified for example in at least one coordinate system, for example a coordinate system in which the detector or parts thereof rest. Alternatively or additionally, the location information can also simply comprise for example a

distance between the detector or parts thereof and the object or parts thereof. Combinations of the possibilities mentioned are also conceivable.

As outlined above, the detector may comprise at least one illumination source. The illumination source can be embodied in various ways. Thus, the illumination source can be for example part of the detector in a detector housing. Alternatively or additionally, however, the at least one illumination source can also be arranged outside a detector housing, for example as a separate light source. The illumination source can be arranged separately from the object and illuminate the object from a distance. Alternatively or additionally, the illumination source can also be connected to the object or even be part of the object, such that, by way of example, the electromagnetic radiation emerging from the object can also be generated directly by the illumination source. By way of example, at least one illumination source can be arranged on and/or in the object and directly generate the electromagnetic radiation by means of which the sensor region is illuminated. By way of example, at least one infrared emitter and/or at least one emitter for visible light and/or at least one emitter for ultraviolet light can be arranged on the object. By way of example, at least one light emitting diode and/or at least one laser diode can be arranged on and/or in the object. The illumination source can comprise in particular one or a plurality of the following illumination sources: a laser, in particular a laser diode, although in principle, alternatively or additionally, other types of lasers can also be used; a light emitting diode; an incandescent lamp; an organic light source, in particular an organic light emitting diode. Alternatively or additionally, other illumination sources can also be used. It is particularly preferred if the illumination source is designed to generate one or more light beams having a Gaussian beam profile, as is at least approximately the case for example in many lasers. However, other embodiments are also possible, in principle.

As outlined above, a further aspect of the present invention proposes a human-machine interface for exchanging at least one item of information between a user and a machine. A human-machine interface should generally be understood to mean a device by means of which such information can be exchanged. The machine can comprise in particular a data processing device. The at least one item of information can generally comprise for example data and/or control commands. Thus, the human-machine interface can be designed in particular for the inputting of control commands by the user.

The human-machine interface has at least one detector in accordance with one or a plurality of the embodiments described above. The human-machine interface is designed to generate at least one item of geometrical information of the user by means of the detector wherein the human-machine interface is designed to assign to the geometrical information at least one item of information, in particular at least one control command. By way of example, said at least one item of geometrical information can be or comprise an item of location information and/or position information and/or orientation information about a body and/or at least one body part of the user, for example an item of location information about a hand posture and/or a posture of some other body part of the user.

In this case, the term user should be interpreted broadly and can for example also encompass one or a plurality of articles directly influenced by the user. Thus, the user can for example also wear one or a plurality of gloves and/or other garments, wherein the geometrical information is at least one item of geometrical information of this at least one garment. By way of example, such garments can be embodied as reflective to a primary radiation emerging from at least one illumination source, for example by the use of one or a plurality of reflectors. Once again alternatively or additionally, the user can for example spatially move one or a plurality of articles whose geometrical information can be detected, which is likewise also intended to be subsumable under generation of at least one item of geometrical information of the user. By way of example, the user can move at least one reflective rod and/or some other type of article, for example by means of said user's hand.

The at least one item of geometrical information can be static, that is to say can for example once again comprise a snapshot, but can also for example once again comprise a series of sequential items of geometrical information and/or at least one movement. By way of example, at least two items of geometrical information picked up at different times can be compared, such that, by way of example, the at least one item of geometrical information can also comprise at least one item of information about a velocity and/or an acceleration of a movement. Accordingly, the at least one item of geometrical information can for example comprise at least one item of information about at least one body posture and/or about at least one movement of the user.

The human-machine interface is designed to assign to the geometrical information at least one item of information, in particular at least one control command. As explained above, the term information should in this case be interpreted broadly and can comprise for example data and/or control commands. By way of example, the human-machine interface can be designed to assign the at least one item of information to the at least one item of geometrical information, for example by means of a corresponding assignment algorithm and/or a stored assignment specification. By way of example, a unique assignment between a set of items of geometrical information and corresponding items of information can be stored. In this way, for example by means of a corresponding body posture and/or movement of the user, an inputting of at least one item of information can be effected.

Such human-machine interfaces can generally be used in the machine control or else for example in virtual reality. By way of example, industrial controllers, manufacturing controllers, machine controllers in general, robot controllers, vehicle controllers or similar controllers can be made possible by means of the human-machine interface having the one or the plurality of detectors. However, the use of such a human-machine interface in consumer electronics is particularly preferred.

Accordingly, as outlined above, a further aspect of the present invention proposes an entertainment device for carrying out at least one entertainment function, in particular a game. The entertainment function can comprise in particular at least one game function. By way of example, one or a plurality of games can be stored which can be influencable by a user, who in this context is also called a player hereinafter. By way of example, the entertainment device can comprise at least one display device, for example at least one screen and/or at least one projector and/or at least one set of display spectacles.

The entertainment device furthermore comprises at least one human-machine interface in accordance with one or more of the embodiments described above. The entertainment device is designed to enable at least one item of information of a player to be input by means of the human-machine interface. By way of example, the player, as described above, can adopt or alter one or a plurality of body postures for this purpose. This includes the possibility of the player for example using corresponding articles for this purpose, for example garments such as e.g. gloves, for example garments which are equipped with one or a plurality of reflectors for reflecting the electromagnetic radiation of the detector. The at least one item of information can comprise for example, as explained above, one or a plurality of control commands. By way of example, in this way, changes in direction can be performed, inputs can be confirmed, a selection can be made from a menu, specific game options can be initiated, movements can be influenced in a virtual space or similar instances of influencing or altering the entertainment function can be performed.

The above-described detector, the method, the human-machine interface and the entertainment device and also the proposed uses have considerable advantages over the prior art. Thus, generally, a simple and, still, efficient detector for determining a position of at least one object in space may be provided. Therein, as an example, three-dimensional coordinates of an object or part of an object may be determined in a fast and efficient way. Specifically the combination of the at least one transversal optical sensor and the at least one longitudinal optical sensor, which each may be designed in a cost-efficient way, may lead to a compact, cost-efficient and, still, highly precise device. Both the at least one transversal optical sensor and the at least one longitudinal optical sensor preferably may fully or partially be designed as organic photovoltaic devices, such as by using dye-sensitized solar cells for each of these optical sensors, preferably sDSCs.

As compared to devices known in the art, which of them are based on complex triangulation methods, the detector as proposed provides a high degree of simplicity, specifically with regard to an optical setup of the detector. Thus, in principle, a simple combination of one, two or more sDSCs, preferably in combination with a suited transfer device, specifically a suited lens, and in conjunction with an appropriate evaluation device, is sufficient for high precision position detection.

This high degree of simplicity, in combination with the possibility of high precision measurements, is specifically suited for machine control, such as in human-machine interfaces and, more preferably, in gaming. Thus, cost-efficient entertainment devices may be provided which may be used for a large number of gaming purposes.

5

Thus, as for the optical detectors and devices disclosed in WO 2012/110924 A1 or in US provisional applications 61/739,173, filed on December 19, 2012, and 61/749,964, filed on January 8, 2013, the optical detector, the detector system, the human-machine interface, the entertainment device, the tracking system or the camera according to the present invention (in
10 the following simply referred to as “the devices according to the present invention” or “Fip-devices”) may be used for a plurality of application purposes, such as one or more of the purposes disclosed in further detail in the following.

Thus, firstly, Fip-devices may be used in mobile phones, tablet computers, laptops, smart
15 panels or other stationary or mobile computer or communication applications. Thus, Fip-devices may be combined with at least one active light source, such as a light source emitting light in the visible range or infrared spectral range, in order to enhance performance. Thus, as an example, Fip-devices may be used as cameras and/or sensors, such as in combination with mobile software for scanning environment, objects and living beings. Fip-devices may even be
20 combined with 2D cameras, such as conventional cameras, in order to increase imaging effects. Fip-devices may further be used for surveillance and/or for recording purposes or as input devices to control mobile devices, especially in combination with gesture recognition. Thus, specifically, Fip-devices acting as human-machine interfaces, also referred to as FiP input devices, may be used in mobile applications, such as for controlling other electronic devices or
25 components via the mobile device, such as the mobile phone. As an example, the mobile application including at least one Fip-device may be used for controlling a television set, a game console, a music player or music device or other entertainment devices.

Further, Fip-devices may be used in webcams or other peripheral devices for computing
30 applications. Thus, as an example, Fip-devices may be used in combination with software for imaging, recording, surveillance, scanning or motion detection. As outlined in the context of the human-machine interface and/or the entertainment device, Fip-devices are particularly useful for giving commands by facial expressions and/or body expressions. Fip-devices can be combined with other input generating devices like e.g. mouse, keyboard, touchpad, etc. Further,
35 Fip-devices may be used in applications for gaming, such as by using a webcam. Further, Fip-devices may be used in virtual training applications and/or video conferences.

Further, Fip-devices may be used in mobile audio devices, television devices and gaming
40 devices, as partially explained above. Specifically, Fip-devices may be used as controls or control devices for electronic devices, entertainment devices or the like. Further, Fip-devices may be used for eye detection or eye tracking, such as in 2D- and 3D-display techniques, especially with transparent displays for augmented reality applications.

Further, Fip-devices may be used in or as digital cameras such as DSC cameras and/or in or as reflex cameras such as SLR cameras. For these applications, reference may be made to the use of Fip-devices in mobile applications such as mobile phones, as disclosed above.

5

Further, Fip-devices may be used for security and surveillance applications. Specifically, Fip-devices may be used for optical encryption. FIP-based detection can be combined with other detection devices to complement wavelengths, such as with IR, x-ray, UV-VIS, radar or ultrasound detectors. Fip-devices may further be combined with an active infrared light source to allow detection in low light surroundings. Fip-devices such as FIP-based sensors are generally advantageous as compared to active detector systems, specifically since Fip-devices avoid actively sending signals which may be detected by third parties, as is the case e.g. in radar applications, ultrasound applications, LIDAR or similar active detector device is. Thus, generally, Fip-devices may be used for an unrecognized and undetectable tracking of moving objects. Additionally, Fip-devices generally are less prone to manipulations and irritations as compared to conventional devices.

Further, given the ease and accuracy of 3D detection by using Fip-devices, Fip-devices generally may be used for facial, body and person recognition and identification. Therein, Fip-devices may be combined with other detection means for identification or personalization purposes such as passwords, finger prints, iris detection, voice recognition or other means. Thus, generally, Fip-devices may be used in security devices and other personalized applications.

Further, Fip-devices may be used as 3D-Barcode readers for product identification.

In addition to the security and surveillance applications mentioned above, Fip-devices generally can be used for surveillance and monitoring of spaces and areas. Thus, Fip-devices may be used for surveying and monitoring spaces and areas and, as an example, for triggering or executing alarms in case prohibited areas are violated. Thus, generally, Fip-devices may be used for surveillance purposes in building surveillance or museums, optionally in combination with other types of sensors, such as in combination with motion or heat sensors, in combination with image intensifiers or image enhancement devices and/or photomultipliers.

Further, Fip-devices may advantageously be applied in camera applications such as video and camcorder applications. Thus, Fip-devices may be used for motion capture and 3D-movie recording. Therein, Fip-devices generally provide a large number of advantages over conventional optical devices. Thus, Fip-devices generally require a lower complexity with regard to optical components. Thus, as an example, the number of lenses may be reduced as compared to conventional optical devices, such as by providing Fip-devices having one lens only. Due to the reduced complexity, very compact devices are possible, such as for mobile use. Conventional optical systems having two or more lenses with high quality generally are

voluminous, such as due to the general need for voluminous beam-splitters. Further, Fip-devices generally may be used for focus/autofocus devices, such as autofocus cameras. Further, Fip-devices may also be used in optical microscopy, especially in confocal microscopy.

5 Further, Fip-devices generally are applicable in the technical field of automotive technology and transport technology. Thus, as an example, Fip-devices may be used as distance and surveillance sensors, such as for adaptive cruise control, emergency brake assist, lane departure warning, surround view, blind spot detection, rear cross traffic alert, and other automotive and traffic applications. Therein, Fip-devices may be used as standalone devices or
10 in combination with other sensor devices, such as in combination with radar and/or ultrasonic devices. Specifically, Fip-devices may be used for autonomous driving and safety issues. Further, in these applications, Fip-devices may be used in combination with infrared sensors, radar sensors, which are sonic sensors, two-dimensional cameras or other types of sensors. Advantage, in these applications, the generally passive nature of typical Fip-devices is
15 advantageous. Thus, since Fip-devices generally do not require emitting signals, the risk of interference of active sensor signals with other signal sources may be avoided. Fip-devices specifically may be used in combination with recognition software, such as standard image recognition software. Thus, signals and data as provide by Fip-devices typically are readily processable and, therefore, generally require lower calculation power than established
20 stereovision systems such as LIDAR. Given the low space demand, Fip-devices such as cameras using the FiP-effect may be placed at virtually any place in a vehicle, such as on a window screen, on a front hood, on bumpers, on lights, on mirrors or other places the like. Various detectors based on the FiP-effect can be combined, such as in order to allow autonomously driving vehicles or in order to increase the performance of active safety concepts.
25 Thus, various FiP-based sensors may be combined with other Fip-based sensors and/or conventional sensors, such as in the windows like rear window, side window or front window, on the bumpers or on the lights.

A combination of a FiP-sensor with one or more rain detection sensors is also possible. This is
30 due to the fact that Fip-devices generally are advantageous over conventional sensor techniques such as radar, specifically during heavy rain. A combination of at least one Fip-device with at least one conventional sensing technique such as radar may allow for a software to pick the right combination of signals according to the weather conditions.

35 Further, Fip-devices generally may be used as break assist and/or parking assist and/or for speed measurements. Speed measurements can be integrated in the vehicle or may be used outside the vehicle, such as in order to measure the speed of other cars in traffic control. Further, Fip-devices may be used for detecting free parking spaces in parking lots.

40 Further, Fip-devices may be used is the fields of medical systems and sports. Thus, in the field of medical technology, surgery robotics, e.g. for use in endoscopes, may be named, since, as outlined above, Fip-devices may require a low volume only and may be integrated into other

devices. Specifically, Fip-devices having one lens, at most, may be used for capturing 3D information in medical devices such as in endoscopes. Further, Fip-devices may be combined with an appropriate monitoring software, in order to enable tracking and analysis of movements. These applications are specifically valuable e.g. in medical treatments and long-distance diagnosis and tele-medicine.

Further, Fip-devices may be applied in the field of sports and exercising, such as for training, remote instructions or competition purposes. Specifically, Fip-devices may be applied in the field of dancing, aerobic, football, soccer, basketball, baseball, cricket, hockey, track and field, swimming, polo, handball, volleyball, rugby, sumo, judo, fencing, boxing etc. Fip-devices can be used to detect the position of a ball, a bat, a sword, motions, etc., both in sports and in games, such as to monitor the game, support the referee or for judgment, specifically automatic judgment, of specific situations in sports, such as for judging whether a point or a goal actually was made.

FIP devices may further be used to support a practice of musical instruments, in particular remote lessons, for example lessons of string instruments, such as fiddles, violins, violas, celli, basses, harps, guitars, banjos, or ukuleles, keyboard instruments, such as pianos, organs, keyboards, harpsichords, harmoniums, or accordions, and/or percussion instruments, such as drums, timpani, marimbas, xylophones, vibraphones, bongos, congas, timbales, djembes or tablas.

Fip-devices further may be used in rehabilitation and physiotherapy, in order to encourage training and/or in order to survey and correct movements. Therein, the Fip-devices may also be applied for distance diagnostics.

Further, Fip-devices may be applied in the field of machine vision. Thus, one or more Fip-devices may be used e.g. as a passive controlling unit for autonomous driving and or working of robots. In combination with moving robots, Fip-devices may allow for autonomous movement and/or autonomous detection of failures in parts. Fip-devices may also be used for manufacturing and safety surveillance, such as in order to avoid accidents including but not limited to collisions between robots, production parts and living beings. Given the passive nature of Fip-devices, Fip-devices may be advantageous over active devices and/or may be used complementary to existing solutions like radar, ultrasound, 2D cameras, IR detection etc. One particular advantage of Fip-devices is the low likelihood of signal interference. Therefore multiple sensors can work at the same time in the same environment, without the risk of signal interference. Thus, Fip-devices generally may be useful in highly automated production environments like e.g. but not limited to automotive, mining, steel, etc. Fip-devices can also be used for quality control in production, e.g. in combination with other sensors like 2-D imaging, radar, ultrasound, IR etc., such as for quality control or other purposes. Further, Fip-devices may be used for assessment of surface quality, such as for surveying the surface evenness of a

product or the adherence to specified dimensions, from the range of micrometers to the range of meters. Other quality control applications are feasible.

Further, Fip-devices may be used in the polls, airplanes, ships, spacecrafts and other traffic applications. Thus, besides the applications mentioned above in the context of traffic applications, passive tracking systems for aircrafts, vehicles and the like may be named. Detection devices based on the FiP-effect for monitoring the speed and/or the direction of moving objects are feasible. Specifically, the tracking of fast moving objects on land, sea and in the air including space may be named. The at least one Fip-detector specifically may be mounted on a still-standing and/or on a moving device. An output signal of the at least one Fip-device can be combined e.g. with a guiding mechanism for autonomous or guided movement of another object. Thus, applications for avoiding collisions or for enabling collisions between the tracked and the steered object are feasible. Fip-devices generally are useful and advantageous due to the low calculation power required, the instant response and due to the passive nature of the detection system which generally is more difficult to detect and to disturb as compared to active systems, like e.g. radar. Fip-devices are particularly useful but not limited to e.g. speed control and air traffic control devices.

Fip-devices generally may be used in passive applications. Passive applications include guidance for ships in harbors or in dangerous areas, and for aircrafts at landing or starting. Wherein, fixed, known active targets may be used for precise guidance. The same can be used for vehicles driving in dangerous but well defined routes, such as mining vehicles.

Further, as outlined above, Fip-devices may be used in the field of gaming. Thus, Fip-devices can be passive for use with multiple objects of the same or of different size, color, shape, etc., such as for movement detection in combination with software that incorporates the movement into its content. In particular, applications are feasible in implementing movements into graphical output. Further, applications of Fip-devices for giving commands are feasible, such as by using one or more Fip-devices for gesture or facial recognition. Fip-devices may be combined with an active system in order to work under e.g. low light conditions or in other situations in which enhancement of the surrounding conditions is required. Additionally or alternatively, a combination of one or more Fip-devices with one or more IR or VIS light sources is possible, such as with a detection device based on the FiP effect. A combination of a FiP-based detector with special devices is also possible, which can be distinguished easily by the system and its software, e.g. and not limited to, a special color, shape, relative position to other devices, speed of movement, light, frequency used to modulate light sources on the device, surface properties, material used, reflection properties, transparency degree, absorption characteristics, etc. The device can, amongst other possibilities, resemble a stick, a racquet, a club, a gun, a knife, a wheel, a ring, a steering wheel, a bottle, a ball, a glass, a vase, a spoon, a fork, a cube, a dice, a figure, a puppet, a teddy, a beaker, a pedal, a switch, a glove, jewelry, a musical instrument or an auxiliary device for playing a musical instrument, such as a plectrum, a drumstick or the like. Other options are feasible.

Further, Fip-devices generally may be used in the field of building, construction and cartography. Thus, generally, FiP-based devices may be used in order to measure and/or monitor environmental areas, e.g. country side or buildings. Therein, one or more Fip-devices may be combined with other methods and devices or can be used solely in order to monitor progress and accuracy of building projects, changing objects, houses, etc. FiP-devices can be used for generating three-dimensional models of scanned environments, in order to construct maps of rooms, streets, houses, communities or landscapes, both from ground or from air. Potential fields of application may be construction, cartography, real estate management, land surveying or the like.

FiP-devices may be used within an interconnecting network of home appliances such as CHAIN (Cedec Home Appliances Interoperating Network) to interconnect, automate, and control basic appliance-related services in a home, e.g. energy or load management, remote diagnostics, pet related appliances, child related appliances, child surveillance, appliances related surveillance, support or service to elderly or ill persons, home security and/or surveillance, remote control of appliance operation, and automatic maintenance support.

FiP devices may further be used in agriculture, for example to detect and sort out vermin, weeds, and/or infected crop plants, fully or in parts, wherein crop plants may be infected by fungus or insects. Further, for harvesting crops, FiP detectors may be used to detect animals, such as deer, which may otherwise be harmed by harvesting devices.

FiP-based devices can further be used for scanning of objects, such as in combination with CAD or similar software, such as for additive manufacturing and/or 3D printing. Therein, use may be made of the high dimensional accuracy of Fip-devices, e.g. in x-, y- or z- direction or in any arbitrary combination of these directions, such as simultaneously. Further, Fip-devices may be used in inspections and maintenance, such as pipeline inspection gauges.

As outlined above, Fip-devices may further be used in manufacturing, quality control or identification applications, such as in product identification or size identification (such as for finding an optimal place or package, for reducing waste etc.). Further, Fip-devices may be used in logistics applications. Thus, Fip-devices may be used for optimized loading or packing containers or vehicles. Further, Fip-devices may be used for monitoring or controlling of surface damages in the field of manufacturing, for monitoring or controlling rental objects such as rental vehicles, and/or for insurance applications, such as for assessment of damages. Further, Fip-devices may be used for identifying a size of material, object or tools, such as for optimal material handling, especially in combination with robots. Further, Fip-devices may be used for process control in production, e.g. for observing filling level of tanks. Further, Fip-devices may be used for maintenance of production assets like, but not limited to, tanks, pipes, reactors, tools etc. Further, Fip-devices may be used for analyzing 3D-quality marks. Further, Fip-devices may be used in manufacturing tailor-made goods such as tooth inlays, dental braces,

prosthesis, clothes or the like. Fip-devices may also be combined with one or more 3D-printers for rapid prototyping, 3D-copying or the like. Further, Fip-devices may be used for detecting the shape of one or more articles, such as for anti-product piracy and for anti-counterfeiting purposes.

As outlined above, preferably, the at least one transversal optical sensor and/or the at least one longitudinal optical sensor both may comprise at least one organic semiconductor detector, particularly preferably at least one dye solar cell, DSC or sDSC. In particular, the transversal optical sensor and/or the longitudinal optical sensor each may comprise at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material and at least one second electrode, preferably in the stated order. The stated elements can be present as layers in a layer construction, for example. The layer construction can be applied for example to a substrate, preferably a transparent substrate, for example a glass substrate.

Preferred embodiments of the above-mentioned elements of the preferred optical sensor are described below by way of example, wherein these embodiments can be used in any desired combination. However, numerous other configurations are also possible, in principle, wherein reference can be made for example to WO 2012/110924 A1, US 2007/0176165 A1, US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1 and WO 2009/013282 A1 cited above.

As outlined above, the at least one transversal optical sensor may be designed as a dye-sensitized solar cell (DSC), preferably a solid dye-sensitized solar cell (sDSC). Similarly, the at least one longitudinal optical sensor may be designed as at least one dye-sensitized solar cell (DSC) or may comprise at least one dye-sensitized solar cell (DSC), preferably a solid dye-sensitized solar cell (sDSC). More preferably, the at least one longitudinal optical sensor comprises a stack of DSCs, preferably a stack of sDSCs. Preferred components of the DSCs or sDSCs will be disclosed in the following. However, it shall be understood that other embodiments are feasible.

First electrode and n-semiconductive metal oxide

Generally, for preferred embodiments of the first electrode and the n-semiconductive metal oxide, which may be used in a layer setup of the transversal optical sensor and/or the longitudinal optical sensor, reference may be made to WO 2012/110924 A1. The n-semiconductive metal oxide used in the dye solar cell of the transversal optical sensor and/or the longitudinal optical sensor may be a single metal oxide or a mixture of different oxides. It is also possible to use mixed oxides. The n-semiconductive metal oxide may especially be porous and/or be used in the form of a nanoparticulate oxide, nanoparticles in this context being understood to mean particles which have an average particle size of less than 0.1 micrometer. A nanoparticulate oxide is typically applied to a conductive substrate (i.e. a carrier with a

conductive layer as the first electrode) by a sintering process as a thin porous film with large surface area.

Preferably, the at least one transversal optical sensor uses at least one transparent substrate.

- 5 Similarly, preferably, the at least one longitudinal optical sensor uses at least one transparent substrate. In case a plurality of longitudinal optical sensors is used, such as a stack of longitudinal optical sensors, preferably, at least one of these longitudinal optical sensors uses a transparent substrate. Thus, as an example, all longitudinal optical sensors but the last longitudinal optical sensor facing away from the object, each may use a transparent substrate.
- 10 The last longitudinal optical sensor may either use a transparent or an intransparent substrate.

Similarly, the at least one transversal optical sensor uses at least one transparent first electrode. Further, the at least one longitudinal optical sensor may use at least one transparent first electrode. In case a plurality of longitudinal optical sensors is used, such as a stack of

15 longitudinal optical sensors, preferably, at least one of these longitudinal optical sensors uses a transparent first electrode. Thus, as an example, all longitudinal optical sensors but the last longitudinal optical sensor facing away from the object each may use a transparent first electrode. The last longitudinal optical sensor may either use a transparent or an intransparent first electrode.

20

The substrate may be rigid or else flexible. Suitable substrates (also referred to hereinafter as carriers) are, as well as metal foils, in particular plastic sheets or films and especially glass sheets or glass films. Particularly suitable electrode materials, especially for the first electrode according to the above-described, preferred structure, are conductive materials, for example

25 transparent conductive oxides (TCOs), for example fluorine- and/or indium-doped tin oxide (FTO or ITO) and/or aluminum-doped zinc oxide (AZO), carbon nanotubes or metal films. Alternatively or additionally, it would, however, also be possible to use thin metal films which still have a sufficient transparency. In case an intransparent first electrode is desired and used, thick metal films may be used.

30

The substrate can be covered or coated with these conductive materials. Since generally, only a single substrate is required in the structure proposed, the formation of flexible cells is also possible. This enables a multitude of end uses which would be achievable only with difficulty, if at all, with rigid substrates, for example use in bank cards, garments, etc.

35

The first electrode, especially the TCO layer, may additionally be covered or coated with a solid metal oxide buffer layer (for example of thickness 10 to 200 nm), in order to prevent direct contact of the p-type semiconductor with the TCO layer (see Peng *et al.*, Coord. Chem. Rev. 248, 1479 (2004)). The inventive use of solid p-semiconducting electrolytes, in the case of

40 which contact of the electrolyte with the first electrode is greatly reduced compared to liquid or gel-form electrolytes, however, makes this buffer layer unnecessary in many cases, such that it is possible in many cases to dispense with this layer, which also has a current-limiting effect

and can also worsen the contact of the n-semiconducting metal oxide with the first electrode. This enhances the efficiency of the components. On the other hand, such a buffer layer can in turn be utilized in a controlled manner in order to match the current component of the dye solar cell to the current component of the organic solar cell. In addition, in the case of cells in which the buffer layer has been dispensed with, especially in solid cells, problems frequently occur with unwanted recombinations of charge carriers. In this respect, buffer layers are advantageous in many cases specifically in solid cells.

As is well known, thin layers or films of metal oxides are generally inexpensive solid semiconductor materials (n-type semiconductors), but the absorption thereof, due to large band gaps, is typically not within the visible region of the electromagnetic spectrum, but rather usually in the ultraviolet spectral region. For use in solar cells, the metal oxides therefore generally, as is the case in the dye solar cells, have to be combined with a dye as a photosensitizer, which absorbs in the wavelength range of sunlight, i.e. at 300 to 2000 nm, and, in the electronically excited state, injects electrons into the conduction band of the semiconductor. With the aid of a solid p-type semiconductor used additionally in the cell as an electrolyte, which is in turn reduced at the counter electrode, electrons can be recycled to the sensitizer, such that it is regenerated.

Of particular interest for use in organic solar cells are semiconductors zinc oxide, tin dioxide, titanium dioxide or mixtures of these metal oxides. The metal oxides can be used in the form of nanocrystalline porous layers. These layers have a large surface area which is coated with the dye as a sensitizer, such that a high absorption of sunlight is achieved. Metal oxide layers which are structured, for example nanorods, give advantages such as higher electron mobilities or improved pore filling by the dye.

The metal oxide semiconductors can be used alone or in the form of mixtures. It is also possible to coat a metal oxide with one or more other metal oxides. In addition, the metal oxides may also be applied as a coating to another semiconductor, for example GaP, ZnP or ZnS.

Particularly preferred semiconductors are zinc oxide and titanium dioxide in the anatase polymorph, which is preferably used in nanocrystalline form.

In addition, the sensitizers can advantageously be combined with all n-type semiconductors which typically find use in these solar cells. Preferred examples include metal oxides used in ceramics, such as titanium dioxide, zinc oxide, tin(IV) oxide, tungsten(VI) oxide, tantalum(V) oxide, niobium(V) oxide, cesium oxide, strontium titanate, zinc stannate, complex oxides of the perovskite type, for example barium titanate, and binary and ternary iron oxides, which may also be present in nanocrystalline or amorphous form.

Due to the strong absorption that customary organic dyes and phthalocyanines and porphyrins have, even thin layers or films of the n-semiconducting metal oxide are sufficient to absorb the

required amount of dye. Thin metal oxide films in turn have the advantage that the probability of unwanted recombination processes falls and that the internal resistance of the dye subcell is reduced. For the n-semiconducting metal oxide, it is possible with preference to use layer thicknesses of 100 nm up to 20 micrometers, more preferably in the range between 500 nm and approx. 3 micrometers.

Dye

In the context of the present invention, as usual in particular for DSCs, the terms "dye", "sensitizer dye" and "sensitizer" are used essentially synonymously without any restriction of possible configurations. Numerous dyes which are usable in the context of the present invention are known from the prior art, and so, for possible material examples, reference may also be made to the above description of the prior art regarding dye solar cells. As a preferred example, one or more of the dyes disclosed in WO 2012/110924 A1 may be used.

Additionally or alternatively, one or more quinolinium dyes with fluorinated counter anion may be used in the detector according to the present invention, such as one or more of the dyes as disclosed in WO 2013/144177 A1. Specifically, one or more of the dyes disclosed in the following may be used in the at least one longitudinal optical sensor and/or in the at least one transversal optical sensor. Details of these dyes and details of the disclosure of these unpublished applications will be given below. Specifically, dye D-5, which will be described below in more detail, may be used. However, one or more other dyes may be used in addition or alternatively.

All dyes listed and claimed may in principle also be present as pigments. Dye-sensitized solar cells based on titanium dioxide as a semiconductor material are described, for example, in US 4 927 721 A, Nature 353, p. 737-740 (1991) and US 5 350 644 A, and also Nature 395, p. 583-585 (1998) and EP 1 176 646 A1. The dyes described in these documents can in principle also be used advantageously in the context of the present invention. These dye solar cells preferably comprise monomolecular films of transition metal complexes, especially ruthenium complexes, which are bonded to the titanium dioxide layer via acid groups as sensitizers.

Dyes for use in dye-sensitized solar cells which may comprise ruthenium complexes have been rather of academic interest so far, particularly due to the high costs of ruthenium. However, a dye-sensitized solar cell which may be used in the detector according to the present invention would only require such a small amount of ruthenium that the cost argument may easily be overruled by its attractive features for use within the present method for determining a position of at least one object, particularly in a case where at least one light beam which travels from the object might involve a spectral range which may at least partially include a part of the infrared (IR) region, i.e. a part of the electromagnetic spectrum ranging from approximately 750 nm to 1000 μ m, preferentially a part thereof generally denoted as near infrared (NIR) region, which is usually considered to range from approximately 750 nm to 1.5 μ m. Examples of known

ruthenium complexes which might be suitable for an application within the detector according to the present invention are:

5

Another example may be found in T. Kinoshita, J.T. Dy, S. Uchida, T. Kubo, and H. Segawa, *Wideband dye-sensitized solar cells employing a phosphine-coordinated ruthenium sensitizer*, Nature Photonics, 7, 535-539 (2013), wherein a phosphine-coordinated ruthenium complex is described, which exhibits a strong absorption in the NIR, particularly within the range from 750 nm to 950 nm, which may thus, yield a dye-sensitized solar cell with a promising efficiency:

10

15 Owing to weak absorption properties of most known dyes within the IR region, including the NIR region, dyes comprising ruthenium complexes may, thus, be able to extend the scope of the

detector according to the present invention into the IR region, in particular into the NIR region, e.g. as being used as active depth sensors, particularly in applications related to computer vision, wherein IR light may play an important role, as described elsewhere in this application.

5 Many sensitizers which have been proposed include metal-free organic dyes, which are likewise also usable in the context of the present invention. High efficiencies of more than 4%, especially in solid dye solar cells, can be achieved, for example, with indoline dyes (see, for example, Schmidt-Mende *et al.*, Adv. Mater. 2005, 17, 813). US-A-6 359 211 describes the use, also implementable in the context of the present invention, of cyanine, oxazine, thiazine and acridine
10 dyes which have carboxyl groups bonded via an alkylene radical for fixing to the titanium dioxide semiconductor.

Organic dyes now achieve efficiencies of almost 12.1% in liquid cells (see, for example, P. Wang *et al.*, ACS. Nano 2010). Pyridinium-containing dyes have also been reported, can be
15 used in the context of the present invention and exhibit promising efficiencies.

Particularly preferred sensitizer dyes in the dye solar cell proposed are the perylene derivatives, terrylene derivatives and quaterrylene derivatives described in DE 10 2005 053 995 A1 or WO 2007/054470 A1. The use of these dyes, which is also possible in the context of the
20 present invention, leads to photovoltaic elements with high efficiencies and simultaneously high stabilities.

The rylenes exhibit strong absorption in the wavelength range of sunlight and can, depending on the length of the conjugated system, cover a range from about 400 nm (perylene derivatives I from DE 10 2005 053 995 A1) up to about 900 nm (quaterrylene derivatives I from
25 DE 10 2005 053 995 A1). Rylene derivatives I based on terrylene absorb, according to the composition thereof, in the solid state adsorbed onto titanium dioxide, within a range from about 400 to 800 nm. In order to achieve very substantial utilization of the incident sunlight from the visible into the near infrared region, it is advantageous to use mixtures of different rylene
30 derivatives I. Occasionally, it may also be advisable also to use different rylene homologs.

The rylene derivatives I can be fixed easily and in a permanent manner to the n-semiconducting metal oxide film. The bonding is effected via the anhydride function (x1) or the carboxyl groups –COOH or –COO– formed in situ, or via the acid groups A present in the imide or condensate
35 radicals ((x2) or (x3)). The rylene derivatives I described in DE 10 2005 053 995 A1 have good suitability for use in dye-sensitized solar cells in the context of the present invention.

It is particularly preferred when the dyes, at one end of the molecule, have an anchor group which enables the fixing thereof to the n-type semiconductor film. At the other end of the
40 molecule, the dyes preferably comprise electron donors Y which facilitate the regeneration of the dye after the electron release to the n-type semiconductor, and also prevent recombination with electrons already released to the semiconductor.

For further details regarding the possible selection of a suitable dye, it is possible, for example, again to refer to DE 10 2005 053 995 A1. By way of example, it is possible especially to use ruthenium complexes, porphyrins, other organic sensitizers, and preferably rylenes.

The dyes can be fixed onto or into the n-semiconducting metal oxide films in a simple manner. For example, the n-semiconducting metal oxide films can be contacted in the freshly sintered (still warm) state over a sufficient period (for example about 0.5 to 24 h) with a solution or suspension of the dye in a suitable organic solvent. This can be accomplished, for example, by immersing the metal oxide-coated substrate into the solution of the dye.

If combinations of different dyes are to be used, they may, for example, be applied successively from one or more solutions or suspensions which comprise one or more of the dyes. It is also possible to use two dyes which are separated by a layer of, for example, CuSCN (on this subject see, for example, Tennakone, K.J., Phys. Chem. B. 2003, 107, 13758). The most convenient method can be determined comparatively easily in the individual case.

In the selection of the dye and of the size of the oxide particles of the n-semiconducting metal oxide, the organic solar cell should be configured such that a maximum amount of light is absorbed. The oxide layers should be structured such that the solid p-type semiconductor can efficiently fill the pores. For instance, smaller particles have greater surface areas and are therefore capable of adsorbing a greater amount of dyes. On the other hand, larger particles generally have larger pores which enable better penetration through the p-conductor.

p-semiconducting organic material

As described above, the at least one DSC or sDSC of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor can comprise in particular at least one p-semiconducting organic material, preferably at least one solid p-semiconducting material, which is also designated hereinafter as p-type semiconductor or p-type conductor. Hereinafter, a description is given of a series of preferred examples of such organic p-type semiconductors which can be used individually or else in any desired combination, for example in a combination of a plurality of layers with a respective p-type semiconductor, and/or in a combination of a plurality of p-type semiconductors in one layer.

In order to prevent recombination of the electrons in the n-semiconducting metal oxide with the solid p-conductor, it is possible to use, between the n-semiconducting metal oxide and the p-type semiconductor, at least one passivating layer which has a passivating material. This layer should be very thin and should as far as possible cover only the as yet uncovered sites of the n-semiconducting metal oxide. The passivation material may, under some circumstances, also be applied to the metal oxide before the dye. Preferred passivation materials are especially one or more of the following substances: Al_2O_3 ; silanes, for example CH_3SiCl_3 ; Al^{3+} ; 4-tert-butylpyridine

(TBP); MgO; GBA (4-guanidinobutyric acid) and similar derivatives; alkyl acids; hexadecylmalonic acid (HDMA).

As described above, in the context of the organic solar cell, preferably one or more solid organic p-type semiconductors are used – alone or else in combination with one or more further p-type semiconductors which are organic or inorganic in nature. In the context of the present invention, a p-type semiconductor is generally understood to mean a material, especially an organic material, which is capable of conducting holes, that is to say positive charge carriers. More particularly, it may be an organic material with an extensive π -electron system which can be oxidized stably at least once, for example to form what is called a free-radical cation. For example, the p-type semiconductor may comprise at least one organic matrix material which has the properties mentioned. Furthermore, the p-type semiconductor can optionally comprise one or a plurality of dopants which intensify the p-semiconducting properties. A significant parameter influencing the selection of the p-type semiconductor is the hole mobility, since this partly determines the hole diffusion length (cf. Kumara, G., Langmuir, 2002, 18, 10493-10495). A comparison of charge carrier mobilities in different spiro compounds can be found, for example, in T. Saragi, Adv. Funct. Mater. 2006, 16, 966-974.

Preferably, in the context of the present invention, organic semiconductors are used (i.e. low molecular weight, oligomeric or polymeric semiconductors or mixtures of such semiconductors). Particular preference is given to p-type semiconductors which can be processed from a liquid phase. Examples here are p-type semiconductors based on polymers such as polythiophene and polyarylamines, or on amorphous, reversibly oxidizable, nonpolymeric organic compounds, such as the spirobifluorenes mentioned at the outset (cf., for example, US 2006/0049397 and the spiro compounds disclosed therein as p-type semiconductors, which are also usable in the context of the present invention). Preference is given to using low molecular weight organic semiconductors, such as the low molecular weight p-type semiconducting materials as disclosed in WO 2012/110924 A1, preferably spiro-MeOTAD, and/or one or more of the p-type semiconducting materials disclosed in Leijtens et al., ACS Nano, VOL. 6, NO. 2, 1455-1462 (2012). Additionally or alternatively, one or more of the p-type semiconducting materials as disclosed in WO 2010/094636 A1 may be used, the full content of which is herewith included by reference. In addition, reference may also be made to the remarks regarding the p-semiconducting materials and dopants from the above description of the prior art.

The p-type semiconductor is preferably producible or produced by applying at least one p-conducting organic material to at least one carrier element, wherein the application is effected for example by deposition from a liquid phase comprising the at least one p-conducting organic material. The deposition can in this case once again be effected, in principle, by any desired deposition process, for example by spin-coating, knife-coating, printing or combinations of the stated and/or other deposition methods.

The organic p-type semiconductor may especially comprise at least one spiro compound and/or especially be selected from: a spiro compound, especially spiro-MeOTAD; a compound with the structural formula:

in which

A¹, A², A³ are each independently optionally substituted aryl groups or heteroaryl groups,

R¹, R², R³ are each independently selected from the group consisting of the substituents -R, -OR, -NR₂, -A⁴-OR and -A⁴-NR₂,

where R is selected from the group consisting of alkyl, aryl and heteroaryl,

and

where A⁴ is an aryl group or heteroaryl group, and

where n at each instance in formula I is independently a value of 0, 1, 2 or 3,

with the proviso that the sum of the individual n values is at least 2 and at least two of the R¹, R² and R³ radicals are -OR and/or -NR₂.

Preferably, A² and A³ are the same; accordingly, the compound of the formula (I) preferably has the following structure (Ia)

- 5 More particularly, as explained above, the p-type semiconductor may thus have at least one low molecular weight organic p-type semiconductor. A low molecular weight material is generally understood to mean a material which is present in monomeric, nonpolymerized or nonoligomerized form. The term "low molecular weight" as used in the present context preferably means that the p-type semiconductor has molecular weights in the range from 100 to 25 000 g/mol. Preferably, the low molecular weight substances have molecular weights of 500 to 2000 g/mol.

In general, in the context of the present invention, p-semiconducting properties are understood to mean the property of materials, especially of organic molecules, to form holes and to transport these holes and/or to pass them on to adjacent molecules. More particularly, stable oxidation of these molecules should be possible. In addition, the low molecular weight organic p-type semiconductors mentioned may especially have an extensive π -electron system. More particularly, the at least one low molecular weight p-type semiconductor may be processable from a solution. The low molecular weight p-type semiconductor may especially comprise at least one triphenylamine. It is particularly preferred when the low molecular weight organic p-type semiconductor comprises at least one spiro compound. A spiro compound is understood to mean polycyclic organic compounds whose rings are joined only at one atom, which is also referred to as the spiro atom. More particularly, the spiro atom may be sp^3 -hybridized, such that the constituents of the spiro compound connected to one another via the spiro atom are, for example, arranged in different planes with respect to one another.

More preferably, the spiro compound has a structure of the following formula:

- 5 where the aryl¹, aryl², aryl³, aryl⁴, aryl⁵, aryl⁶, aryl⁷ and aryl⁸ radicals are each independently selected from substituted aryl radicals and heteroaryl radicals, especially from substituted phenyl radicals, where the aryl radicals and heteroaryl radicals, preferably the phenyl radicals, are each independently substituted, preferably in each case by one or more substituents selected from the group consisting of -O-alkyl, -OH, -F, -Cl, -Br and -I, where alkyl is preferably
 10 methyl, ethyl, propyl or isopropyl. More preferably, the phenyl radicals are each independently substituted, in each case by one or more substituents selected from the group consisting of -O-Me, -OH, -F, -Cl, -Br and -I.

Further preferably, the spiro compound is a compound of the following formula:

15

- where Rʳ, Rˢ, Rᵗ, Rᵁ, Rᵛ, Rʷ, Rˣ and Rʸ are each independently selected from the group consisting of -O-alkyl, -OH, -F, -Cl, -Br and -I, where alkyl is preferably methyl, ethyl, propyl or
 20 isopropyl. More preferably, Rʳ, Rˢ, Rᵗ, Rᵁ, Rᵛ, Rʷ, Rˣ and Rʸ are each independently selected from the group consisting of -O-Me, -OH, -F, -Cl, -Br and -I.

More particularly, the p-type semiconductor may comprise spiro-MeOTAD or consist of spiro-MeOTAD, i.e. a compound of the formula below, commercially available, for example, from Merck KGaA, Darmstadt, Germany:

Alternatively or additionally, it is also possible to use other p-semiconducting compounds, especially low molecular weight and/or oligomeric and/or polymeric p-semiconducting compounds.

10

In an alternative embodiment, the low molecular weight organic p-type semiconductor comprises one or more compounds of the above-mentioned general formula I, for which reference may be made, for example, to PCT application number PCT/EP2010/051826, which will be published after the priority date of the present application. The p-type semiconductor may comprise the at least one compound of the above-mentioned general formula I additionally or alternatively to the spiro compound described above.

15

The term "alkyl" or "alkyl group" or "alkyl radical" as used in the context of the present invention is understood to mean substituted or unsubstituted C₁-C₂₀-alkyl radicals in general. Preference is given to C₁- to C₁₀-alkyl radicals, particular preference to C₁- to C₈-alkyl radicals. The alkyl radicals may be either straight-chain or branched. In addition, the alkyl radicals may be substituted by one or more substituents selected from the group consisting of C₁-C₂₀-alkoxy, halogen, preferably F, and C₆-C₃₀-aryl which may in turn be substituted or unsubstituted.

20

Examples of suitable alkyl groups are methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl and octyl, and also isopropyl, isobutyl, isopentyl, sec-butyl, tert-butyl, neopentyl, 3,3-dimethylbutyl, 2-

25

ethylhexyl, and also derivatives of the alkyl groups mentioned substituted by C₆-C₃₀-aryl, C₁-C₂₀-alkoxy and/or halogen, especially F, for example CF₃.

The term "aryl" or "aryl group" or "aryl radical" as used in the context of the present invention is understood to mean optionally substituted C₆-C₃₀-aryl radicals which are derived from monocyclic, bicyclic, tricyclic or else multicyclic aromatic rings, where the aromatic rings do not comprise any ring heteroatoms. The aryl radical preferably comprises 5- and/or 6-membered aromatic rings. When the aryls are not monocyclic systems, in the case of the term "aryl" for the second ring, the saturated form (perhydro form) or the partly unsaturated form (for example the dihydro form or tetrahydro form), provided the particular forms are known and stable, is also possible. The term "aryl" in the context of the present invention thus comprises, for example, also bicyclic or tricyclic radicals in which either both or all three radicals are aromatic, and also bicyclic or tricyclic radicals in which only one ring is aromatic, and also tricyclic radicals in which two rings are aromatic. Examples of aryl are: phenyl, naphthyl, indanyl, 1,2-dihydronaphthenyl, 1,4-dihydronaphthenyl, fluorenyl, indenyl, anthracenyl, phenanthrenyl or 1,2,3,4-tetrahydronaphthyl. Particular preference is given to C₆-C₁₀-aryl radicals, for example phenyl or naphthyl, very particular preference to C₆-aryl radicals, for example phenyl. In addition, the term "aryl" also comprises ring systems comprising at least two monocyclic, bicyclic or multicyclic aromatic rings joined to one another via single or double bonds. One example is that of biphenyl groups.

The term "heteroaryl" or "heteroaryl group" or "heteroaryl radical" as used in the context of the present invention is understood to mean optionally substituted 5- or 6-membered aromatic rings and multicyclic rings, for example bicyclic and tricyclic compounds having at least one heteroatom in at least one ring. The heteroaryls in the context of the invention preferably comprise 5 to 30 ring atoms. They may be monocyclic, bicyclic or tricyclic, and some can be derived from the afore-mentioned aryl by replacing at least one carbon atom in the aryl base skeleton with a heteroatom. Preferred heteroatoms are N, O and S. The heteroaryl radicals more preferably have 5 to 13 ring atoms. The base skeleton of the heteroaryl radicals is especially preferably selected from systems such as pyridine and five-membered heteroaromatics such as thiophene, pyrrole, imidazole or furan. These base skeletons may optionally be fused to one or two six-membered aromatic radicals. In addition, the term "heteroaryl" also comprises ring systems comprising at least two monocyclic, bicyclic or multicyclic aromatic rings joined to one another via single or double bonds, where at least one ring comprises a heteroatom. When the heteroaryls are not monocyclic systems, in the case of the term "heteroaryl" for at least one ring, the saturated form (perhydro form) or the partly unsaturated form (for example the dihydro form or tetrahydro form), provided the particular forms are known and stable, is also possible. The term "heteroaryl" in the context of the present invention thus comprises, for example, also bicyclic or tricyclic radicals in which either both or all three radicals are aromatic, and also bicyclic or tricyclic radicals in which only one ring is aromatic, and also tricyclic radicals in which two rings are aromatic, where at least one of the rings, i.e. at least one aromatic or one nonaromatic ring has a heteroatom. Suitable fused heteroaromatics are, for example,

carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl. The base skeleton may be substituted at one, more than one or all substitutable positions, suitable substituents being the same as have already been specified under the definition of C₆-C₃₀-aryl. However, the hetaryl radicals are preferably unsubstituted. Suitable hetaryl radicals are, for example, pyridin-2-yl, pyridin-3-yl, pyridin-4-yl, thiophen-2-yl, thiophen-3-yl, pyrrol-2-yl, pyrrol-3-yl, furan-2-yl, furan-3-yl and imidazol-2-yl and the corresponding benzofused radicals, especially carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl.

In the context of the invention the term "optionally substituted" refers to radicals in which at least one hydrogen radical of an alkyl group, aryl group or heteroaryl group has been replaced by a substituent. With regard to the type of this substituent, preference is given to alkyl radicals, for example methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl and octyl, and also isopropyl, isobutyl, isopentyl, sec-butyl, tert-butyl, neopentyl, 3,3-dimethylbutyl and 2-ethylhexyl, aryl radicals, for example C₆-C₁₀-aryl radicals, especially phenyl or naphthyl, most preferably C₆-aryl radicals, for example phenyl, and hetaryl radicals, for example pyridin-2-yl, pyridin-3-yl, pyridin-4-yl, thiophen-2-yl, thiophen-3-yl, pyrrol-2-yl, pyrrol-3-yl, furan-2-yl, furan-3-yl and imidazol-2-yl, and also the corresponding benzofused radicals, especially carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl. Further examples include the following substituents: alkenyl, alkynyl, halogen, hydroxyl.

The degree of substitution here may vary from monosubstitution up to the maximum number of possible substituents.

Preferred compounds of the formula I for use in accordance with the invention are notable in that at least two of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. The at least two radicals here may be only -OR radicals, only -NR₂ radicals, or at least one -OR and at least one -NR₂ radical.

Particularly preferred compounds of the formula I for use in accordance with the invention are notable in that at least four of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. The at least four radicals here may be only -OR radicals, only -NR₂ radicals or a mixture of -OR and -NR₂ radicals.

Very particularly preferred compounds of the formula I for use in accordance with the invention are notable in that all of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. They may be only -OR radicals, only -NR₂ radicals or a mixture of -OR and -NR₂ radicals.

In all cases, the two R in the -NR₂ radicals may be different from one another, but they are preferably the same.

Preferably, A¹, A² and A³ are each independently selected from the group consisting of

76

in which

5

m is an integer from 1 to 18,

R^4 is alkyl, aryl or heteroaryl, where R^4 is preferably an aryl radical, more preferably a phenyl radical,

10

R^5, R^6 are each independently H, alkyl, aryl or heteroaryl,

where the aromatic and heteroaromatic rings of the structures shown may optionally have further substitution. The degree of substitution of the aromatic and heteroaromatic rings here may vary from monosubstitution up to the maximum number of possible substituents.

15

Preferred substituents in the case of further substitution of the aromatic and heteroaromatic rings include the substituents already mentioned above for the one, two or three optionally substituted aromatic or heteroaromatic groups.

20

Preferably, the aromatic and heteroaromatic rings of the structures shown do not have further substitution.

More preferably, A^1, A^2 and A^3 are each independently

25

more preferably

More preferably, the at least one compound of the formula (I) has one of the following structures:

5

ID367

10

ID522

In an alternative embodiment, the organic p-type semiconductor comprises a compound of the type ID322 having the following structure:

The compounds for use in accordance with the invention can be prepared by customary methods of organic synthesis known to those skilled in the art. References to relevant (patent) literature can additionally be found in the synthesis examples adduced below.

Second electrode

a) General remarks

The second electrode may be a bottom electrode facing the substrate or else a top electrode facing away from the substrate. As outlined above, the second electrode may be fully or partially transparent or, else, may be intransparent. As used herein, the term partially transparent refers to the fact that the second electrode may comprise transparent regions and intransparent regions.

In case the second electrode is fully or partially transparent, the second electrode may comprise at least one transparent conductive electrode material, which may be selected from the group consisting of: an inorganic transparent conductive material; an organic transparent conductive material. As an example of an inorganic conductive transparent material, a metal oxide may be used, such as ITO and/or FTO. As an example of an organic transparent conductive material, one or more electrically conductive polymer materials may be used. As used herein, the term "transparent" refers to the actual layer or layer setup of the second electrode. Thus, the transparency may be generated by using thin layers, such as layers having a thickness of less than 100 nm, more preferably less than 50 nm.

One or more materials of the following group of materials may be used: at least one metallic material, preferably a metallic material selected from the group consisting of aluminum, silver, platinum, gold; at least one nonmetallic inorganic material, preferably LiF; at least one organic conductive material, preferably at least one electrically conductive polymer and, more preferably, at least one transparent electrically conductive polymer.

The second electrode may comprise one or more metals in a pure form and/or may comprise one or more metal alloys. The second electrode may further comprise a single layer and/or may comprise a layer setup of two or more layers, wherein, preferably at least one layer is a metal layer comprising one or more metals or metal alloys. As an example, the second electrode may comprise at least one metal selected from the group listed in the preceding paragraph in a pure form and/or as a component of an alloy. As an example, the second electrode may comprise at least one alloy selected from the group consisting of: a molybdenum alloy; a niobium alloy; a neodymium alloy; an aluminum alloy. Most preferably, the second electrode may comprise at least one alloy selected from the group consisting of: MoNb; AlNd; MoNb. As an example, a layer setup comprising two or more layers of two or more of the named alloys may be used, such as a layer setup comprising the following layers: MoNb / AlNd / MoNb. As an example, the following layer thicknesses may be used: MoNb 30nm / AlNd 100 nm / MoNb 30nm. Additionally or alternatively, however, other setups and/or other layer thicknesses may be used.

The second electrode may comprise at least one metal electrode, wherein one or more metals in pure form or as a mixture/alloy, such as especially aluminum or silver may be used.

Additionally or alternatively, nonmetallic materials may be used, such as inorganic materials and/or organic materials, both alone and in combination with metal electrodes. As an example, the use of inorganic/organic mixed electrodes or multilayer electrodes is possible, for example the use of LiF/Al electrodes. Additionally or alternatively, conductive polymers may be used. Thus, the second electrode of the at least one transversal optical sensor and/or the second electrode of the at least one longitudinal optical sensor preferably may comprise one or more conductive polymers.

As an example, one or more electrically conductive polymers may be used, selected from the group consisting of: polyaniline (PANI) and/or its chemical relatives; a polythiophene and/or its chemical relatives, such as poly(3-hexylthiophene) (P3HT) and/or PEDOT:PSS (poly(3,4-ethylenedioxythiophene) poly(styrenesulfonate)). Additionally or alternatively, one or more of the conductive polymers as disclosed in EP2507286 A2, EP2205657 A1 or EP2220141 A1

In addition or alternatively, inorganic conductive materials may be used, such as inorganic conductive carbon materials, such as carbon materials selected from the group consisting of: graphite, graphene, carbon nano-tubes, carbon nano-wires.

In addition, it is also possible to use electrode designs in which the quantum efficiency of the components is increased by virtue of the photons being forced, by means of appropriate reflections, to pass through the absorbing layers at least twice. Such layer structures are also referred to as "concentrators" and are likewise described, for example, in WO 02/101838 (especially pages 23-24).

The second electrode may be identical for the at least one transversal optical sensor and the at least one longitudinal optical sensor. Still, different setups of the second electrode for the transversal optical sensor and the longitudinal optical sensor may be used.

5 b) Second electrode of the transversal sensor device

Preferably, the second electrode for the at least one transversal sensor device is at least partially transparent. As an example, the second electrode of the transversal sensor device may comprise at least one transparent electrode layer which covers a sensor region, preferably a
10 sensor area, of the transversal optical sensor. As outlined above, the at least one transparent electrode layer preferably may comprise at least one layer of an electrically conductive polymer, preferably a transparent electrically conductive polymer.

Additionally, the second electrode of the transversal sensor device may comprise two or more
15 partial electrodes, which, preferably, may be made of one or more metals, such as one or more of the metals and/or metal alloys listed above. As an example, the two or more partial electrodes may form a frame which surrounds the sensor region, preferably the sensor area, of the transversal optical sensor. The frame may have a polygonal shape, such as a rectangular or, preferably, a square shape. Preferably, on each side of the polygon, preferably the rectangle
20 or square, one partial electrodes is provided, such as a partial electrode being formed as a bar fully or partially extending along the side.

The at least one electrically conductive polymer may have an electrical conductivity of at least one order of magnitude below electrical conductivity of the material of the partial electrodes,
25 preferably of at least two orders of magnitude below. The at least one electrically conductive polymer may electrically interconnect the partial electrodes. Thus, as outlined above, the partial electrodes may form a frame surrounding a sensor region, preferably a sensor area, of the transversal optical sensor. The at least one layer of the electrically conductive polymer may form a transparent, electrically conductive layer which fully or partially covers the sensor region
30 and which electrically contacts the partial electrodes. As an example, the partial electrodes may comprise metal strips or metal bars along the sides of a rectangle, wherein an inner region of the rectangle forms the sensor region, wherein the at least one layer of the electrically conductive polymer forms one or more transparent electrode layers fully or partially covering the inner region of the rectangle and electrically contacting the metal strips or bars.

35 In case two or more partial electrodes are used which, preferably, are electrically interconnected by at least one layer of an electrically conductive polymer, each of the partial electrodes may be contacted individually, such as by one or more electrical leads or contact pads. Thus, by electrically contacting the partial electrodes, an electrical current through each of the partial
40 electrodes may be measured individually, such as by using an individual current measurement device and/or by using a sequential measurement scheme for individually detecting the currents through the partial electrodes. The detector, for the purpose of measuring the currents through

the partial electrodes, may provide an appropriate measurement setup comprising one or more current measurement devices.

c) Second electrode of the longitudinal sensor device

Generally, with regard to the at least one second electrode of the at least one longitudinal sensor device, the above-mentioned details regarding the transversal sensor device may apply mutatis mutandis. Again, the second electrode of the at least one longitudinal sensor device preferably is transparent. In case a plurality of longitudinal sensor devices is provided, such as in a stack, preferably all second electrodes of the longitudinal sensor devices are transparent but the second electrode of the last longitudinal sensor device facing away from the object. The second electrode of the last longitudinal sensor device may be transparent or intransparent.

With regard to materials which may be used for the second electrode of the longitudinal sensor device, reference may be made to the above-mentioned materials, which may be selected from metallic materials, nonmetallic inorganic materials and electrically conductive organic materials.

Again, the second electrode of the longitudinal optical sensor or, in case a plurality of longitudinal optical sensors is provided, of at least one of the longitudinal optical sensors may optionally be subdivided into partial electrodes which may be contacted individually. However, since for the purpose of the at least one longitudinal optical sensor generally only one individual longitudinal sensor signal is required per longitudinal optical sensor, the second electrode of the at least one longitudinal optical sensor may as well be designed to provide a single sensor signal and, thus, may provide a single electrode contact only.

The second electrode of the longitudinal optical sensor, again, preferably may comprise one or more layers of an electrically conductive polymer, such as one or more of the polymers mentioned above. The at least one layer of the electrically conductive polymer, which preferably is transparent, may fully or partially cover the sensor region, preferably a sensor area, of the longitudinal optical sensor. In addition, one or more contact pads may be provided which electrically contact the at least one electrically conductive polymer layer. This at least one contact pad for the second electrode of the longitudinal optical sensor preferably may be made of at least one metal, such as at least one of the methods mentioned above, and/or may fully or partially be made of at least one inorganic conductive material, such as one or more transparent conductive oxides, such as one or more of the conductive oxides mentioned above with regard to the first electrode.

Encapsulation

The at least one transversal optical sensor and/or the at least one longitudinal optical sensor may further be encapsulated and/or packaged, in order to provide protection against

environmental influences, such as oxygen and/or humidity. Thereby, an increased long-term stability may be provided.

Therein, each of the optical sensors may be encapsulated individually. Thus, an individual
5 encapsulation may be provided for each of the optical sensors, such as an encapsulation for the transversal optical sensor or each of the transversal optical sensors, and an individual encapsulation for the longitudinal optical sensor or for each of the longitudinal optical sensors. Additionally or alternatively, a plurality of optical sensors may be encapsulated as a group. Thus, an encapsulation may be provided which encapsulates more than one optical sensor,
10 such as a plurality of transversal optical sensors, a plurality of longitudinal optical sensors, or at least one transversal optical sensor and at least one longitudinal optical sensor.

For the purpose of encapsulation, various techniques may be used. Thus, the detector may comprise an airtight housing which protects the optical sensors. Additionally or alternatively,
15 specifically in case organic photodetectors and, more preferably, DSCs or sDSCs are used, an encapsulation by one or more lids interacting with a substrate of the optical sensors may be used. Thus, a lid made of a metal, a ceramic material or a glass material may be glued to a substrate of the optical sensors, wherein a layer setup is located in inner space of the lid. Two or more contact leads for contacting the at least one first electrode and the at least one second
20 electrode may be provided which may be contacted from the outside of the lid.

Various other encapsulation techniques may be used alternatively or in addition. Thus, encapsulation by one or more encapsulation layers may be provided. The at least one encapsulation layer may be deposited on top of a layer setup of the devices. Thus, one or more
25 organic and/or inorganic encapsulation materials such as one or more barrier materials may be used.

Synthesis examples:

30 Syntheses of various compounds which can be used in dye solar cells in the context of the present invention, in particular as p-type semiconductors, are listed by way of example in WO 2012/110924 A1, the content of which is herewith included by reference.

35 Overall, in the context of the present invention, the following embodiments are regarded as particularly preferred:

Embodiment 1: A detector for determining a position of at least one object, comprising:

- 40
- at least one transversal optical sensor, the transversal optical sensor being adapted to determine a transversal position of at least one light beam traveling from the object to the detector, the transversal position being a position in at least one dimension

perpendicular to an optical axis of the detector, the transversal optical sensor being adapted to generate at least one transversal sensor signal;

- at least one longitudinal optical sensor, wherein the longitudinal optical sensor has at least one sensor region, wherein the longitudinal optical sensor is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region by the light beam, wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam in the sensor region;
- at least one evaluation device, wherein the evaluation device is designed to generate at least one item of information on a transversal position of the object by evaluating the transversal sensor signal and to generate at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal.

Embodiment 2: The detector according to the preceding embodiment, wherein the transversal optical sensor is a photo detector having at least one first electrode, at least one second electrode and at least one photovoltaic material, wherein the photovoltaic material is embedded in between the first electrode and the second electrode, wherein the photovoltaic material is adapted to generate electric charges in response to an illumination of the photovoltaic material with light, wherein the second electrode is a split electrode having at least two partial electrodes, wherein the transversal optical sensor has a sensor region, wherein the at least one transversal sensor signal indicates a position of the light beam in the sensor region, preferably a sensor area.

Embodiment 3: The detector according to the preceding embodiment, wherein electrical currents through the partial electrodes are dependent on a position of the light beam in the sensor region.

Embodiment 4: The detector according to the preceding embodiment, wherein the transversal optical sensor is adapted to generate the transversal sensor signal in accordance with the electrical currents through the partial electrodes.

Embodiment 5: The detector according to any of the two preceding embodiments, wherein the detector, preferably the transversal optical sensor and/or the evaluation device, is adapted to derive the information on the transversal position of the object from at least one ratio of the currents through the partial electrodes.

Embodiment 6: The detector according to any of the four preceding embodiments, wherein at least four partial electrodes are provided.

Embodiment 7: The detector according to any of the five preceding embodiments, wherein the photovoltaic material comprises at least one organic photovoltaic material and wherein the transversal optical sensor is an organic photo detector.

Embodiment 8: The detector according to any of the six preceding embodiments, wherein the organic photo detector is a dye-sensitized solar cell.

5 Embodiment 9: The detector according to the preceding embodiment, wherein the dye-sensitized solar cell is a solid dye-sensitized solar cell, comprising a layer setup embedded in between the first electrode and the second electrode, the layer setup comprising at least one n-semiconducting metal oxide, at least one dye, and at least one solid p-semiconducting organic material.

10

Embodiment 10: The detector according to any of the eight preceding embodiments, wherein the first electrode at least partially is made of at least one transparent conductive oxide, wherein the second electrode at least partially is made of an electrically conductive polymer, preferably a transparent electrically conductive polymer.

15

Embodiment 11: The detector according to the preceding embodiment, wherein the conductive polymer is selected from the group consisting of: a poly-3,4-ethylenedioxythiophene (PEDOT), preferably PEDOT being electrically doped with at least one counter ion, more preferably PEDOT doped with sodium polystyrene sulfonate (PEDOT:PSS); a polyaniline (PANI); a polythiophene.

20

Embodiment 12: The detector according to any of the two preceding embodiments, wherein the conductive polymer provides an electric resistivity of 0.1 – 20 k Ω between the partial electrodes, preferably an electric resistivity of 0.5 – 5.0 k Ω and, more preferably, an electric resistivity of 1.0 – 3.0 k Ω .

25

Embodiment 13: The detector according to any of the preceding embodiments, wherein at least one of the transversal optical sensor and the longitudinal optical sensor is a transparent optical sensor.

30

Embodiment 14: The detector according to the preceding embodiment, wherein the light beam passes through the transparent optical sensor before impinging on the other one of the transversal optical sensor and the longitudinal optical sensor.

35 Embodiment 15: The detector according to any one of the preceding embodiments, wherein the detector further comprises at least one imaging device.

Embodiment 16: The detector according to the preceding claim, wherein the detector comprises a stack of optical sensors, the optical sensors comprising the at least one transversal optical sensor and the at least one longitudinal optical sensor, the stack further comprising the imaging device.

40

Embodiment 17: The detector according to the preceding claim, wherein the imaging device is located in a position of the stack furthest away from the object.

Embodiment 18: The detector according to any of the three preceding embodiments, wherein the light beam passes through the at least one longitudinal optical sensor before illuminating the imaging device.

Embodiment 19: The detector according to any of the four preceding embodiments, wherein the imaging device comprises a camera.

Embodiment 20: The detector according to any of the five preceding embodiments, wherein the imaging device comprises at least one of: an inorganic camera; a monochrome camera; a multichrome camera; a full-color camera; a pixelated inorganic chip; a pixelated organic camera; a CCD chip, preferably a multi-color CCD chip or a full-color CCD chip; a CMOS chip; an IR camera; an RGB camera.

Embodiment 21: The detector according to any of the preceding embodiments, wherein the transversal optical sensor and the longitudinal optical sensor at least partially are identical.

Embodiment 22: The detector according to any of the preceding embodiments, wherein the transversal optical sensor and the longitudinal optical sensor at least partially are independent optical sensors.

Embodiment 23: The detector according to any of the preceding embodiments, wherein the transversal optical sensor and the longitudinal optical sensor are stacked along the optical axis such that a light beam travelling along the optical axis both impinges on the transversal optical sensor and on the longitudinal optical sensor.

Embodiment 24: The detector according to the preceding embodiment, wherein the light beam subsequently passes through the transversal optical sensor and the longitudinal optical sensor or vice versa.

Embodiment 25: The detector according to any of the preceding embodiments, wherein the detector furthermore has at least one modulation device for modulating the illumination.

Embodiment 26: The detector according to the preceding embodiment, wherein the detector is designed to detect at least two longitudinal sensor signals in the case of different modulations, in particular at least two sensor signals at respectively different modulation frequencies, wherein the evaluation device is designed to generate the at least one item of information on the longitudinal position of the object by evaluating the at least two longitudinal sensor signals.

Embodiment 27: The detector according to any of the preceding embodiments, wherein the longitudinal optical sensor is furthermore designed in such a way that the longitudinal sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination.

5

Embodiment 28: The detector according to any of the preceding embodiments, wherein the sensor region of the longitudinal optical sensor is exactly one continuous sensor region, wherein the longitudinal sensor signal is a uniform sensor signal for the entire sensor region.

10

Embodiment 29: The detector according to any of the preceding embodiments, wherein the sensor region of the transversal optical sensor and/or the sensor region of the longitudinal optical sensor is or comprises a sensor area, the sensor area being formed by a surface of the respective device, wherein the surface faces towards the object or faces away from the object.

15

Embodiment 30: The detector according to any of the preceding embodiments, wherein the longitudinal sensor signal is selected from the group consisting of a current and a voltage.

20

Embodiment 31: The detector according to any of the preceding embodiments, wherein the transversal sensor signal is selected from the group consisting of a current and a voltage or any signal derived thereof.

25

Embodiment 32: The detector according to any of the preceding embodiments, wherein the longitudinal optical sensor comprises at least one semiconductor detector, in particular an organic semiconductor detector comprising at least one organic material, preferably an organic solar cell and particularly preferably a dye solar cell or dye-sensitized solar cell, in particular a solid dye solar cell or a solid dye-sensitized solar cell.

30

Embodiment 33: The detector according to the preceding embodiment, wherein the longitudinal optical sensor comprises at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid p-semiconducting organic material, and at least one second electrode.

35

Embodiment 34: The detector according to the preceding embodiment, wherein both the first electrode and the second electrode are transparent.

40

Embodiment 35: The detector according to any of the preceding embodiments, wherein the evaluation device is designed to generate the at least one item of information on the longitudinal position of the object from at least one predefined relationship between the geometry of the illumination and a relative positioning of the object with respect to the detector, preferably taking account of a known power of the illumination and optionally taking account of a modulation frequency with which the illumination is modulated.

Embodiment 36: The detector according to any of the preceding embodiments, furthermore comprising at least one transfer device, wherein the transfer device is designed to feed light emerging from the object to the transversal optical sensor and the longitudinal optical sensor.

- 5 Embodiment 37: The detector according to any of the preceding embodiments, furthermore comprising at least one illumination source.

10 Embodiment 38: The detector according to the preceding embodiment, wherein the illumination source is selected from: an illumination source, which is at least partly connected to the object and/or is at least partly identical to the object; an illumination source which is designed to at least partly illuminate the object with a primary radiation, wherein the light beam preferably is generated by a reflection of the primary radiation on the object and/or by light emission by the object itself, stimulated by the primary radiation.

- 15 Embodiment 39: The detector according to any of the preceding embodiments, wherein the detector has a plurality of longitudinal optical sensors, wherein the longitudinal optical sensors are stacked.

20 Embodiment 40: The detector according to the preceding embodiment, wherein the longitudinal optical sensors are stacked along the optical axis.

25 Embodiment 41: The detector according to any of the two preceding embodiments, wherein the longitudinal optical sensors form a longitudinal optical sensor stack, wherein the sensor regions of the longitudinal optical sensors are oriented perpendicular to the optical axis.

Embodiment 42: The detector according to any of the three preceding embodiments, wherein the transversal optical sensor is located on a side of the stacked longitudinal optical sensors facing the object.

30 Embodiment 43: The detector according to any of the four preceding embodiments, wherein the longitudinal optical sensors are arranged such that a light beam from the object illuminates all longitudinal optical sensors, preferably sequentially, wherein at least one longitudinal sensor signal is generated by each longitudinal optical sensor.

35 Embodiment 44: The detector according to any of the five preceding embodiments, wherein a last longitudinal optical sensor is arranged in a manner that the light beam first illuminates all other longitudinal optical sensors apart from the last longitudinal optical sensor, until the light beam finally illuminates the last longitudinal optical sensor.

40 Embodiment 45: The detector according to the preceding embodiment, wherein the last longitudinal optical sensor is intransparent with respect to the light beam.

Embodiment 46: The detector according to any of the seven preceding embodiments, wherein at least two of the longitudinal optical sensors have a differing spectral sensitivities.

Embodiment 47: The detector according to the preceding embodiment, wherein the differing spectral sensitivities are arranged over a spectral range allowing each of the at least two of the longitudinal optical sensors to be sensitive to a specific color.

Embodiment 48: The detector according to the preceding embodiment, wherein the longitudinal optical sensors comprise at least one first longitudinal optical sensor absorbing light in a first spectral range, wherein the longitudinal optical sensors further comprise at least one second longitudinal optical sensor absorbing light in a second spectral range being different from the first spectral range, wherein the longitudinal optical sensors further comprise at least one third longitudinal optical sensor absorbing light in a third spectral range which includes both the first spectral range and the second spectral range.

Embodiment 49: The detector according to any of the six preceding embodiments, wherein the evaluation device is adapted to normalize the longitudinal sensor signals and to generate the information on the longitudinal position of the object independent from an intensity of the light beam.

Embodiment 50: The detector according to any of the seven preceding embodiments, wherein the evaluation device is adapted to recognize whether the light beam widens or narrows, by comparing the longitudinal sensor signals of different longitudinal sensors.

Embodiment 51: The detector according to any of the preceding embodiments, wherein the stack of at least two optical sensors is partially or fully be immersed in an oil, in a liquid and/or in a solid material.

Embodiment 52: The detector according to the preceding embodiment, wherein the oil, the liquid, and/or the solid material are transparent at least over a part of the ultraviolet, visible, and/or infrared spectral range.

Embodiment 53: The detector according to any of the two preceding embodiments, wherein the solid material is generable by using at least one curable substance and treating the curable substance with a treatment, by which treatment the curable substance is cured into the solid material.

Embodiment 54: The detector according to any of the three preceding embodiments, wherein a region between the at least two optical sensors is partially or fully filled with a substance.

Embodiment 55: The detector according to the preceding embodiment, wherein the substance exhibits a refractive index differing from that of the optical sensors adjoining to the substance on one or both sides of the region.

- 5 Embodiment 56: The detector according to any of the preceding embodiments, wherein the at least one transversal optical sensor and/or the at least one longitudinal optical sensor uses at least two transparent substrates.

- 10 Embodiment 57: The detector according to the preceding embodiment, wherein the substrates exhibit identical properties.

Embodiment 58: The detector according to any of the two preceding embodiments, wherein the substrates differ from each other with regard to a geometrical quantity and/or to a material quantity related to the substrates.

- 15 Embodiment 59: The detector according to the preceding embodiment, wherein the substrates differ from each other by the thickness.

- 20 Embodiment 60: The detector according to any of the two preceding embodiments, wherein the substrates differ from each other by shape.

- 25 Embodiment 61: The detector according to the preceding embodiment, wherein the shape is selected from the group comprising a planar, a planar-convex, a planar-concave, a biconvex, a biconcave or any other form employed for optical purposes.

Embodiment 62: The detector according to any of the six preceding embodiments, wherein the substrates are rigid or flexible.

- 30 Embodiment 63: The detector according to any of the seven preceding embodiments, wherein the substrates are covered or coated.

Embodiment 63: The detector according to any of the eight preceding embodiments, wherein the substrate is shaped in a manner that it exhibits a mirror effect.

- 35 Embodiment 64: The detector according to the preceding embodiment, wherein the substrate is shaped in a manner that it exhibits the effect of a dichroic mirror.

- 40 Embodiment 65: The detector according to any of the preceding embodiments, wherein the evaluation device is adapted to generate the at least one item of information on the longitudinal position of the object by determining a diameter of the light beam from the at least one longitudinal sensor signal.

Embodiment 66: The detector according to the preceding embodiment, wherein the evaluation device is adapted to compare the diameter of the light beam with known beam properties of the light beam in order to determine the at least one item of information on the longitudinal position of the object, preferably from a known dependency of a beam diameter of the light beam on at least one propagation coordinate in a direction of propagation of the light beam and/or from a known Gaussian profile of the light beam.

Embodiment 67: The detector according to any of the preceding embodiments, wherein the detector comprises an optically sensitive element.

Embodiment 68: The detector according to the preceding embodiment, wherein the optically sensitive element is located between the transfer device and the optical sensor.

Embodiment 69: The detector according to any of the two preceding embodiments, wherein the optically sensitive element comprises a wavelength-sensitive element, a phase-sensitive element, and/or a polarization-sensitive element.

Embodiment 70: The detector according to the preceding embodiment, wherein the wavelength-sensitive element comprises one or more of a prism, a grating, a dichroitic mirror, a color wheel, or a color drum.

Embodiment 71: The detector according to the preceding embodiment, wherein the color wheel comprises a sequential color recapture wheel.

Embodiment 72: The detector according to any of the two preceding embodiments, wherein the color wheel or the color drum comprises two or more of at least one red, green, blue, white, cyan, yellow, or magenta segment.

Embodiment 73: The detector according to embodiment 54, wherein the polarization-sensitive element comprises a filter wheel using an elliptically polarizing filter.

Embodiment 74: The detector according to the preceding embodiment, wherein the polarization-sensitive element comprises a filter wheel using a circular polarizing filter.

Embodiment 75: The detector according to any of the two preceding embodiments, wherein the optically sensitive element comprises at least two wheels, at least one first wheel and at least one second wheel, wherein the first wheel constitutes a color wheel and wherein the second wheel constitutes an elliptically polarizing filter.

Embodiment 76: An arrangement comprising at least two detectors according to any of the preceding embodiments.

Embodiment 77: An arrangement according to the preceding embodiment, wherein the at least two detectors have identical optical properties.

5 Embodiment 78: The arrangement according to any of the two preceding embodiments, wherein the arrangement further comprises at least one illumination source.

10 Embodiment 79: A human-machine interface for exchanging at least one item of information between a user and a machine, in particular for inputting control commands, wherein the human-machine interface comprises at least one detector according to any of the preceding
embodiments relating to a detector, wherein the human-machine interface is designed to generate at least one item of geometrical information of the user by means of the detector wherein the human-machine interface is designed to assign to the geometrical information at least one item of information, in particular at least one control command.

15 Embodiment 80: The human-machine interface according to the preceding embodiment, wherein the at least one item of geometrical information of the user is selected from the group consisting of: a position of a body of the user; a position of at least one body part of the user; an orientation of a body of the user; an orientation of at least one body part of the user.

20 Embodiment 81: The human-machine interface according to any of the two preceding embodiments, wherein the human-machine interface further comprises at least one beacon device connectable to the user, wherein the human-machine interface is adapted such that the detector may generate an information on the position of the at least one beacon device.

25 Embodiment 82: The human-machine interface according to the preceding embodiment, wherein the beacon device is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user.

30 Embodiment 83: The human-machine interface according to the preceding embodiment, wherein the beacon device comprises at least one illumination source adapted to generate at least one light beam to be transmitted to the detector.

35 Embodiment 84: The human-machine interface according to any of the two preceding embodiments, wherein the beacon device comprises at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

40 Embodiment 85: The human-machine interface according to any of the three preceding embodiments, wherein the beacon device comprises at least one of: a garment to be worn by the user, preferably a garment selected from the group consisting of a glove, a jacket, a hat, shoes, trousers and a suit; a stick that may be held by hand; a bat; a club; a racket; a cane; a toy, such as a toy gun.

Embodiment 86: An entertainment device for carrying out at least one entertainment function, in particular a game, wherein the entertainment device comprises at least one human-machine interface according to any of the preceding embodiments referring to a human-machine interface, wherein the entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface, wherein the entertainment device is designed to vary the entertainment function in accordance with the information.

Embodiment 87: A tracking system for tracking the position of at least one movable object, the tracking system comprising at least one detector according to any of the preceding embodiments referring to a detector, the tracking system further comprising at least one track controller, wherein the track controller is adapted to track a series of positions of the object, each position comprising at least one item of information on a transversal position of the object at a specific point in time and at least one item of information on a longitudinal position of the object at a specific point in time.

Embodiment 88: The tracking system according to the preceding embodiment, wherein the tracking system further comprises at least one beacon device connectable to the object, wherein the tracking system is adapted such that the detector may generate an information on the position of the object of the at least one beacon device.

Embodiment 89: The tracking system according to the preceding embodiment, wherein the beacon device comprises at least one illumination source adapted to generate at least one light beam to be transmitted to the detector.

Embodiment 90: The tracking system according to any of the two preceding embodiments, wherein the beacon device comprises at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

Embodiment 91: The tracking system according to any of the preceding embodiments referring to a tracking system, wherein the track controller is adapted to initiate at least one action in accordance with an actual position of the object.

Embodiment 92: The tracking system according to the preceding embodiment, wherein the action is selected from the group consisting of: a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.

Embodiment 93: A camera for imaging at least one object, the camera comprising at least one detector according to any one of the preceding embodiments referring to a detector.

Embodiment 94: A method for determining a position of at least one object, in particular using a detector according to any of the preceding embodiments relating to a detector,

- wherein at least one transversal optical sensor of a detector is used, wherein the transversal optical sensor determines a transversal position of at least one light beam traveling from the object to the detector, the transversal position being a position in at least one dimension perpendicular to an optical axis of the detector, wherein the transversal optical sensor generates at least one transversal sensor signal;
- wherein at least one longitudinal optical sensor of the detector is used, wherein the longitudinal optical sensor has at least one sensor region, wherein the longitudinal optical sensor generates at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region by the light beam, wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam in the sensor region;
- wherein at least one evaluation device is used, wherein the evaluation device generates at least one item of information on a transversal position of the object by evaluating the transversal sensor signal and wherein the evaluation device further generates at least one item of information on a longitudinal position of the object by evaluating the longitudinal sensor signal.

Embodiment 95: The use of a detector according to any of the preceding embodiments relating to a detector, for a purpose of use, selected from the group consisting of: a distance measurement, in particular in traffic technology; a position measurement, in particular in traffic technology; an entertainment application; a security application; a human-machine interface application; a tracking application; a photography application; an imaging application or camera application; a mapping application for generating maps of at least one space.

Brief description of the figures

Further optional details and features of the invention are evident from the description of preferred exemplary embodiments which follows in conjunction with the dependent claims. In this context, the particular features may be implemented alone or with several in combination. The invention is not restricted to the exemplary embodiments. The exemplary embodiments are shown schematically in the figures. Identical reference numerals in the individual figures refer to identical elements or elements with identical function, or elements which correspond to one another with regard to their functions.

Specifically, in the figures:

Figure 1A shows an exemplary embodiment of a detector according to the present invention;

- Figure 1B shows a further exemplary embodiment of a detector according to the present invention;
- 5 Figure 1C shows a further exemplary embodiment of a detector according to the present invention;
- Figure 2A and 2B show different views of an embodiment of a transversal detector which may be used in the detector of the present invention;
- 10 Figures 3A to 3D show principles of generating transversal sensor signals and deriving information on a transversal position of an object;
- Figures 4A to 4C show different views of embodiments of a longitudinal optical sensor which may be used in the detector according to the present invention;
- 15 Figures 5A to 5E show the principle of generating longitudinal sensor signals and deriving information on a longitudinal position of an object; and
- 20 Figure 6 shows a schematic embodiment of a human-machine interface and of an entertainment device according to the present invention.

Exemplary embodiments

25 Detector

Figure 1A illustrates, in a highly schematic illustration, an exemplary embodiment of a detector 110 according to the invention, for determining a position of at least one object 112. The detector 110 preferably may form a camera 111 or may be part of a camera 111. Other
30 embodiments are feasible.

The detector 110 comprises a plurality of optical sensors 114, which, in the specific embodiment, are all stacked along an optical axis 116 of the detector 110. Specifically, the optical axis 116 may be an axis of symmetry and/or rotation of the setup of the optical sensors
35 114. The optical sensors 114 may be located inside a housing 118 of the detector 110. Further, at least one transfer device 120 may be comprised, such as one or more optical systems, preferably comprising one or more lenses 122. An opening 124 in the housing 118, which, preferably, is located concentrically with regard to the optical axis 116, preferably defines a direction of view 126 of the detector 110. A coordinate system 128 may be defined, in which a
40 direction parallel or antiparallel to the optical axis 116 is defined as a longitudinal direction, whereas directions perpendicular to the optical axis 116 may be defined as transversal directions. In the coordinate system 128, symbolically depicted in Fig. 1A, a longitudinal

direction is denoted by z and transversal directions are denoted by x and y, respectively. Other types of coordinate systems 128 are feasible.

The optical sensors 114 comprise at least one transversal optical sensor 130 and, in this embodiment, a plurality of longitudinal optical sensors 132. The longitudinal optical sensors 132 form a longitudinal optical sensor stack 134. In the embodiment shown in Fig. 1A, five longitudinal sensors 132 are depicted. It shall be noted, however, that embodiments having a different number of longitudinal optical sensors 132 are feasible.

The transversal optical sensor 132 comprises a sensor region 136, which, preferably, is transparent to a light beam 138 travelling from the object 112 to the detector 110. The transversal optical sensor 130 is adapted to determine a transversal position of the light beam 138 in one or more transversal directions, such as in direction x and/or in direction y. Therein, embodiments are feasible in which a transversal position in only one transversal direction is determined, embodiments in which transversal positions in more than one transversal direction are determined by one and the same transversal optical sensor 130, and embodiments in which a transversal position in a first transversal direction is determined by a first transversal optical sensor and wherein at least one further transversal position in at least one further transversal direction is determined by at least one further transversal optical sensor.

The at least one transversal optical sensor 130 is adapted to generate at least one transversal sensor signal. This transversal sensor signal may be transmitted by one or more transversal signal leads 140 to at least one evaluation device 142 of the detector 110, which will be explained in further detail below.

The longitudinal optical sensors 132 each comprise at least one sensor region 136, too. Preferably, one, more or all of the longitudinal optical sensors 132 are transparent, but the last longitudinal optical sensor 144 of the longitudinal optical sensor stack 134, i.e. the longitudinal optical sensor 132 on the side of the stack 134 facing away from the object 112. This last longitudinal sensor 144 may fully or partially be intransparent.

Each of the longitudinal optical sensors 132 is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the respective sensor region 136 by the light beam 138. The longitudinal sensor signals, given the same total power of the illumination, is dependent on a beam cross-section of the light beam 138 in the respective sensor region 136, as will be outlined in further detail below. Via one or more longitudinal signal leads 146, the longitudinal sensor signals may be transmitted to the evaluation device 142. As will be outlined in further detail below, the evaluation device may be designed to generate at least one item of information on at least one transversal position of the object 112 by evaluating the at least one transversal sensor signal and to generate at least one item of information on at least one longitudinal position of the object 112 by evaluating the longitudinal sensor signal. For this purpose, the evaluation device 142 may comprise one or more electronic devices and/or

one or more software components, in order to evaluate the sensor signals, which is symbolically denoted by transversal evaluation unit 148 (denoted by "xy") and longitudinal evaluation unit 150 (denoted by "z"). By combining results derived by these evolution units 148, 150, a position information 152, preferably a three-dimensional position information, may be generated
5 (denoted by "x, y, z").

The evaluation device 142 may be part of a data processing device 154 and/or may comprise one or more data processing devices 154. The evaluation device 142 may be fully or partially integrated into the housing 118 and/or may fully or partially be embodied as a separate device
10 which is electrically connected in a wireless or wire-bound fashion to the optical sensors 114. The evaluation device 142 may further comprise one or more additional components, such as one or more electronic hardware components and/or one or more software components, such as one or more measurement units (not depicted in Fig. 1A) and/or one or more transformation units 156. Symbolically, in Fig. 1A, one optional transformation unit 156 is depicted which may
15 be adapted to transform at least two transversal sensor signals into a common signal or common information.

In the following, embodiments of the transversal optical sensor 130 and the at least one longitudinal optical sensor 132 are disclosed. It shall be noted, however, that other
20 embodiments are feasible. Thus, in the embodiments disclosed hereinafter, the optical sensors 114 are all designed as solid dye-sensitized solar cells (sDSCs). It shall be noted, however, that other embodiments are feasible.

Fig. 1B illustrates, in a highly schematic illustration, a further exemplary embodiment of the detector 110 according to the present invention, for determining a position of the at least one object 112. In this particular embodiment, the detector 110 may comprise one or more
25 illumination sources 192, which may include an ambient light source and/or an artificial light source, and/or may comprise one or more reflective elements which may, for example, be connected to the object 112 for reflecting one or more primary light beams 206, as indicated in Fig. 1B. In addition or alternatively, the light beam 138 which emerges from the object 112 can
30 fully or partially be generated by the object 112 itself, for example in the form of a luminescent radiation.

The optical sensors 114 comprise at least one transversal optical sensor 130 and, in this
35 embodiment, a plurality of longitudinal optical sensors 132. The longitudinal optical sensors 132 form a longitudinal optical sensor stack 134. In the embodiment shown in Fig. 1B, five longitudinal optical sensors 132 are depicted, wherein the last longitudinal optical sensor 144 comprises a single longitudinal optical sensor 132 out of the plurality of the longitudinal optical sensors 132 within the longitudinal optical sensor stack 134 which faces away from the object
40 112. In this embodiment, it is particularly preferred to arrange the last longitudinal optical sensor 144 in the longitudinal optical sensor stack 134 in a manner that a light beam 138 first travels

through the plurality of the longitudinal optical sensors 132 within the longitudinal optical sensor stack 134 until it impinges the last longitudinal optical sensor 144.

The last longitudinal optical sensor 144 may be configured in various ways. Thus, the last longitudinal optical sensor 144 can for example be part of the detector 110 within the detector housing 118. Alternatively, the last longitudinal optical sensor 144 may be arranged outside the detector housing 118. It shall be emphasized that embodiments having a different number of longitudinal optical sensors 132 within the longitudinal optical sensor stack 134 are feasible.

Whereas the plurality of the longitudinal optical sensors 132 within the longitudinal optical sensor stack 134 with the exception of the last longitudinal optical sensor 144 preferably are at least partially transparent, particularly to enabling a high relative intensity at each of these longitudinal optical sensors 132, the last longitudinal optical sensor 144 may either be transparent or intransparent. In case the last longitudinal optical sensor 144 is transparent, it may be feasible to further place an additional optical sensor behind the longitudinal optical sensor stack 134, such as a separate imaging device 157 in a manner that a light beam 138 first travels through the plurality of the longitudinal optical sensors 132 including the last longitudinal optical sensor 144 until it impinges on the imaging device 157.

The imaging device 157 may be configured in various ways. Thus, the imaging device 157 can for example be part of the detector 110 within the detector housing 118. Alternatively, the imaging device 157 may be separately located outside the detector housing 118. The imaging device 157 may be fully or partially transparent or intransparent. The imaging device 157 may be or may comprise an organic imaging device or an inorganic imaging device. Preferably, the imaging device 157 may comprise at least one matrix of pixels, wherein the matrix of pixels is particularly selected from the group consisting of: an inorganic semiconductor sensor device such as a CCD chip and/or a CMOS chip; an organic semiconductor sensor device. The imaging device signal may be transmitted by one or more imaging device signal leads 159 to at least one evaluation device 142 of the detector 110, which will be explained in further detail below.

In a further preferred embodiment, at least two of the longitudinal optical sensors 132 exhibit a differing spectral sensitivity. Preferably, a last longitudinal optical sensor 144, which preferably is intransparent, is configured to absorb all over the spectral ranges of the at least two of the longitudinal optical sensors have the differing spectral sensitivity. By way of example, the differing spectral sensitivity of at least two of the longitudinal optical sensors 132 varies over spectral range in a manner that the at least two of the longitudinal optical sensors 132 are sensitive to a specific color whereas the intransparent last longitudinal optical sensor 144 is adapted to be sensitive to all colors of the visible spectra range. In a specific embodiment, the longitudinal optical sensors 132 with the exception of the last longitudinal optical sensor 144 are each sensitive to a different specific color with little overlap. This feature particularly allows reliably acquiring depth information for a colored object 112 irrespective of the specific color of

the object 112, for which information at least two of the longitudinal optical sensors 132 are required, as described above. This feature is realized by the fact that for each color, absorption of the light beam 118 always occurs at least in two of the longitudinal optical sensors 132, i.e. in the one of the longitudinal optical sensor 132 which is sensitive to the specific color of the object 112, as well as in the last longitudinal optical sensor 144 being sensitive to all colors.

With respect to the other features as presented in an exemplary fashion in Fig. 1B, reference is made to the above description of Fig. 1A.

A further exemplary embodiment of the detector 110 according to the present invention is shown in Fig. 1C in a highly schematic manner. In this particular embodiment, the detector 110 may comprise one or more optically sensitive elements 161 which may particularly be placed along the optical axis 116 of the detector 110. As depicted herein, the optically sensitive element 161 may preferably be located between the transfer device 120, which here comprises one lens 122, and the optical sensor 114, which, in this embodiment, comprises at least one transversal optical sensor 130 and a plurality of longitudinal optical sensors 132 forming a longitudinal optical sensor stack 134. The optically sensitive element 161 may be configured in a number of ways, such as a wavelength-sensitive element, a phase-sensitive element, or a polarization-sensitive element.

As a non-limiting example, a wavelength-sensitive element comprising a color wheel 163 may be employed here as the optically sensitive element 161. Alternative wavelength-sensitive elements may comprise one or more of a prism, a grating, and/or a dichroitic mirror. The color-wheel 163 may especially comprise a circle around which at least two, preferably two to eight, separate segments are arranged which may differ from each other by their optical effect, particularly a grade of transmission, to the impinging light beam 138. Herein, the separate segments may each act as a filter which may allow determining a contribution of the colors red (R), green (G), and blue (B), also designated as "RGB color wheel". Alternatively, the color wheel 163 commonly designated as a "RGB-W color wheel" and additionally comprising a white (W) segment may be employed. As a further alternative, the color wheel 163 may comprise clear or transparent segments which may be used to increase luminous efficiency. Furthermore, the color wheel 163 may, alternatively or additionally, comprise one or more of the colors cyan, yellow, and magenta. A further alternative may comprise a so-called "color drum", wherein the segments are arranged on the inner surface of a drum where the incident light beam may be directed through in order to impinge an optical sensor.

Moreover, a sequential color recapture wheel (SCR wheel) may be generated from RGB dichroic coatings arranged in an Archimedes spiral pattern. Herein, the Archimedes spiral may exhibit the property that the boundaries between two segments may move at a constant speed in radial direction. Furthermore, it may be possible to include also here white or clear segments. Further examples for rotating color wheels, such as known from video beamer devices, and for color drums may be found under the address www.hcinema.de/farbrad.htm.

With respect to the other features as presented in an exemplary fashion in Fig. 1C, reference is made to the above descriptions concerning Figs. 1A and/or 1B.

5 In Figs. 2A and 2B, different views of a potential embodiment of a transversal optical sensor 130 are depicted. Therein, Fig. 2A shows a top-view on a layer setup of the transversal optical sensor 130, whereas Fig. 2B shows a partial cross-sectional view of the layer setup in a schematic setup. For alternative embodiments of the layer setup, reference may be made to the disclosure above.

10 The transversal optical sensor 130 comprises a transparent substrate 158, such as a substrate made of glass and/or a transparent plastic material. The setup further comprises a first electrode 160, an optical blocking layer 162, at least one n-semiconducting metal oxide 164, sensitized with at least one dye 166, at least one p-semiconducting organic material 168 and at
15 least one second electrode 170. These elements are depicted in Fig. 2B. The setup may further comprise at least one encapsulation 172 which is not depicted in Fig. 2B and which is symbolically depicted in the top-view of Fig. 2A, which may cover a sensor region 136 of the transversal optical sensor 130.

20 As an exemplary embodiment, the substrate 158 may be made of glass, the first electrode 160 may fully or partially be made of fluorine-doped tin oxide (FTO), the blocking layer 162 may be made of dense titanium dioxide (TiO₂), the n-semiconducting metal oxide 164 may be made of nonporous titanium dioxide, the p-semiconducting organic material 168 may be made of spiro-MiOTAD, and the second electrode 170 may comprise PEDOT:PSS. Further, dye ID504, as
25 e.g. disclosed in WO 2012/110924 A1, may be used. Other embodiments are feasible.

As depicted in Figs. 2A and 2B, the first electrode 160 may be a large-area electrode, which may be contacted by a single electrode contact 174. As depicted in the top-view in Fig. 2A, the electrode contacts 174 of the first electrode 160 may be located in corners of the transversal
30 optical sensor 130. By providing more than one electrode contact 174, a redundancy may be generated, and resistive losses over the first electrode 160 might be eliminated, thereby generating a common signal for the first electrode 160.

Contrarily, the second electrode 170 comprises at least two partial electrodes 176. As can be
35 seen in the top-view in Fig. 2A, the second electrode 170 may comprise at least two partial electrodes 178 for an x-direction, and at least two partial electrodes 180 for a y-direction via contact leads 182, these partial electrodes 176 may be contacted electrically through the encapsulation 172.

40 The partial electrodes 176, in this specific embodiment, form a frame which surrounds the sensor region 136. As an example, a rectangular or, more preferably, a square frame may be formed. By using appropriate current measurement devices, electrode currents through the

partial electrodes 176 may be determined individually, such as by current measurement devices implemented into the evaluation device 142. By comparing e.g. electrode currents through the two single x-partial electrodes 178, and by comparing the electrode currents through the individual y-partial electrodes 180, x- and y-coordinates of a light spot 184 generated by the light beam 138 in the sensor region 136 may be determined, as for the outlined with respect to Figs. 3A to 3D below.

In Figs. 3A to 3D, two different situations of a positioning of the object 112 are depicted. Thus, Fig. 3A and Fig. 3B show a situation in which the object 112 is located on the optical axis 116 of the detector 110. Therein, Fig. 3A shows a side-view and Fig. 3B shows a top-view onto the sensor region 136 of the transversal optical sensor 130. The longitudinal optical sensors 132 are not depicted in this setup.

In Fig. 3C and 3D, the setup of Figs. 3A and 3B is depicted in analogous views with the object 112 shifted in a transversal direction, to an off-axis position.

It shall be noted that, in Figs. 3A and 3C, the object 112 is depicted as the source of one or more light beams 138. As will be outlined in further detail below, specifically with respect the embodiment in Fig. 6, the detector 110 may as well comprise one or more illumination sources which may be connected to the object 112 and, thus, which may emit the light beams 138, and/or which might be adapted to illuminate the object 112 and, by the object 112 reflecting primary light beams, generate the light beams 138 by reflection and/or diffusion.

According to well-known imaging equations, the object 112 is imaged onto the sensor region 136 of the transversal optical sensor 130, thereby generating an image 186 of the object 112 on the sensor region 136, which, in the following, will be considered a light spot 184 and/or a plurality of light spots 184.

As can be seen in the partial images 3B and 3D, the light spot 184 on the sensor region 136 will lead, by generating charges in the layer setup of the sDSC, electrode currents, which, in each case, are denoted by i_1 to i_4 . Therein, electrode currents i_1, i_2 denote electrode currents through partial electrodes 180 in y-direction and electrode currents i_3, i_4 denote electrode currents through partial electrodes 178 in x-direction. These electrode currents may be measured by one or more appropriate electrode measurement devices simultaneously or sequentially. By evaluating these electrode currents, x- and y-coordinates may be determined. Thus, the following equations may be used:

$$x_0 = f\left(\frac{i_3 - i_4}{i_3 + i_4}\right) \text{ and } y_0 = f\left(\frac{i_1 - i_2}{i_1 + i_2}\right).$$

Therein, f might be an arbitrary known function, such as a simple multiplication of the quotient of the currents with a known stretch factor and/or an addition of an offset. Thus, generally, the

electrode currents i_1 to i_4 might form transversal sensor signals generated by the transversal optical sensor 130, whereas the evaluation device 142 might be adapted to generate information on a transversal position, such as at least one x-coordinate and/or at least one y-coordinate, by transforming the transversal sensor signals by using a predetermined or determinable transformation algorithm and/or a known relationship.

In Figs. 4A to 4C, various views of longitudinal optical sensors 132 are shown. Therein, Fig. 4A shows a cross-sectional view of a potential layer setup, and Figs. 4B and 4C show top-view of two embodiments of potential longitudinal optical sensors 132. Therein, Fig. 4C shows a potential embodiment of the last longitudinal optical sensor 144, wherein Fig. 4B shows potential embodiments of the remaining longitudinal optical sensors 132 of the longitudinal optical sensor stack 134. Thus, the embodiment in Fig. 4B may form a transparent longitudinal optical sensor 132, whereas the embodiment in Fig. 4C may be an intransparent longitudinal optical sensor 132. Other embodiments are feasible. Thus, the last longitudinal optical sensor 144, alternatively, might also be embodied as a transparent longitudinal optical sensor 132.

As can be seen in the schematic cross-sectional view in Fig. 4A, the longitudinal optical sensor 132 again, might be embodied as an organic photo-detector, preferably as an sDSC. Thus, similarly to the setup of Fig. 2B, a layer setup using a substrate 158, a first electrode 160, a blocking layer 162, an n-semiconducting metal oxide 164 being sensitized with a dye 166, a p-semiconducting organic material 168 and a second electrode 170 may be used. Additionally, an encapsulation 172 may be provided. For potential materials of the layers, reference may be made to Fig. 2B above. Additionally or alternatively, other types of materials may be used.

It shall be noted that, in Fig. 2B, an illumination from the top is symbolically depicted, i.e. an illumination by the light beam 138 from the side of the second electrode 170. Alternatively, an illumination from the bottom, i.e. from the side of the substrate 158 and through the substrate 158, may be used. The same holds true for the setup of Fig. 4A.

However, as depicted in Fig. 4A, in a preferred orientation of the longitudinal optical sensor 132, an illumination by the light beam 138 preferably takes place from the bottom, i.e. through the transparent substrate 158. This is due to the fact that the first electrode 160 may easily be embodied as a transparent electrode, such as by using a transparent conductive oxide, such as FTO. The second electrode 170, as will be outlined in further detail below may either be transparent or, specifically, for the last longitudinal optical sensor 144, intransparent.

In Fig. 4B and Fig. 4C, different setups of the second electrode 170 are depicted. Therein, in Fig. 4B, corresponding to the cross-sectional view of Fig. 4A, the first electrode 160 may be contacted by one or more electrode contacts 174, which, as an example, may comprise one or more metal pads, similar to the setup in Fig. 2B. These electrode contacts 174 may be located in the corners of the substrate 158. Other embodiments are feasible.

The second electrode 170, however, in the setup of Fig. 4B may comprise one or more layers of a transparent electrically conductive polymer 188. As an example, similar to the setup of Figs. 2A and 2B, PEDOT:PSS may be used. Further, one or more top contacts 190 may be provided, which may be made of a metallic material, such as aluminum and/or silver. By using one or more contact leads 182, leading through the encapsulation 172, this top contact 190 may be electrically contacted.

In the exemplary embodiment shown in Fig. 4B, the top contact 190 forms a closed opened frame surrounding the sensor region 136. Thus, as opposed to the partial electrodes 176 in Figs. 2A and 2B, only one top contact 190 is required. However, the longitudinal optical sensor 132 and the transversal optical sensor 130 may be combined in one single device, such as by providing partial electrodes in the setup of Figs. 4A to 4C. Thus, in addition to the FiP effect which will be outlined in further detail below, transversal sensor signals may be generated with the longitudinal optical sensor 132. Thereby, a combined transversal and longitudinal optical sensor may be provided.

The use of the transparent electrically conductive polymer 188 allows for an embodiment of the longitudinal optical sensor 132 in which both the first electrode 160 and the second electrode 170 are at least partially transparent. The same, preferably, holds true for the transversal optical sensor 130. In Fig. 4C, however, a setup of the longitudinal optical sensor 132 is disclosed which uses an intransparent second electrode 170. Thus, as an example, the second electrode 170 may be embodied by using one or more metal layers, such as aluminum and/or silver, instead of or in addition to the at least one electrically conductive polymer 188. Thus, as an example, the electrically conductive polymer 188 may be replaced or may be reinforced by one or more metal layers which, preferably, may cover the full sensor region 136.

In Figs. 5A to 5E, the above-mentioned FiP effect shall be explained. Therein, Fig. 5A shows a side-view of a part of a detector 110, in a plain parallel to the optical axis 116, similar to the setup in Figs. 1, 3A and 3C. Of the detector 110, only the longitudinal optical sensors 132 and the transfer device 120 are depicted. Not shown is at least one transversal optical sensor 130. This transversal optical sensor 130 may be embodied as a separate optical sensor 114 and/or may be combined with one or more of the longitudinal optical sensors 132.

Again, the measurement starts with an emission and/or reflection of one or more light beams 138 by at least one object 112. The object 112 may comprise an illumination source 192, which may be considered as a part of the detector 110. Additionally or alternatively, a separate illumination source 192 may be used.

Due to a characteristic of the light beam 138 itself and/or due to beam shaping characteristics of the transfer device 120, preferably of the at least one lens 122, the beam properties of the light beam 138 in the region of the longitudinal optical sensors 132 at least partially are known. Thus,

as depicted in Fig. 5A, one or more focal points 194 might occur. In the focal point 194, a beam waist or a cross-section of the light beam 138 may assume a minimum value.

In Fig. 5B, in a top-view onto the sensor regions 136 of the longitudinal optical sensors 132 in Fig. 5A, a development of the light spots 184 generated by the light beam 138 impinging on the sensor regions 136 is depicted. As can be seen, close to the focal point 194, the cross-section of the light spot 184 assumes a minimum value.

In Fig. 5C, a photo current I of the longitudinal optical sensors 132 is given for the five cross-sections of the light spot 184 in Fig. 5B, in case longitudinal optical sensors 132 exhibiting the above-mentioned FiP effect are used. Thus, as an exemplary embodiment, five different photo currents I for the spot cross-sections as shown in Figs. 5B are shown for typical DSC devices preferably sDSC devices. The photo current I is depicted as a function of the area A of the light spot 184, which is a measure of the cross-section of the light spots 184.

As can be seen in Fig. 5C, the photo current I , even if all longitudinal optical sensors 132 are illuminated with the same total power of the illumination, the photo current I is dependent on the cross-section of the light beam 138, such as by providing a strong dependency on the cross-sectional area A and/or the beam waist of the light spot 184. Thus, the photo current is a function both of the power of the light beam 138 and of the cross-section of the light beam 138:

$$I=f(n,a).$$

Therein, I denotes the photo current provided by each longitudinal optical sensor 132, such as a photo current measured in arbitrary units, as a voltage over at least one measurement resistor and/or in amps. n denotes the overall number of photons impinging on the sensor region 136 and/or the overall power of the light beam in the sensor region 136. A denotes the beam cross-section of the light beam 138, provided in arbitrary units, as a beam waist, as a beam diameter of beam radius or as an area of the light spot 134. As an example, the beam cross-section may be calculated by the $1/e^2$ diameter of the light spot 184, i.e. a cross-sectional distance from a first point on a first side of a maximum intensity having an intensity of $1/e^2$ as compared to the maximum intensity of the light spot 184, to a point on the other side of the maximum having the same intensity. Other options of quantifying the beam cross-section are feasible.

The setup in Fig. 5C shows the photo current of a longitudinal optical sensor 132 according to the present invention which may be used in the detector 110 according to the present invention, showing the above-mentioned FiP effect. Contrarily, Fig. 5D in a diagram corresponding to the diagram of Fig. 5C, photo currents of traditional optical sensors are shown, for the same setup as depicted in Fig. 5A. As an example, silicon photo detectors may be used for this measurement. As can be seen, in these traditional measurements, the photo current or photo signal of the detectors is independent from the beam cross-section A .

Thus, by evaluating the photo currents and/or other types of longitudinal sensor signals of the longitudinal optical sensors 132 of the detector 110, the light beam 138 may be characterized. Since the optical characteristics of the light beam 138 depend on the distance of the object 112 from the detector 110, by evaluating these longitudinal sensor signals, a position of the object 112 along the optical axis 116, i.e. a z-position, may be determined. For this purpose, the photo currents of the longitudinal optical sensors 132 may be transformed, such as by using one or more known relationships between the photo current I and the position of the object 112, into at least one item of information on a longitudinal position of the object 112, i.e. a z-position. Thus, as an example, the position of the focal point 194 may be determined by evaluating the sensor signals, and a correlation between the focal point 194 and a position of the object 112 in the z-direction may be used for generating the above-mentioned information. Additionally or alternatively, a widening and/or narrowing of the light beam 138 may be evaluated by comparing the sensor signals of the longitudinal sensors 132. As an example, known beam properties may be assumed, such as a beam propagation of the light beam 138 according to Gaussian laws, using one or more Gaussian beam parameters.

Further, the use of a plurality of longitudinal optical sensors 132 provides additional advantages as opposed to the use of a single longitudinal optical sensor 132. Thus, as outlined above, the overall power of the light beam 138 generally might be unknown. By normalizing the longitudinal sensor signals, such as to a maximum value, the longitudinal sensor signals might be rendered independent from the overall power of the light beam 138, and a relationship

$$I_n = g(A)$$

may be used by using normalized photo currents and/or normalized longitudinal sensor signals, which is independent from the overall power of the light beam 138.

Additionally, by using the plurality of longitudinal optical sensors 132, an ambiguity of the longitudinal sensor signals may be resolved. Thus, as can be seen by comparing the first and the last image in Fig. 5B and/or by comparing the second and the fourth image in Fig. 5B, and/or by comparing the corresponding photo currents in Fig. 5C, longitudinal optical sensors 132 being positioned at a specific distance before or behind the focal point 194 may lead to the same longitudinal sensor signals. A similar ambiguity might arise in case the light beam 138 weakens during propagations along the optical axis 116, which might generally be corrected empirically and/or by calculation. In order to resolve this ambiguity in the z-position, the plurality of longitudinal sensor signals clearly shows the position of the focal point and of the maximum. Thus, by e.g. comparing with one or more neighboring longitudinal sensor signals, it may be determined whether a specific longitudinal optical sensor 132 is located before or beyond a focal point on the longitudinal axis.

In Figure 5E, a longitudinal sensor signal for a typical example of an sDSC is depicted, in order to demonstrate the possibility of the longitudinal sensor signal and the above-mentioned FiP

effect being dependent on a modulation frequency. In this figure, a short-circuit current I_{sc} is given as the longitudinal sensor signal on the vertical axis, in arbitrary units, for a variety of modulation frequencies f . On the horizontal axis, a longitudinal coordinate z is depicted. The longitudinal coordinate z , given in micrometers, is chosen such that a position of a focus of the light beam on the z -axis is denoted by position 0, such that all longitudinal coordinates z on the horizontal axis are given as a distance to the focal point of the light beam. Consequently, since the beam cross-section of the light beam depends on the distance from the focal point, the longitudinal coordinate in Figure 5E denotes the beam cross-section in arbitrary units. As an example, a Gaussian light beam may be assumed, with known or determinable beam parameters, in order to transform the longitudinal coordinate into a specific beam waist or beam cross-section.

In this experiment, longitudinal sensor signals are provided for a variety of modulation frequencies of the light beam, for 0 Hz (no modulation), 7 Hz, 377 Hz and 777 Hz. As can be seen in the figure, for modulation frequency 0Hz, no FiP effect or only a very small FiP effect, which may not easily be distinguished from the noise of the longitudinal sensor signal, may be detected. For higher modulation frequencies, a pronounced dependency of the longitudinal sensor signal on the cross section of the light beam may be observed. Typically, modulation frequencies in the range of 0.1 Hz to 10 kHz may be used for the detector according to the present invention, such as modulation frequencies of 0.3 Hz.

Human-machine interface, entertainment device and tracking system:

In Fig. 6, an exemplary embodiment of a human-machine interface 196 according to the invention, which can simultaneously also be embodied as an exemplary embodiment of an entertainment device 198 according to the invention or which can be a constituent part of such an entertainment device 198, is depicted. Further, the human-machine interface 196 and/or the entertainment device 198 may also form an exemplary embodiment of a tracking system 199 adapted for tracking a user 200 and/or one or more body parts of the user 200. Thus, a motion of one or more of the body parts of the user 200 may be tracked.

By way of example, at least one detector 110, according to the present invention can once again be provided, for example, in accordance with one or more of the embodiments described above, with one or a plurality of optical sensors 114, which may comprise one or more transversal optical sensors 130 and one or more longitudinal optical sensors 132. Further elements of the detector 110 can be provided, which are not illustrated in Fig. 6, such as, for example, elements of an optional transfer device 120. For a potential embodiment, reference may be made to Fig. 1A and/or B. Furthermore, one or a plurality of illumination sources 192 may be provided. Generally, with regard to these possible embodiments of the detector 110, reference can be made for example to the description above.

The human-machine interface 196 can be designed to enable an exchange of at least one item of information between a user 200 and a machine 202, which is merely indicated in Fig. 6. For example, in exchange of control commands, and/or information may be performed by using the human-machine interface 196. The machine 202 can comprise, in principle, any desired device
5 having at least one function which can be controlled and/or influenced in some way. At least one evaluation device 142 of the at least one detector 110 and/or a part thereof can, as indicated in Fig. 6, be wholly or partially integrated into said machine 201, but can, in principle, also be formed fully or partially separately from the machine 202.

The human-machine interface 196 can be designed for example to generate, by means of the detector 110, at least one item of geometrical information of the user 200 by means of the detector 110 and can assign the geometrical information at least to one item of information, in particular at least one control command. For this purpose, by way of examples, by means of the detector 110, a movement and/or a change in posture of the user 200 can be identified. For
15 example, as indicated in Fig. 6, a hand movement and/or a specific hand posture of the user 200 may be detected. Additionally or alternatively, other types of geometrical information of the user 200 may be detected by the one or more detectors 110. For this purpose, one or more positions and/or one or more position information regarding the user 200 and/or one or more body parts of the user 200 may be identified by the at least one detector 110. It is then possible
20 to recognize, for example by comparison with a corresponding command list, that the user 200 would like to effect a specific input, for example would like to give the machine 202 a control command. As an alternative or an addition to direct diametrical information about the actual user 200, it is also possible, for example, to generate at least one item of geometrical
25 information about at least one beacon device 204 attached to the user 200, such as at least one item of geometrical information about a garment of the user 200 and/or a glove and/or an article moved by the user 200, such as a stick, a bat, a club, a racket, a cane, a toy, such as a toy gun. One or more beacon devices 204 may be used. The beacon device 204 may be embodied as an active beacon device and/or as a passive beacon device. Thus, the beacon device 204 may
30 comprise one or more illumination sources 192 and/or may comprise one or more reflective elements for reflecting one or more primary light beams 206, as indicated in Fig. 6.

The machine 202 can furthermore comprise one or a plurality of further human-machine interfaces, which need not necessarily be embodied according to the invention, for example, as indicated in Fig. 6, at least one display 208 and/or at least one keyboard 210. Additionally or
35 alternatively, other types of human-machine interfaces may be provided. The machine 202 can, in principle, be any desired type of machine or combination of machines, such as a personal computer.

The at least one evaluation device 142 and/or parts thereof may further function as a track
40 controller 201 of the tracking system 199. Additionally or alternatively, one or more additional track controllers 201 may be provided, such as one or more additional data evaluation devices. The track controller 201 may be or may comprise one or more data memories, such as one or

more volatile and/or non-volatile memories. In this at least one data memory, a plurality of subsequent positions and/or orientation of one or more objects of parts of an object may be stored, in order to allow for storing a past trajectory. Additionally or alternatively, a future trajectory of the object and/or parts thereof may be predicted, such as by calculation, extrapolation or any other suitable algorithm. As an example, a past trajectory of an object or a part thereof may be extrapolated to future values, in order to predict at least one of a future position, a future orientation and a future trajectory of the object or a part thereof.

In the context of an entertainment device 198, said machine 202 can be designed for example to carry out at least one entertainment function, for example at least one game, in particular with at least one graphical display on the display 208 and, optionally, a corresponding audio output. The user 200 can input at least one item of information, for example via the human-machine interface 196 and/or one or more other interfaces, wherein the entertainment device 198 is designed to alter the entertainment function in accordance with the information. By way of example, specific movements or one or more virtual articles, for example of virtual persons in a game and/or movements of virtual vehicles in a game, may be controlled by means of corresponding movements of the user 200 and/or one or more body parts of the user 200, which, in turn, may be recognized by the detector 110. Other types of control of at least one entertainment function by the user 200, by means of the at least one detector 110, are also possible.

Exemplary embodiments of sDSCs for a 3-D position sensor:

The practical implementation of the FiP-effect of the sDSCs in the form of a 3-D sensor, and achieving good spatial resolution both in the x,y- and in the z-direction, typically may require the cells to have an active area of approximately 1 cm x 1 cm and meet certain requirements. Therefore, in the following, preferred requirements for the individual cells of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor are given. It shall be noted, however, that other embodiments are feasible.

Optical properties of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor:

As can be seen in Figures 5A to 5C, one particular current signal can imply two different spatial points (in front and behind the focus). In order to obtain unambiguous depth information on the z-axis, therefore, preferably at least two cells need to be arranged one behind the other. Unambiguous information is then derived from the ratio between the current signals of the two cells. For the sake of precise z-information, this sensor should have six cells stacked behind each other. This requires the cells to be transparent, i.e. the back electrode that normally consists of vapor-deposited silver across its entire area needs to be replaced by a transparent conducting material.

To ensure that sufficient illumination reaches the last cell and it supplies a useful current signal, the front five cells may have only low absorption at the excitation wavelength. The wavelength used for excitation should be around 700 nm.

5 Cross-resistance of the transversal optical sensors:

To achieve precise x,y resolution, there has to be a sufficient potential difference between each pair of opposite sides in this square cell. Fig. 2A shows such a transparent cell with which the x,y resolution is possible.

10

Even without a silver back electrode, sufficiently good electron transport from the p-type conductor into the oxidized dye has to be ensured across the entire surface area of the cells so that the dye is regenerated rapidly by a supply of electrons. Since the p-type conductor itself has very low conductance (10^{-5} S/cm), a conducting layer needs to be coated onto the p-type

15 conductor. Thanks to this additional layer, a defined cross-resistance R is to be achieved between the opposite sides of this square cell.

Transparency of the transversal optical sensors:

20

Due to their good conductance, normal solar cells have back electrodes (second electrodes) made of silver. The cells being developed here, however, have to be transparent, which is why the 1 cm² cell area typically requires a transparent back electrode. The material preferably used for this purpose is the conducting polymer poly(3,4-ethylenedioxythiophene)-poly(styrenesulfonate) (PEDOT:PSS) in aqueous dispersion. The conjugated polymer

25 PEDOT:PSS is highly transparent; it absorbs in the blue-green region (450-550 nm) only at considerable layer thicknesses, and only minimally in the red spectral range.

30

The additional PEDOT layer makes possible good electron transport in the p-type conductor. To improve the conductance of this layer and provide contacts, four silver electrodes 1 cm in length are vapor-deposited around the square cell. The arrangement of the silver electrodes is shown in Fig. 3.3a. Fig. 3.3b shows a cell with a transparent PEDOT back electrode.

Extinction of the cells of the at least one transversal optical sensor and/or the at least one longitudinal optical sensor:

35

It is not only the back electrode that has to be transparent, but the entire cell. To ensure that a sufficient amount of light still reaches the last cell in the stack, the extinction of the front five cells should be as low as possible. This is determined first and foremost by the dye's absorption. The extinction of a solar cell, i.e. the absorption of light by the dye, has a decisive

40 effect on the cell's output current. Typically, the wavelength-dependent absorption spectrum has a maximum – the wavelength of maximum absorption is characteristic of the particular dye used. The more dye has been adsorbed in the np TiO₂ layer, the higher the cell's absorption.

The more dye molecules are adsorbed, the more electrons can reach the cb of the TiO₂ through optical excitation and the higher the current. A cell with higher extinction will, therefore, have a higher output current than one with low extinction.

- 5 The objective here is to obtain the maximum total current from the complete cell arrangement – which in the ideal case is divided equally among all the cells. Since the intensity of the light is attenuated by absorption in the cells, the ones located further back in the stack receive less and less light. In order, nonetheless, to obtain similar output currents from all six cells, it would make sense for the front cells to have lower extinction than the ones at the back. As a result, they will
- 10 stop less of the light reaching the following cells, which in turn will absorb a larger proportion of the already weakened light. Through optimal adjustment of the extinctions at the positions of the cells in the stack, in this way theoretically one could obtain the same current from all the cells. The extinction of a solar cell can be adjusted by staining with a dye and by controlling the thickness of the np TiO₂ layer.

15

Optimizing the extinction and the output current of the cells of the longitudinal optical sensor stack:

- 20 The last cell in the stack preferably should absorb almost all the incident light. For this reason, this cell should have maximum extinction. Starting with the current obtained under maximum extinction at the last cell, the extinctions of the front cells need to be so adjusted that all cells together supply a maximum total current, one that is distributed as uniformly as possible across all the cells.

- 25 Optimizing the stack's output currents is carried out as follows:

- The choice of dye
- Maximum extinction/maximum output current of the last cell
- Dye concentration for staining the last cell

30

- Staining time of the last cell
- Optimum thickness of the last cell's np TiO₂ layer
- Maximum output current of the complete stack
- Optimum thickness of the np TiO₂ layers of the front five cells

- 35 The extinction was measured with a Zeiss spectrometer MCS 501 UV-NIR using Zeiss lamp MCS 500. The results were evaluated with an Aspect Plus software program.

Choice of dye:

- 40 To begin with, a dye should be found that absorbs sufficiently at the excitation wavelength of approximately 700 nm. The ideal dye for solar cells typically has a broad absorption spectrum and should absorb completely the incident light below a wavelength of ca. 920 nm. In actual

fact, most dyes have an absorption maximum in the wavelength range between 450-600 nm; above 650 nm they usually absorb weakly or not at all.

The dye with which the first experiments were performed was ID504, as e.g. disclosed in WO 2012/110924 A1. This dye, however, turned out to exhibit only a low absorption in the range of 700 nm. Therefore, for the stack, the dye D-5 (also referred to as ID 1338) was used:

Preparation and properties of the Dye D-5 are disclosed in WO 2013/144177 A1.

Additionally or alternatively, however, other dyes may be used. The staining time, i.e. the duration of staining of the TiO₂-layer with the respective dye, turned out to have an influence on the absorption properties. The tests were performed with cells having np TiO₂ layers having a thickness of 1.3 microns. The absorption maximum of D-5 is around 550-560 nm which exhibits an extinction $\epsilon \approx 59000$ at this maximum.

In this experimental series, the dye concentration was 0.3 mM and the staining time was increased so as to be 10 to 30 minutes. A pronounced increase in extinction at longer staining times was observed, so finally staining times of 30 min. were used for D-5.

Still, even after optimizing the staining time, the absorption was determined to be rather very low. Therefore, generally, the absorption will have to be maximized by increasing the dye concentration, the staining time and the thickness of the np TiO₂ layer.

Dye concentration and staining time of the last cell in the longitudinal optical sensor stack:

Several experiments regarding the staining time and the dye concentration were performed. The standard concentration of the dye solution for a layer thickness of the TiO₂-layers of 1-2 microns was 0.5 mM. At these concentrations, the dye should already be present in excess. Here the dye concentration was increased to 0.7 mM. In order to prevent inhomogeneities across the cell's area, the dye solution was cleaned by removing undissolved dye particles and other impurities, using a 0.2 micron syringe filter, before placing the cells in it.

If the dye is present in excess, then after a 1 hour staining time a dye monolayer dye should have been adsorbed to the surface of the np TiO₂ layer, which leads to maximum absorption by

the dye being used. The maximum staining time tested here was 75 minutes, which was finally used for the cells.

Finally, cells having a layer thickness of the TiO₂-layer of 1.3 microns, a dye concentration of 0.7 mM and a staining time of 75 min was used. The cell's extinction turned out to be 0.4 at 700 nm.

The np TiO₂ layer thickness of the last cell of the longitudinal optical sensor stack:

Ultimately, the thickness of the nanoporous (np) layer and thus the TiO₂ surface area available for dye adsorption may be an important factor influencing the absorption behavior and therefore the cells' output current. So far, maximizing the extinction was done in cells with np TiO₂ layers whose thickness was 1.3 microns. Since more dye can be adsorbed in thicker np TiO₂ layers, the thickness of the TiO₂ layer was increased in steps to 3 microns, and the thickness at which the greatest output current occurred was determined.

The nanoporous TiO₂ layers were applied by spin coating. Spin coating is suitable for applying low-volatility substances dissolved in a high-volatility solvent (here: terpineol). As a starting product, TiO₂ paste made by Dyesol (DSL 18 NR-T) was used. This paste was mixed with terpineol, which decreases the viscosity of the paste. Depending on the composition ratio of the paste : terpineol mixture, and at a constant spin velocity of 4500 1/min, np TiO₂ layers of varying thicknesses are obtained. The higher the terpineol proportion, the lower the viscosity of the diluted paste and the thinner the cells will be.

The diluted TiO₂ paste was also cleaned using a 1.2 micron syringe filter to remove larger particles, before applying the paste the next day by spin coating on the cells coated with blocking layer.

When varying the np TiO₂ layer thickness, it should be noted that the concentration of the p-type conductor dissolved in chlorobenzene needs to be adjusted. Thicker np layers have a larger cavity volume that has to be filled with p-type conductor. For this reason, in the case of thicker np layers the amount of supernatant p-type conductor solution on top of the np layer is smaller. To ensure that the solid p-type conductor layer remaining on the np TiO₂ layer after spin coating has a constant thickness (the solvent evaporates during spin coating), higher p-type conductor concentrations are needed for thick np TiO₂ layers than for thin ones. The optimal p-type conductor concentrations are not known for all the TiO₂ layer thicknesses tested here. For this reason, the p-type conductor concentration is varied for the unknown layer thicknesses and the output currents compared for equal layer thicknesses but different p-type conductor concentrations.

The chosen starting value for the layer thickness variation was a 1.3 microns for the np TiO₂ layer. 1.3 microns corresponds to a TiO₂ paste : terpineol mass composition of 5 g : 5 g. A test

series with cells whose np TiO₂ layers are thicker than 1.3 microns will show at which layer thickness the largest output current is obtained from the last cell in the stack.

These cells were stained with the aforementioned optimized parameters for maximum extinction (D-5; c = 0.7 mM; staining time: 75 minutes). The extinction of these cells was found to be approximately 0.6 at 700 nm.

Since the last cell generally does not have to be transparent, the back electrode was vapor-deposited on the whole 1 cm² area directly onto the p-type conductor – without PEDOT.

The measurement results indicated that, as expected, the output currents of the cells with a whole-area back electrode (second electrode) are much higher. Highest output currents were obtained with a TiO₂ : terpineol mass ratio of 5 : 3. This corresponds to a TiO₂ layer thickness of 2-3 microns.

Therefore, in subsequent experiments, a TiO₂ paste : terpineol composition of 5 : 3 was used for the last cell in the stack. The back electrode was vapor-deposited across the entire 1 cm² cell area.

The np TiO₂ layer thickness of the front cells of the longitudinal optical sensor stack:

Starting from the maximum output current obtained with the last cell, the thicknesses of the front cells' np TiO₂ layers are to be so adjusted that every cell in the stack generates the maximum possible output current. This requires low extinction values in the front cells.

During the experiments, it turned out that, in practical terms, it is rather difficult to obtain reproducible low extinctions through the dye concentration and staining time parameters. In order to make cells with low, reproducible extinction, therefore, it makes sense to fabricate cells with thin np TiO₂ layers and to keep them in the dye solution for the time needed to ensure dye saturation of the np TiO₂ surface. The terpineol proportion in the TiO₂ layers was increased in a stepwise fashion. All the cells were stained under the same conditions. Since their extinction is intended to be decreased significantly, the dye concentration here was 0.5 mM, and the staining time was 60 minutes.

Surprisingly, in this series, the cell's output voltages turned out to begin with an increase in output current with decreasing np TiO₂ layer thickness. The optimum out of the tested TiO₂ paste dilutions turned out to be 5 : 6. At higher dilutions and therefore thinner np TiO₂ layers, the output current tends to decrease. The reason for the exception to this trend at a dilution of 5 : 9 is likely to be optimal adjustment of the p-type conductor concentration of 100 mg/ml for this layer thickness.

If, however, one considers the decrease in extinction relative to that of the output current, it makes sense to accept the lower output current in order to ensure that the following cells receive very much more light than would be the case with 5 : 6 dilution. Photographs of cells with TiO₂ : terpineol mixtures of 5 : 4.1, 5 : 6 and 5 : 10 were taken, which illustrated this effect.

- 5 Effects of inhomogeneity were observed. In order to achieve a homogeneous layer within a 1 cm² cell, the TiO₂ area was increased for later cells such that the region in which the TiO₂ banks up during spin coating lies outside the silver electrodes and thus outside the cell.

- 10 The construction of the cell stack with regard to the TiO₂ layer's thickness in the cells and their positioning in the stack, was carried out by testing various arrangements of cells with np TiO₂ layers of various thicknesses.

Preparation and the properties of a dye sensitized solar cell (DSC) prepared with the Dye D-5

- 15 FTO (tin oxide doped with fluorine) glass substrates (< 12 ohms/sq, A11DU80, supplied by AGC Fabritech Co., Ltd.) were used as the base material, which were successively treated with glass cleaner, Semico Clean (Furuuchi Chemical Corporation), fully deionized water and acetone, in each case for 5 min in an ultrasonic bath, then baked for 10 minutes in isopropanol and dried in a nitrogen flow.

- 20 A spray pyrolysis method was used to produce the solid TiO₂ buffer layer. Titanium oxide paste (PST-18NR, supplied by Catalysts & Chemicals Ind. Co., Ltd.) was applied onto the FTO glass substrate by screen printing method. After being dried for 5 minutes at 120°C, a working electrode layer having a thickness of 1.6 µm was obtained by applying heat treatment in air at 25 450°C for 30 minutes and 500°C for 30 minutes. Obtained working electrode is then treated with TiCl₄, as described by M. Grätzel et al., for example, in Grätzel M. et al., Adv. Mater. 2006, 18, 1202. After sintering the sample was cooled to 60 to 80°C. The sample was then treated with an additive as disclosed in WO 2012/001628 A1. 5 mM of the additive in ethanol was prepared and the intermediate was immersed for 17 hours, washed in a bath of pure ethanol, briefly dried in a 30 nitrogen stream and subsequently immersed in a 0.5 mM solution of dye D-5 in a mixture solvent of acetonitrile + t-butyl alcohol (1:1) for 2 hours so as to adsorb the dye. After removal from the solution, the specimen was subsequently washed in acetonitrile and dried in a nitrogen flow.

- 35 A p-type semiconductor solution was spin-coated on next. To this end a 0.165M 2,2',7,7'-tetrakis(N,N-di-p-methoxyphenyl-amine)-9,9'-spirobifluorene (spiro-MeOTAD) and 20mM LiN(SO₂CF₃)₂ (Wako Pure Chemical Industries, Ltd.) solution in chlorobenzene was employed. 20 µl/cm² of this solution was applied onto the specimen and allowed to act for 60 s. The supernatant solution was then spun off for 30 s at 2000 revolutions per minute. The substrate 40 was stored overnight under ambient conditions. Thus, the HTM was oxidized and for this reason the conductivity increased.

As the metal back electrode, Ag was evaporated by thermal metal evaporation in a vacuum at a rate of 0.5 nm/s in a pressure of 1×10^{-5} mbar, so that an approximately 100 nm thick Ag layer was obtained.

- 5 In order to determine the photo-electric power conversion efficiency η of the above photoelectric conversion device, the respective current/voltage characteristic such as short-circuit current density J_{sc} , open-circuit voltage V_{oc} and fill factor FF was obtained with a Source Meter Model 2400 (Keithley Instruments Inc.) under the illumination of an artificial sunlight (AM 1.5, 100 mW/cm² intensity) generated by a solar simulator (Peccell Technologies, Inc). As a result, the
- 10 DSC prepared with the Dye D-5 exhibited the following parameters:

J_{sc} [mA/cm ²]	V_{oc} [mV]	FF [%]	η [%]
10.5	721	59	4.5

Results of the optimized output currents for the longitudinal optical sensor stack:

- 15 The best result in terms of the cell stack's output currents were obtained when all five transparent cells of the longitudinal optical sensors step have an np TiO₂ layer thickness of 0.45 micrometers (i.e. a TiO₂ paste dilution of 5 : 10). These cells with a 0.45 micrometers np TiO₂ layer were stained for 60 minutes in a 0.5 mM dye solution. Only the last cell had a np TiO₂ layer just under 3 micrometers and was stained for 75 minutes (0.7 mM). Since the last cell
- 20 does not have to be transparent, the back electrode (second electrode) of the last cell was a vapor-deposited silver layer across the whole 1 cm² area so as to be able to pick up the maximum possible current. The following photo currents were observed with this stack, in order from the first cell to the last cell of the stack :

25 Current [μ A]: 37 9.7 7.6 4.0 1.6 1.9

- The first five cells were made identically. The last cell had a thicker np TiO₂ layer and a silver back electrode vapor-deposited across the whole cell area. One can see that the current of the second cell has already dropped to 1/4 of the first cell's. Even in these five highly transparent
- 30 cells, the last cell's current is only a fraction of the current in the first cell. The cells were excited with a red laser (690 nm, 1 mW) directed at the centre of the cell area.

- The current obtained with cells with a TiO₂ : terpineol dilution of 5 : 9, 5 : 8 or 5 : 7 (i.e. thicker cells) was at most 10 microamps larger than the current of a cell with 5 : 10 dilution of the TiO₂ paste. These cells, however, exhibited a significantly higher extinction, as a result of which the
- 35 output current of the following cells decreases considerably.

- The cells with a TiO₂ dilution of 5 : 6, in which – compared with the TiO₂ dilutions of 5 : 9; 5 : 8 and 5 : 7 – a significantly higher current was obtained, nevertheless absorbed so much light that
- 40 no more light reaches the last cell of the stack. Even when placing just one of these cells in

position 5 with four preceding 450 nm thin cells, the output current of the last cell decreased considerably, such that the last cell supplies practically no more current.

It needs mentioning that each of these cells in the test stack was sealed with an additional glass plate for protection against ambient effects. This, however, created many additional interfaces at which the light beam of the 690 nm laser (1 mW) can be reflected and scattered, as a result of which the extinction of such a sealed cell is higher. In the later device the cell stack was kept in nitrogen, which is why the sealing becomes unnecessary and the cells lie directly on top of each other. This decreased the stack's extinction, since the losses resulting from scattering at the cover glasses no longer occur.

Cross-resistance of the transversal optical sensors:

A defined cross-resistance between the opposite sides of the square cell makes precise x,y resolution possible. The principle of x,y resolution is illustrated in Figures 3A to 3D. The cross-resistance across the area of the cell is determined by the PEDOT layer present between the p-type conductor and the silver electrodes bordering the cell. In the undoped state, PEDOT is a semiconductor. Conductivity is made possible by the system of conjugated double bonds extending across the entire molecule in combination with the doping with a negatively charged counter-ion. The PEDOTs used which were used for the present experiments were all doped with the negatively charged polymer polystyrene sulfonate (PSS). PEDOT:PSS is available in a wide range of embodiments as regards conductance, solid content, ionisation potential (IP), viscosity and pH.

Factors affecting the cross-resistance:

The PEDOT was also applied to the cells by spin coating. During the spinning process, the solvents ethanol and isopropanol evaporate whereas the low-volatility PEDOT remains on the substrate in the form of a film. The resistance of this layer depends on the conductance of the PEDOT being used and on the thickness of the layer:

$$R = \rho \cdot \frac{l}{A}$$

where ρ is the resistivity, l the distance across which the resistance is measured and A the cross-sectional area through which the charge carriers flow (A is a function of the PEDOT layer's thickness).

According to known principles of spin-coating, the layer thickness d to be expected when coating a non-Newtonian fluid can be determined by:

$$d = \sqrt[3]{\frac{3 \cdot x_s^3 \cdot u_k \cdot e}{2 \cdot (1 - x_s) \cdot \omega^2}}$$

$$\sim \sqrt[3]{\frac{x_s^3 \cdot u_k}{(1 - x_s) \cdot \omega^{3/2}}}$$

where x_s is the PEDOT percentage in the mixed diluted solution, u_k is the kinematic viscosity, e the evaporation rate of the solvent(s) and ω the angular velocity during spin coating. The evaporation rate is proportional to $\omega^{1/2}$.

The thickness of the PEDOT layer can, therefore, be affected by various parameters: the angular velocity, the viscosity of the PEDOT solution and the percentage of PEDOT in the solution. The angular velocity can be varied directly. The viscosity and the percentage of PEDOT in the solution can only be affected indirectly, i.e. via the ratio at which the PEDOT is mixed with ethanol and isopropanol.

The following parameters, therefore, can be used in order to adjust the cross-resistance, and they will be optimized in due course:

- The choice of PEDOT
- The layer thickness of the PEDOT
- The PEDOT/solvent ratio
- The spin speed during the PEDOT's spin coating
- The number of PEDOT layers
- The time interval Δt between applying and spin coating the PEDOT

Optimizing the cross-resistance:

The PEDOT solution was mixed with ethanol and isopropanol in a standard volumetric ratio of 1: 1 : 1, and larger particles removed with a 0.45 micrometer syringe filter. The entire cell was covered with this diluted PEDOT solution (approximately 900 microliters were needed per substrate) and spin coated at a speed of 2000 1/s. At this speed, 30 s turned out to suffice to remove and evaporate the solvents ethanol and isopropanol.

The aforementioned parameters were then varied systematically, with the objective of obtaining a cross-resistance of ca. 2 k Ω between the opposite electrodes of the square cell.

Choice of PEDOT:

The greatest impact on the PEDOT layer's cross-resistance turned out to come from the conductance of the PEDOT solution used. In order to obtain a first impression of the order of magnitude of the resistances of such a PEDOT layer across 1 cm, three PEDOT products with very different conductances were tested:

- Clevios™ PVP AI 4083 from Heraeus
- Clevios™ PH 1000 from Heraeus
- Orgacon™ N-1005 from Sigma Aldrich

The relevant parameters of dynamic viscosity η_d , ionisation potential IP and resistivity ρ are summarised in Table 1. The IP is an important selection criterion for the PEDOT. The PEDOT's IP generally should be less than 5 eV in order to ensure good functionality of the cell.

	AI 4083	PH 1000	N-1005
η_d [mPas]	5 - 12	15 - 50	7 - 12
IP [eV]	5.2	4.8	N/A
ρ [Ωcm]	500 - 5000	0.0012	75 - 120

Table 1: Relevant parameters for various PEDOTs.

For these first tests, 1.3 micrometer np TiO₂ layers were coated onto FTO-free glass substrates. In this first experimental series, only 300 microliters of each of the three prepared PEDOT solutions were coated directly on np TiO₂ layers – without the staining or p-type conductor coating steps. For each PEDOT solution, three substrates with 1, 2 and 3 PEDOT layers were made. The resistance was measured by applying a layer of conducting silver paint at 1 cm spacing at several positions on each substrate.

It is to be expected that the resistance of the substrate fabricated in this way, will be smaller than the resistance resulting from applying the PEDOT on a smooth p-type conductor layer.

As expected, the experiments showed a decrease in cross-resistance with an increasing number of layers and therefore increasing total thickness of the PEDOT. The cross-resistance of AI 4083 is in the M Ω range even with three layers, therefore it was not used in further tests. PH 1000 with two applied layers was in the required range. The cross-resistance of N 1005 is also in the k Ω range, and could be decreased through optimization. Since, however, it can be assumed that when applying the PEDOT on the smooth p-type conductor's surface the resistance will be higher than when applying it directly on the np TiO₂ layer as in this test series, further optimizations will focus on PH 1000.

Applying several PEDOT layers:

A further option for increasing the total thickness of the PEDOT layer is to apply several PEDOT layers consecutively. Tests were conducted with 1 and 2 applied PEDOT layers. PH 1000 was mixed with ethanol and isopropanol at a 1 : 1 : 1 volumetric ratio. The cells were covered completely with 900 microliters of the PEDOT solution and the excess solution was removed by spin coating at an RPM of 2000 1/min.

Unlike the first experimental series, these tests were conducted on 'complete' cells, i.e. stained cells coated with p-type conductor. The cross-resistance was measured between two circular vapour-deposited electrodes ca. 2 mm apart, in order to exclude errors resulting from different contact resistances of PEDOT/conducting silver paint and PEDOT/vapour-deposited silver. In addition, cell efficiency measurements can be automated with this electrode arrangement. These test cells are very much simpler and quicker to make than the square transparent ones, but they suffice for the requirements of these tests (for one thing, the cross-resistance of the PEDOT layer(s) is to be measured here across a defined section; for another, the cells are to be tested for functionality, i.e. whether there is good contact between the p-type conductor and the PEDOT and the IP of the PEDOT matches the energy level of the p-type conductor). The cross-resistance across 1 cm is calculated using equation 3.1 – assuming equal layer thickness and therefore equal area A – through multiplication by the factor 5 (the resistivity of the solution is constant).

Table 2 shows the results of the resistance measurement between the two circular vapor-deposited back electrodes and the calculated cross-resistances across 1 cm for 1 and 2 PEDOT layers. The last column shows the efficiency of the cells. The smallest and largest measurements obtained in several tests are shown in each case.

Mixture ratio	Number of layers	RPM [1/min]	$R_{l=2mm}$ [k Ω]	$R_{l=1cm}$ [k Ω]	η [%]
1 : 1 : 1	1	2000	6 - 19	30 - 90	1.5 - 2.5
	2		0.18 - 0.27	0.9 - 1.35	0.4 - 0.6

Table 2: Results of resistance measurements for one and two PEDOT layers.

The difference in cross-resistances between one and two applied PEDOT layers can be seen clearly. For one PEDOT layer it is significantly higher than the required 2 k Ω , for two layers it is very much lower. It is also evident, however, that the efficiency of the cells with two applied PEDOT layers is very much smaller, which means that the contact between the two PEDOT layers is poor. It should be noted that the efficiency being measured here refers to the circular cell, i.e. to a cell with a back electrode vapor-deposited across the whole surface. The efficiency of the square transparent cells, therefore, will be much lower still, which is why the idea of several PEDOT layers applied consecutively has to be discarded. Further experiments will attempt to minimize the cross-resistance of one PEDOT layer only.

It is noticeable that the resistance with two applied PEDOT layers is smaller than in the first experimental series, in which the PEDOT was applied directly onto the np TiO₂ layer. Presumably, the reason for this discrepancy is that in the first experiments the layers were applied immediately after each other, even though the first PEDOT layer had not yet dried out completely. In this experiment, the cell was placed on the hotplate at 60 °C between applying the two layers.

As expected, in this experimental series – in which the PEDOT was applied onto the p-type conductor – the cross-resistance with only one applied PEDOT layer was higher than when the PEDOT was applied onto the rough surface of the np TiO₂.

Increasing the PEDOT concentration of the solution:

As mentioned above, usually, the PEDOT solution is mixed with ethanol and isopropanol at a volume ratio of 1 : 1 : 1 in order to decrease the viscosity of the solution and obtain homogeneous layers through spin coating. When the PEDOT proportion in the mixture is increased, the solution's viscosity rises. Due to the higher viscosity, an increase in the thickness of the PEDOT layer remaining on the cell after spin coating is expected (for comparison: η_d , ethanol, 20°C = 1.19 mPas; η_d , isopropanol, 20°C = 2.43 mPas; η_d , PEDOT = 5-50 mPas).

In order to investigate the practical effect of the PEDOT solution's viscosity and the amount of substance it contains on layer thickness and therefore on the cross-resistance, the PEDOT proportion was increased a little to begin with, and then significantly. The volumetric mixture ratios ethanol : isopropanol : PEDOT tested here were as follows:

1 : 1 : 1
1 : 1 : 2
1 : 1 : 5
1 : 1 : 10
2 : 2 : 1

Since a preliminary experiment showed that small variations in PEDOT concentration do not result in significant differences as far as the resistance is concerned, the PEDOT proportion in the mixed solutions was increased considerably. This was the first experimental series in which the construction of the cells and the arrangement of the electrodes corresponded to those of the actual square cells.

The thickness of the cells' np TiO₂ layer was 1.3 micrometers. Each time, a PEDOT layer with a different proportion of PH 1000 was applied. The PEDOT solution was spun for 90 seconds at 2000 or 1500 1/min. Then the PEDOT layer was dried for ca. 1 minute with the hot air blower, before the silver electrodes (ca. 2 micrometers thick) were vapor-deposited.

Mixture	Number	RPM	R
---------	--------	-----	---

ratio	of layers	[1/min]	[k Ω]
1 : 1 : 1	1	2000	22 - 39
1 : 1 : 5			31 - 51
1 : 1 : 10			29 - 36
1 : 1 : 1	1	1500	21 - 27
1 : 1 : 5			21 - 32
1 : 1 : 10			26 - 37

Table 3: Cross-resistances for various mixture ratios and spin speeds of PEDOT layers.

As can be seen in Table 3, the cross-resistance does not decrease as expected with the increasing PEDOT proportion in the applied solution. Both at an angular velocity of 2000 and of 1500 1/min, the cross-resistance increases with the increasing PEDOT concentration in the solution. However, it is also noticeable that the resistance tends to decrease with decreasing RPM for the same PEDOT proportion, but is still 10-15 orders of magnitude too high.

Adjusting the time interval between application and spin coating of the PEDOT (Δt) and minimizing the RPM during spin coating:

The classic method for increasing layer thickness during spin coating is to decrease the angular velocity. In this way, layer thickness can easily be increased and the cross-resistance decreased. In the experimental series thus far, this was the only variation that led to a sensible result. The angular velocity during spin coating cannot, however, be decreased to an arbitrary value, since at excessively low RPM the solvent no longer evaporates sufficiently quickly which results in inhomogeneous PEDOT layers.

Tests have shown, however, that the time interval between applying the PEDOT solution to the substrate and starting the spin coating (and thus, removing excess solution from the substrate) has a significant effect on the cross-resistance. Therefore, subsequently, the cross-resistance was minimized through iterative optimization of the two parameters Δt and angular velocity during spin coating.

Therefore, over several tests series, the time interval Δt between applying the PEDOT solution to the cell and the start of spin coating was increased in steps from 30 seconds to 2 minutes, later in combination with RPM optimization from 1 to 3 minutes and finally from 3.5 to 5 minutes. This involves decreasing the RPM from 2000 1/min to 350 1/min. When decreasing the RPM to under 1000 1/min, 30 seconds turned out to no longer suffice for complete evaporation of the solvent. This time was, therefore, extended to 2 minutes in every case. Thereafter, the cells were dried with the hot air blower for approximately 1 minute before the electrodes were vapor-deposited.

RPM [1/min] 2000 1000 750 600 500 450 400 350

The results of the optimization are summarized in Tables 4 to 7.

- 5 In the first experimental series of the final optimization (Table 4), in which to begin with the time interval Δt between applying the PEDOT solution on the cell and spinning at constant angular velocity was increased, at an RPM of 1000 1/min there seems to be an optimum at $\Delta t = 60$ s (4.1 - 4.2 k Ω). For this time interval and a further decrease in RPM, a new minimum was obtained for 600 1/min (2.6 - 2.7 k Ω).

Mixture ratio	Number of layers	RPM [1/min]	Δt [s]	R [k Ω]
1 : 1 : 1	1	1000	30	8.5 - 8.7
			60	4.1 - 4.2
			90	4.7 - 4.8
			120	5.4 - 5.8
		750	60	9.0 - 9.2
		600	60	2.6 - 2.7
		500	60	3.7 - 4.0

Table 4: Optimization of the cross-resistance by optimizing the time interval Δt and the angular velocity during PEDOT solution spin coating – experimental series 1.

5

Mixture ratio	Number of layers	RPM [1/min]	Δt [s]	R [k Ω]
1 : 1 : 1	1	600	60	15.8 - 17.6
			90	11.0 - 11.6
			120	11.2 - 11.4
		500	60	6.0 - 6.8
			90	5.0
			120	6.4 - 6.8
			180	3.1 - 4.1

Table 5: Optimization of the cross-resistance by optimizing the time interval Δt and the angular velocity during PEDOT solution spin coating – experimental series 2.

10

Mixture ratio	Number of layers	RPM [1/min]	Δt [s]	R [k Ω]
1 : 1 : 1	1	500	180	0.4
		450	180	0.6
		400	180	1.1 - 1.3
		350	180	2.0 - 2.7
		350	210	1.8 - 2.5
		350	240	1.6
		350	270	1.5 - 1.8
		350	300	1.8 - 1.9

Table 6: Optimization of the cross-resistance by optimizing the time interval Δt and the angular velocity during PEDOT solution spin coating – experimental series 3.

Mixture ratio	Number of layers	RPM [1/min]	Δt [s]	R [k Ω]
1 : 1 : 1	1	500	180	1.3 - 2.4
		450	180	1.0 - 2.0

Table 7: Optimization of the cross-resistance by optimizing the time interval Δt and the angular velocity during PEDOT solution spin coating – experimental series 4.

Since, however, the results do not differ substantially between 600 and 500 1/min, in the next experimental series the time interval Δt was increased further stepwise for both RPM values. The results are shown in Table 5.

A further decrease in RPM and increase in Δt did not exhibit further improvement. In fact, the cross-resistance even increased again at an RPM < 450 1/min (see Table 6).

Since the values for 500 and 450 1/min lie very close together, a last comparative test was performed (see Table 7).

It was shown that the cross-resistance at an RPM of 450 1/min is slightly smaller than at 500 1/min. Since, however, no significant is achieved thereby and since PEDOT layers coated at an excessively low RPM are no longer homogeneous, 500 1/min was chosen as the optimal RPM. The time interval Δt is then 180 s.

Generally speaking, it is noticeable that the resistance values in the last set of experimental series, where there was a time interval between applying the PEDOT solution to the cell and starting the spinning, do not fluctuate as much within one series for constant parameters as

before. In the last experimental series (Table 7), the two cross-resistances were measured on each of four cells (left-right and top-bottom) and the results varied only by ca. 1 k Ω . The fact that in some cases the results from different series vary significantly for the same experimental parameters, is likely to be due to the production of the PEDOT solution since the individual experimental series in themselves provide coherent results.

The spin coater's open lid during the time interval Δt may be an important interference factor in these experiments. In one experimental series, it was not closed immediately after applying the PEDOT solution to the cell but only before spin coating. The cross-resistances measured in this experimental series are very much higher and there is a considerable variation in their values between the substrates – but not on any one substrate. It could not be determined exactly why the cross-resistance is so strongly influenced by the time interval Δt before the PEDOT solution's spin coating. Perhaps some of the PEDOT solution dries and adheres to the cell during this time, resulting in a thicker PEDOT layer.

Results of the optimized parameters:

The minimum cross-resistance obtained in this way lies between 1 and 3 k Ω . The parameters that bring about a minimum cross-resistance here were:

- PEDOT: Clevios[®] PH 1000 from Heraeus
- Number of layers: 1
- PEDOT : ethanol : isopropanol ratio = 1 : 1 : 1
- Time interval between applying and spin coating the PEDOT: $\Delta t = 180$ s
- RPM during PEDOT spin coating: $n = 500$ 1/min ($t = 120$ s)

The final cells used in the experiments:

The cells used during the optimization process so far were made on thick 2.5 mm TEC 8 glass carriers, with the FTO layer already applied during the fabrication process. They have a highly homogeneous FTO layer, onto which the application of homogeneous np TiO₂ layers is possible. This makes possible the fabrication of cells that appear homogeneous to the human eye.

For the technical realization of the sensor stack, however, the cells were made on thin 1 mm special glass carriers made of quartz glass, which were coated subsequently with FTO. Therein, loss carriers with beveled edges were used. The beveled edges served as bases for cells contacts. The silver contacts were vapor-deposited up to the edge of the bevels. This made it possible to contact the cells directly adjacent to each other in the stack individually with pins.

The subsequently applied FTO layer on these special carriers exhibited in part inhomogeneities arising from the fabrication process. The fabrication of homogeneous cells on these carriers

turned out to be very difficult, as was shown by generating current diagrams of the final cells. Even in the first cell of the stack which supplied a homogeneous current signal across its entire area, four locations were identified that supplied lower currents due to inhomogeneities. Current diagrams were obtained by exciting the cells with a laser at a wavelength 690 of nm. The laser
5 scanned the cells at 1 mm intervals. The cells were scanned in their final arrangement as a stack, i.e. the current diagram of the last cells was recorded with five 'thin' cells located in front of the last cell.

At the excitation wavelength of 690 nm, the developed cells had an extinction of 0.13. At the
10 maximum (at ca. 550 nm) the extinction of these cells was ca. 0.4. Despite this low absorption by the cells and the fact that the back electrode consists of a poorly conducting – unlike silver – transparent layer, the efficiency of such a cell is still ~0.3% (AM 1.5*), that of the last cell ~2%.

Figures 2A, 4B and 4C show the final cells on the 1 mm special glass carriers. The first cell in
15 the stack, which acts as the transversal optical sensor, requires the special electrode arrangement for x,y-resolution. For cells 2-5, which form the longitudinal optical sensor stack, only the total current is needed for z-resolution, which is why the contacting silver electrodes are combined here into one electrode surrounding the cell. Otherwise, however, the first five cells were made identically.

20 The last cell of the longitudinal optical sensor stack is intended to absorb the remaining light preferably completely, which is why it was chosen to have a significantly higher extinction than the front cells. In addition, it has a back electrode covering its entire area in order to supply maximum output current.

25 The cell shown in Fig. 2A, which forms the transversal optical sensor, in this experiment, was used only once for x,y resolution at position 1 in the stack. The cells in Fig. 4B were used four times in the entire stack of the optical sensors, i.e. for positions 2-5 of the entire stack. The last cell, which is depicted in Fig. 4C, was used at position 6 of the entire stack of optical sensors.
30 Thus, generally, a stack of optical sensors was formed with the first optical sensor being the transversal optical sensor (Fig. 2A), followed by four transparent longitudinal optical sensors (Fig. 4B) and a last longitudinal optical sensor having the set-top of Fig. 4C.

35 When illuminating one of these single transparent final cells with a red laser (690 nm, 1 mW), this cell supplied a current of 30-40 microamps. The last longitudinal optical sensor provided a current of approximately 70 μ A. The cross-resistance between any two opposite electrodes in the first cell on these special glass carriers turned out to be 0.1 and 0.3 k Ω .

40 Since the fabrication of transparent cells on the special glass carriers was problematic due to the poor FTO coating, these cells had to be fabricated in large numbers. The cells were screened, and only selected cells were used for the final setup of the detector forming a prototype 3-D sensor. For this screening procedure, specifically for the transversal optical

sensor, the cells were excited by a laser beam (690 nm, 1 mW) at the center of the cell. If the cells are homogenous, the currents at all four contacts are equal ($I_1 = I_2 = I_3 = I_4$). By comparing the currents, specific cells were selected for use in the prototype.

- 5 The x,y resolution achieved with the detector of the set-top turned out to be approximately 1 mm at a distance of 3 m. The z-resolution of this detective setup turned out to be approximately 1 cm.

Patent claims

1. A detector (110) for determining a position of at least one object (112), comprising:
 - 5 - at least one transversal optical sensor (130), the transversal optical sensor (130) being adapted to determine a transversal position of at least one light beam (138) traveling from the object (112) to the detector (110), the transversal position being a position in at least one dimension perpendicular an optical axis (116) of the detector (110), the transversal optical sensor (130) being adapted to generate at least one transversal sensor signal;
10
 - at least one longitudinal optical sensor (132), wherein the longitudinal optical sensor (132) has at least one sensor region (136), wherein the longitudinal optical sensor (132) is designed to generate at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region (136) by the light beam (138), wherein the
15 longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam (138) in the sensor region (136);
 - at least one evaluation device (142), wherein the evaluation device (142) is designed to generate at least one item of information on a transversal position of the object (112) by evaluating the transversal sensor signal and to generate at least one item of information
20 on a longitudinal position of the object (112) by evaluating the longitudinal sensor signal.
2. The detector (110) according to the preceding claim, wherein the transversal optical sensor (130) is a photo detector having at least one first electrode (160), at least one second electrode (170) and at least one photovoltaic material (164, 166, 168), wherein the
25 photovoltaic material (164, 166, 168) is embedded in between the first electrode (160) and the second electrode (170), wherein the photovoltaic material (164, 166, 168) is adapted to generate electric charges in response to an illumination of the photovoltaic material (164, 166, 168) with light, wherein the second electrode (170) is a split electrode having at least two partial electrodes (176), wherein the transversal optical sensor (130) has a
30 sensor region (136), wherein the at least one transversal sensor signal indicates a position of the light beam (138) in the sensor region (136).
3. The detector (110) according to the preceding claim, wherein electrical currents through the partial electrodes (176) are dependent on a position of the light beam (138) in the
35 sensor region (136), wherein the transversal optical sensor (130) is adapted to generate the transversal sensor signal in accordance with the electrical currents through the partial electrodes (176).
4. The detector (110) according to the preceding claim, wherein the detector (110) is
40 adapted to derive the information on the transversal position of the object (112) from at least one ratio of the currents through the partial electrodes (176).

5. The detector (110) according to any of the three preceding claims, wherein the photo detector is a dye-sensitized solar cell.
- 5 6. The detector (110) according to any of the four preceding claims, wherein the first electrode (160) at least partially is made of at least one transparent conductive oxide, wherein the second electrode (170) at least partially is made of an electrically conductive polymer (188), preferably a transparent electrically conductive polymer (188).
- 10 7. The detector (110) according to any of the preceding claims, wherein at least one of the transversal optical sensor (130) and the longitudinal optical sensor (132) is a transparent optical sensor.
- 15 8. The detector (110) according to any of the preceding claims, wherein the transversal optical sensor (130) and the longitudinal optical sensor (132) are stacked along the optical axis (116) such that a light beam (138) travelling along the optical axis (116) both impinges on the transversal optical sensor (130) and on the longitudinal optical sensor (132).
- 20 9. The detector (110) according to any of the preceding claims, wherein the longitudinal optical sensor (132) comprises at least one dye-sensitized solar cell.
- 25 10. The detector (110) according to the preceding claim, wherein the longitudinal optical sensor (132) comprises at least one first electrode (160), at least one n-semiconducting metal oxide (164), at least one dye (166), at least one p-semiconducting organic material (168), preferably a solid p-semiconducting organic material (168), and at least one second electrode (170).
- 30 11. The detector (110) according to the preceding claim, wherein both the first electrode (160) and the second electrode (170) are transparent.
- 35 12. The detector (110) according to any of the preceding claims, wherein the evaluation device (142) is designed to generate the at least one item of information on the longitudinal position of the object (112) from at least one predefined relationship between the geometry of the illumination and a relative positioning of the object (112) with respect to the detector (110).
13. The detector (110) according to any of the preceding claims, furthermore comprising at least one illumination source (192).
- 40 14. The detector (110) according to any of the preceding claims, wherein the detector (110) has a plurality of longitudinal optical sensors (132), wherein the longitudinal optical sensors (132) are stacked.

15. The detector (110) according to the preceding claim, wherein the longitudinal optical sensors (132) are arranged such that a light beam (138) from the object (112) illuminates all longitudinal optical sensors (132), wherein at least one longitudinal sensor signal is generated by each longitudinal optical sensor (132), wherein the evaluation device (142) is adapted to normalize the longitudinal sensor signals and to generate the information on the longitudinal position of the object (112) independent from an intensity of the light beam (138).
16. The detector (110) according to any of the two preceding claims, wherein a last longitudinal optical sensor (144) is arranged in a manner that the light beam (138) illuminates all other longitudinal optical sensors (132) apart from the last longitudinal optical sensor (144), until the light beam (138) impinges on the last longitudinal optical sensor (144), wherein the last longitudinal optical sensor (144) is intransparent with respect to the light beam (138).
17. The detector (110) according to any of the three preceding claims, wherein the stack of at least two optical sensors is partially or fully be immersed in an oil, in a liquid and/or in a solid material.
18. The detector (110) according to any of the preceding claims, wherein the at least one transversal optical sensor and/or the at least one longitudinal optical sensor uses at least two different transparent substrates.
19. The detector (110) according to any of the preceding claims, wherein the detector (110) further comprises at least one imaging device (157).
20. The detector (110) according to any of the preceding claims, wherein the detector (110) further comprises at least one optically sensitive element (159).
21. The detector (110) according to any of the preceding claims, wherein the optically sensitive element (161) comprises a color wheel (163), a color drum, and/or a filter wheel using an elliptically polarizing filter.
22. The detector (110) according to any of the preceding claims, wherein the evaluation device (142) is adapted to generate the at least one item of information on the longitudinal position of the object (112) by determining a diameter of the light beam (138) from the at least one longitudinal sensor signal.
23. The detector (110) according to the preceding claim, wherein the evaluation device (142) is adapted to compare the diameter of the light beam (138) with known beam properties of

the light beam (138) in order to determine the at least one item of information on the longitudinal position of the object (112).

24. The detector (110) according to any of the preceding claims, wherein the longitudinal optical sensor (132) is furthermore designed in such a way that the longitudinal sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination.
25. A human-machine interface (196) for exchanging at least one item of information between a user (200) and a machine, wherein the human-machine interface (196) comprises at least one detector (110) according to any of the preceding claims relating to a detector (110), wherein the human-machine interface (196) is designed to generate at least one item of geometrical information of the user (200) by means of the detector (110) wherein the human-machine interface (196) is designed to assign to the geometrical information at least one item of information.
26. An entertainment device (198) for carrying out at least one entertainment function, wherein the entertainment device (198) comprises at least one human-machine interface (196) according to any of the preceding claims referring to a human-machine interface (196), wherein the entertainment device (198) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (196), wherein the entertainment device (198) is designed to vary the entertainment function in accordance with the information.
27. A tracking system (199) for tracking the position of at least one movable object (112), the tracking system (199) comprising at least one detector (110) according to any of the preceding claims referring to a detector (110), the tracking system (199) further comprising at least one track controller (201), wherein the track controller (201) is adapted to track a series of positions of the object (112), each position comprising at least one item of information on a transversal position of the object (112) at a specific point in time and at least one item of information on a longitudinal position of the object (112) at a specific point in time.
28. A camera (111) for imaging at least one object (112), the camera (111) comprising at least one detector (110) according to any one of the preceding claims referring to a detector (110).
29. A method for determining a position of at least one object (112),
- wherein at least one transversal optical sensor (130) of a detector (110) is used, wherein the transversal optical sensor (130) determines a transversal position of at least one light beam (138) traveling from the object (112) to the detector (110), the transversal position being a position in at least one dimension perpendicular to an optical axis (116) of the

detector (110), wherein the transversal optical sensor (130) generates at least one transversal sensor signal;

- wherein at least one longitudinal optical sensor (132) of the detector (110) is used, wherein the longitudinal optical sensor (132) has at least one sensor region (136), wherein the longitudinal optical sensor (132) generates at least one longitudinal sensor signal in a manner dependent on an illumination of the sensor region (136) by the light beam (138), wherein the longitudinal sensor signal, given the same total power of the illumination, is dependent on a beam cross-section of the light beam (138) in the sensor region (136);
- wherein at least one evaluation device (142) is used, wherein the evaluation device (142) generates at least one item of information on a transversal position of the object (112) by evaluating the transversal sensor signal and wherein the evaluation device (142) further generates at least one item of information on a longitudinal position of the object (112) by evaluating the longitudinal sensor signal.

30. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use, selected from the group consisting of: a distance measurement, in particular in traffic technology; a position measurement, in particular in traffic technology; a tracking application, in particular in traffic technology.

31. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use as an entertainment application.

32. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use as a camera (111), in particular in a security application.

33. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use as a human-machine interface (196) application.

34. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use as a mapping application, in particular for generating maps of at least one space.

35. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use in automated machine processes, selected from the group consisting of: a distance measurement; a position measurement; a tracking application.

36. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use in high-precision metrology, in particular in analytics.

37. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use in modeling of manufacturing parts.
 38. The use of a detector (110) according to any of the preceding claims relating to a detector (110), for a purpose of use in medical operations, in particular in endoscopic methods.

Detector for optically detecting at least one object

Description

5 Field of the invention

The invention relates to a detector, a detector system and a method for determining a position of at least one object. The invention further relates to a human-machine interface for exchanging at least one item of information between a user and a machine, an entertainment device, a tracking system, a camera, a scanning system and various uses of the detector device. The devices, systems, methods and uses according to the present invention specifically may be employed for example in various areas of daily life, gaming, traffic technology, production technology, security technology, photography such as digital photography or video photography for arts, documentation or technical purposes, medical technology or in the sciences. Further, the invention specifically may be used for scanning one or more objects and/or for scanning a scenery, such as for generating a depth profile of an object or of a scenery, e.g. in the field of architecture, metrology, archaeology, arts, medicine, engineering or manufacturing. However, other applications are also possible.

20 Prior art

A large number of optical sensors and photovoltaic devices are known from the prior art. While photovoltaic devices are generally used to convert electromagnetic radiation, for example, ultra-violet, visible or infrared light, into electrical signals or electrical energy, optical detectors are generally used for picking up image information and/or for detecting at least one optical parameter, for example, a brightness.

A large number of optical sensors which can be based generally on the use of inorganic and/or organic sensor materials are known from the prior art. Examples of such sensors are disclosed in US 2007/0176165 A1, US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1, US 2007/0176165 A1, WO 2009/013282 A1, WO 2012/110924 A1, WO 2014/097181 A1, WO 2015/024871 A1, US 4,767,211, WO 2014/198629 A1, WO 2014/198626 A1, WO 2014/198629 A1 and WO 2014/198625 A1, the full content of which is herewith included by reference. Further, referring to potential materials and optical sensors which may also be employed in the context of the present invention, reference may be made to European patent applications EP 15 153 215.7, filed on January 30, 2015, EP 15 157 363.1, filed on March 3, 2015, EP 15 164 653.6, filed on April 22, 2015, EP 15177275.3, filed on July 17, 2015, EP 15180354.1 and EP 15180353.3, both filed on August 10, 2015, and EP 15 185 005.4, filed on September 14, 2015, EP 15 196 238.8 and EP 15 196 239.6, both filed on November 25, 2015, EP 15 197 744.4, filed on December 3, 2015, the full content of all of which is herewith also included by reference.

Further, reference may be made to detector concepts comparing signals of at least two different sources for determining a position of an object. Thus, as an example, reference may be made to EP 16155834.1, EP 16155835.8 or EP 16155845.7, all filed on February 16, 2016, the full

disclosure of which is herewith included by reference. Further, P. Bartu, R. Koeppe, N. Arnold, A. Neulinger, L. Fallon, and S. Bauer, Conformable large-area position-sensitive photodetectors based on luminescence collecting silicone waveguides, J. Appl. Phys. 107, 123101 (2010), describe a kind of position sensitive detector (PSD) device which might be suitable for large areas and on curved surfaces.

For example, US 5,323,222 A describes a distance measuring device contains a light-projecting section for projecting luminous flux onto a subject. A light-receiving section is placed the base length away from the light-projecting section, receives the reflected rays of light from the subject, and produces a photoelectric current according to the amount of light received. The light-receiving section is divided into at least four light-receiving elements by a first dividing line that crosses the base length at right angles and by a second dividing line that crosses the first dividing line obliquely. A first ratio calculating section calculates the ratio of the sum of the photoelectric currents generated by the light-receiving elements on one side of the first dividing line to the sum of the photoelectric currents produced by the light-receiving elements on the other side. A second ratio calculating section calculates the ratio of the sum of the photoelectric currents generated by the light-receiving elements on one side of the second dividing line to the sum of the photoelectric currents produced by the light-receiving elements on the other side. A distance-determining section calculates the sum of the outputs of the first and second ratio calculating sections, and based on the resulting value, determines the distance from the device to the subject.

US 4,675,517 A describes a photosensitive element having first and second sensitive regions arranged to receive a light spot in such a way that as the light spot lies astride the boundary there between, the ratio of the areas of the two parts of the spot light which are received by the first and second sensitive regions, respectively, varies depending on the received position of the light spot, whereby the received position of the light spot is detected from the variation of the ratio of the outputs of the first and second sensitive regions, wherein an error of variation of the ratio of the outputs of the first and second sensitive regions for the received position of the light spot, which takes place when the diameter of the received spot light is so large as to overrun the first and second sensitive regions, is corrected by providing a supplementary sensitive region surrounding the first or second sensitive region.

WO 2015/024871 A1 describes an optical detector. The optical detector comprising: - at least one spatial light modulator being adapted to modify at least one property of a light beam in a spatially resolved fashion, having a matrix of pixels, each pixel being controllable to individually modify the at least one optical property of a portion of the light beam passing the pixel; - at least one optical sensor adapted to detect the light beam after passing the matrix of pixels of the spatial light modulator and to generate at least one sensor signal; - at least one modulator device adapted for periodically controlling at least two of the pixels with different modulation frequencies; and - at least one evaluation device adapted for performing a frequency analysis in order to determine signal components of the sensor signal for the modulation frequencies.

However, determination of distance to an object using these known methods and devices depends on the object size. In particular, the optical sensors may show a luminance dependency which renders the evaluation of the measurement result more difficult, and, additionally, may dependent on a target spot size. Dependency on object size may result in susceptibility of distance determination on manufacturing tolerances and environmental conditions. Furthermore, these methods and devices require a large baseline, and thus, large dimensions in order to reach a reliable distance value.

10 Problem addressed by the invention

It is therefore an object of the present invention to provide devices and methods facing the above-mentioned technical challenges of known devices and methods. Specifically, it is an object of the present invention to provide devices and methods which reliably may determine a position of an object in space, preferably with a low technical effort and with low requirements in terms of technical resources and cost.

Summary of the invention

20 This problem is solved by the invention with the features of the independent patent claims. Advantageous developments of the invention, which can be realized individually or in combination, are presented in the dependent claims and/or in the following specification and detailed embodiments.

25 As used in the following, the terms "have", "comprise" or "include" or any arbitrary grammatical variations thereof are used in a non-exclusive way. Thus, these terms may both refer to a situation in which, besides the feature introduced by these terms, no further features are present in the entity described in this context and to a situation in which one or more further features are present. As an example, the expressions "A has B", "A comprises B" and "A includes B" may both refer to a situation in which, besides B, no other element is present in A (i.e. a situation in which A solely and exclusively consists of B) and to a situation in which, besides B, one or more further elements are present in entity A, such as element C, elements C and D or even further elements.

35 Further, it shall be noted that the terms "at least one", "one or more" or similar expressions indicating that a feature or element may be present once or more than once typically will be used only once when introducing the respective feature or element. In the following, in most cases, when referring to the respective feature or element, the expressions "at least one" or "one or more" will not be repeated, non-withstanding the fact that the respective feature or element may be present once or more than once.

Further, as used in the following, the terms "preferably", "more preferably", "particularly", "more particularly", "specifically", "more specifically" or similar terms are used in conjunction with op-

tional features, without restricting alternative possibilities. Thus, features introduced by these terms are optional features and are not intended to restrict the scope of the claims in any way. The invention may, as the skilled person will recognize, be performed by using alternative features. Similarly, features introduced by "in an embodiment of the invention" or similar expressions are intended to be optional features, without any restriction regarding alternative embodiments of the invention, without any restrictions regarding the scope of the invention and without any restriction regarding the possibility of combining the features introduced in such a way with other optional or non-optional features of the invention.

In a first aspect of the present invention a detector for determining a position of at least one object is disclosed. As used herein, the term "object" refers to a point or region emitting at least one light beam. The light beam may originate from the object, such as by the object and/or at least one illumination source integrated or attached to the object emitting the light beam, or may originate from a different illumination source, such as from an illumination source directly or indirectly illuminating the object, wherein the light beam is reflected or scattered by the object. As used herein, the term "position" refers to at least one item of information regarding a location and/or orientation of the object and/or at least one part of the object in space. Thus, the at least one item of information may imply at least one distance between at least one point of the object and the at least one detector. As will be outlined in further detail below, the distance may be a longitudinal coordinate or may contribute to determining a longitudinal coordinate of the point of the object. Additionally or alternatively, one or more other items of information regarding the location and/or orientation of the object and/or at least one part of the object may be determined. As an example, additionally, at least one transversal coordinate of the object and/or at least one part of the object may be determined. Thus, the position of the object may imply at least one longitudinal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one transversal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one orientation information of the object, indicating an orientation of the object in space.

The detector comprises:

- at least one transfer device, wherein the transfer device has at least one focal length in response to at least one incident light beam propagating from the object to the detector;
- at least two optical sensors, wherein each optical sensor has at least one light sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by the light beam,
- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating a quotient signal Q from the sensor signals.

The detector may be adapted to determine the longitudinal coordinate z of the object in at least one measurement range independent from the object size in an object plane.

As used herein, an “optical sensor” generally refers to a light-sensitive device for detecting a light beam, such as for detecting an illumination and/or a light spot generated by at least one light beam. As further used herein, a “light-sensitive area” generally refers to an area of the optical sensor which may be illuminated externally, by the at least one light beam, in response to which illumination the at least one sensor signal is generated. The light-sensitive area may specifically be located on a surface of the respective optical sensor. Other embodiments, however, are feasible. As used herein, the term “at least two optical sensors each having at least one light sensitive area” refers to configurations with two single optical sensors each having one light sensitive area and to configurations with one combined optical sensor having at least two light sensitive areas. Thus, the term “optical sensor” furthermore refers to a light-sensitive device configured to generate one output signal, whereas, herein, a light-sensitive device configured to generate two or more output signals, for example at least one CCD and/or CMOS device, is referred to as two or more optical sensors. As will further be outlined in detail below, each optical sensor may be embodied such that precisely one light-sensitive area is present in the respective optical sensor, such as by providing precisely one light-sensitive area which may be illuminated, in response to which illumination precisely one uniform sensor signal is created for the whole optical sensor. Thus, each optical sensor may be a single area optical sensor. The use of the single area optical sensors, however, renders the setup of the detector specifically simple and efficient. Thus, as an example, commercially available photo-sensors, such as commercially available silicon photodiodes, each having precisely one sensitive area, may be used in the set-up. Other embodiments, however, are feasible. Thus, as an example, an optical device comprising two, three, four or more than four light-sensitive areas may be used which is regarded as two, three, four or more than four optical sensors in the context of the present invention. As an example, the optical device may comprise a matrix of light-sensitive areas. Thus, as an example, the optical sensors may be part of or constitute a pixelated optical device. As an example, the optical sensors may be part of or constitute at least one CCD and/or CMOS device having a matrix of pixels, each pixel forming a light-sensitive area.

As further used herein, a “sensor signal” generally refers to a signal generated by an optical sensor in response to the illumination by the light beam. Specifically, the sensor signal may be or may comprise at least one electrical signal, such as at least one analogue electrical signal and/or at least one digital electrical signal. More specifically, the sensor signal may be or may comprise at least one voltage signal and/or at least one current signal. More specifically, the sensor signal may comprise at least one photocurrent. Further, either raw sensor signals may be used, or the detector, the optical sensor or any other element may be adapted to process or preprocess the sensor signal, thereby generating secondary sensor signals, which may also be used as sensor signals, such as preprocessing by filtering or the like.

The light-sensitive areas specifically may be oriented towards the object. As used herein, the term “is oriented towards the object” generally refers to the situation that the respective surfaces

of the light-sensitive areas are fully or partially visible from the object. Specifically, at least one interconnecting line between at least one point of the object and at least one point of the respective light-sensitive area may form an angle with a surface element of the light-sensitive area which is different from 0° , such as an angle in the range of 20° to 90° , preferably 80° to 90° such as 90° . Thus, when the object is located on the optical axis or close to the optical axis, the light beam propagating from the object towards the detector may be essentially parallel to an optical axis. As used herein, the term “essentially perpendicular” refers to the condition of a perpendicular orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less. Similarly, the term “essentially parallel” refers to the condition of a parallel orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less.

The light beam may propagate from the object towards the detector. As will be outlined in further detail below, the light beam may originate from the object, such as by the object and/or at least one illumination source integrated or attached to the object emitting the light beam, or may originate from a different illumination source, such as from an illumination source directly or indirectly illuminating the object, wherein the light beam is reflected or scattered by the object and, thereby, is at least partially directed towards the detector. The illumination source, as an example, may be or may comprise one or more of an external illumination source, an illumination source integrated into the detector or an illumination source integrated into a beacon device being one or more of attached to the object, integrated into the object or held by the object. Thus, the detector may be used in active and/or passive illumination scenarios. For example, the illumination source may be adapted to illuminate the object, for example, by directing a light beam towards the object, which reflects the light beam. Additionally or alternatively, the object may be adapted to generate and/or to emit the at least one light beam. The light source may be or may comprise at least one multiple beam light source. For example, the light source may comprise at least one laser source and one or more diffractive optical elements (DOEs).

As used herein, the term “ray” generally refers to a line that is perpendicular to wavefronts of light which points in a direction of energy flow. As used herein, the term “beam” generally refers to a collection of rays. In the following, the terms “ray” and “beam” will be used as synonyms. As further used herein, the term “light beam” generally refers to an amount of light, specifically an amount of light traveling essentially in the same direction, including the possibility of the light beam having a spreading angle or widening angle. The light beam may have a spatial extension. Specifically, the light beam may have a non-Gaussian beam profile. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile. The trapezoid beam profile may have a plateau region and at least one edge region. As used herein, the term “beam profile” generally refers to a transverse intensity profile of the light beam. The light beam specifically may be a Gaussian light beam or a linear combination of Gaussian light beams, as will be outlined in further detail below. Other embodiments are feasible, however. The transfer device may be configured for one or more of adjusting, defining and determining the beam profile, in particular a shape of the beam profile.

The light beam may be a monochromatic light beam. The light beam may comprise a narrow band of wavelengths, preferably the light beam may comprise a single wavelength. The at least one light source may be adapted to generate at least one monochromatic light beam and/or the detector may comprise at least one filter element adapted to filter a narrow band of wavelength, such as a monochromator.

The illumination source may be adapted to generate at least one illumination pattern for illuminating the object. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. The detector may be configured such that the illumination pattern propagates from the detector, in particular from at least one opening of the housing, towards the object along and/or parallel to an optical axis of the detector. For this purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illumination pattern such that it propagates along or parallel to the optical axis. Specifically, the illumination source may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. As used herein, the term "pattern" refers to an arbitrary known or pre-determined arrangement comprising at least one arbitrarily shaped feature. The pattern may comprise at least one feature such as a point or symbol. The pattern may comprise a plurality of features. The pattern may comprise an arrangement of periodic or non-periodic features. As used herein, the term "illumination pattern" refers to a pattern which illuminates the object. The illumination pattern may be generated by ambient light, such as by at least one ambient light source, or by the at least one illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern, a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines; at least one fringe pattern. For example, the illumination source may be adapted to generate and/or to project a cloud of points. The illumination pattern may comprise regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern, or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that a hexagonal pattern may be preferred. A distance between two features of the illumination pattern and/or an area of the at least one illumination feature may depend on the circle of confusion in the image.

The illumination source may comprise one or more of at least one light projector; at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The illumination source may comprise at least one light source adapted to generate the illumination pattern directly. For example, the illumination source may comprise at least one laser source. For example, the illumination source may com-

prise at least one line laser. The line laser may be adapted to send a laser line to the object, for example a horizontal or vertical laser line. The illumination source may comprise a plurality of line lasers. For example, the illumination source may comprise at least two line lasers which may be arranged such that the illumination pattern comprises at least two parallel or crossing
5 lines. The illumination source may comprise the at least one light projector adapted to generate a cloud of points such that the illumination pattern may comprise a plurality of point pattern. The illumination source may comprise at least one mask adapted to generate the illumination pattern from at least one light beam generated by the illumination source. The illumination source may be one of attached to or integrated into a mobile device such as a smartphone. The illumination
10 source may be used for further functions that may be used in determining an image such as for an autofocus function. The illumination source may be attached to a mobile device such as by using a connector such as a USB- or phone-connector such as the headphone jack.

The illumination source may be adapted to generate pulsed illumination. The illumination source
15 may be adapted to generate at least one light pulse. As used herein, the term "light pulse" or "pulsed illumination" refers to a light beam limited in time. The light pulse may have a pre-defined length or time duration, for example in the nanoseconds range. For example, the illumination source may be adapted to generate pulses with a pulse length of less than a nanosecond, such as a tenth of a nanosecond, up to a tenth of a second. The illumination source may
20 be adapted to periodically generate the light pulse. For example, the illumination source may be adapted to generate the light pulse with a frequency of 10 Hz to 10 GHz.

The illumination source may be adapted to generate a pulsed light beam. For example, the illumination source may be adapted to generate a continuous illumination light beam and the de-
25 tector may comprise at least one interruption device adapted to interrupt the illumination, in particular periodically. The interruption device may comprise at least one shutter and/or a beam chopper or some other type of mechanical or electronical periodic beam interrupting device, for example comprising at least one interrupter blade or interrupter wheel, which preferably rotates at constant speed and which can thus periodically interrupt the illumination. By way of example,
30 the at least one interruption device can also be wholly or partly integrated into the illumination source. Various possibilities are conceivable.

The optical sensors may be sensitive in one or more of the ultraviolet, the visible or the infrared spectral range. Specifically, the optical sensors may be sensitive in the visible spectral range
35 from 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm. Specifically, the optical sensors may be sensitive in the near infrared region. Specifically, the optical sensors may be sensitive in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm. The optical sensors, specifically, may be sensitive in the infrared spectral range, specifically in the range of 780 nm to 3.0 microme-
40 ters. For example, the optical sensors each, independently, may be or may comprise at least one element selected from the group consisting of a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. For example, the optical sensors may be or may comprise at least one element selected from the group consisting of a CCD sensor element, a

CMOS sensor element, a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. Any other type of photosensitive element may be used. As will be outlined in further detail below, the photosensitive element generally may fully or partially be made of inorganic materials and/or may fully or partially be made of organic materials. Most commonly, as will be outlined in further detail below, one or more photodiodes may be used, such as commercially available photodiodes, e.g. inorganic semiconductor photodiodes. As further used herein, the term "photosensitive element" generally refers to an element which is sensitive against illumination in one or more of the ultraviolet, the visible or the infrared spectral range. Specifically, the photosensitive element may be or may comprise at least one element selected from the group consisting of a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. Any other type of photosensitive element may be used.

In view of the technical challenges involved in the prior art documents discussed above, specifically in view of the technical effort which is required for generating the so called FiP effect as described in WO 2015/024871 it has to be noted that the present invention specifically may be realized by using non-FiP optical sensors. In fact, since optical sensors having the FiP characteristic typically exhibit a strong peak in the respective sensor signals at a focal point, the range of measurement of a detector according to the present invention using FiP sensors as optical sensors may be limited to a range in between the two positions and which the first and second optical sensors are in focus of the light beam. When using linear optical sensors, however, i.e. optical sensors not exhibiting the FiP effect, this problem, with the setup of the present invention, generally may be avoided. Consequently, the first and second optical sensor may each have, at least within a range of measurement, a linear signal characteristic such that the respective first and second sensor signals may be dependent on the total power of illumination of the respective optical sensor and may be independent from a diameter of a light spot of the illumination. It shall be noted, however, that other embodiments are feasible, too.

The first and second optical sensors each specifically may be semiconductor sensors, preferably inorganic semiconductor sensors, more preferably photodiodes and most preferably silicon photodiodes. Thus, as opposed to complex and expensive FiP sensors, the present invention simply may be realized by using commercially available inorganic photodiodes, i.e. one small photodiode and one large area photodiode. Thus, the setup of the present invention may be realized in a cheap and inexpensive fashion.

However, embodiments are feasible in which the detector may comprise at least one FiP sensor adapted for generating the so called FiP effect as described in WO 2015/024871, as will be outlined in detail below.

The detector may further comprise at least one illumination source for illuminating the object. As an example, the illumination source may be configured for generating an illuminating light beam for illuminating the object. The detector may be configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector. For this

purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

The illumination source, specifically, may be configured for emitting light in the infrared spectral range. It shall be noted, however, that other spectral ranges are feasible, additionally or alternatively. Further, the illumination source, as outlined above, specifically may be configured for emitting modulated or non-modulated light. In case a plurality of illumination sources is used, the different illumination sources may have different modulation frequencies which, as outlined in further detail below, later on may be used for distinguishing the light beams. The illumination source may be adapted to generate and/or to project a cloud of points, for example the illumination source may comprise one or more of at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources.

Specifically, the illumination source may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The illumination source may be adapted to generate and/or to project a cloud of points, for example the illumination source may comprise one or more of at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The illumination source and the optical sensors may be arranged in a common plane or in different planes. The illumination source and the optical sensors may have different spatial orientation. In particular, the illumination source and the optical sensors may be arranged in a twisted arrangement.

The illuminating light beam generally may be parallel to the optical axis or tilted with respect to the optical axis, e.g. including an angle with the optical axis. As an example, the illuminating light beam, such as the laser light beam, and the optical axis may include an angle of less than 10° , preferably less than 5° or even less than 2° . Other embodiments, however, are feasible. Further, the illuminating light beam may be on the optical axis or off the optical axis. As an example, the illuminating light beam may be parallel to the optical axis having a distance of less than 10 mm to the optical axis, preferably less than 5 mm to the optical axis or even less than 1 mm to the optical axis or may even coincide with the optical axis.

The detector comprises at least one transfer device. The term "transfer device", also denoted as "transfer system", may generally refer to one or more optical elements which are adapted to modify the light beam, such as by modifying one or more of a beam parameter of the light beam, a width of the light beam or a direction of the light beam. The transfer device may be adapted to guide the light beam onto the optical sensors. The transfer device specifically may comprise one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one aspheric lens; at least one diffractive optical

element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

- 5 As used herein, the term “focal length” of the transfer device refers to a distance over which incident collimated rays which may impinge the transfer device are brought into a “focus” which may also be denoted as “focal point”. Thus, the focal length constitutes a measure of an ability of the transfer device to converge an impinging light beam. Thus, the transfer device may comprise one or more imaging elements which can have the effect of a converging lens. By way of
10 example, the transfer device can have one or more lenses, in particular one or more refractive lenses, and/or one or more convex mirrors. In this example, the focal length may be defined as a distance from the center of the thin refractive lens to the principal focal points of the thin lens. For a converging thin refractive lens, such as a convex or biconvex thin lens, the focal length may be considered as being positive and may provide the distance at which a beam of collimat-
15 ed light impinging the thin lens as the transfer device may be focused into a single spot. Additionally, the transfer device can comprise at least one wavelength-selective element, for example at least one optical filter. Additionally, the transfer device can be designed to impress a pre-defined beam profile on the electromagnetic radiation, for example, at the location of the sensor region and in particular the sensor area. The abovementioned optional embodiments of the
20 transfer device can, in principle, be realized individually or in any desired combination.

- The transfer device may have an optical axis. In particular, the detector and the transfer device have a common optical axis. As used herein, the term “optical axis of the transfer device” generally refers to an axis of mirror symmetry or rotational symmetry of the lens or lens system. The
25 optical axis of the detector may be a line of symmetry of the optical setup of the detector. The detector comprises at least one transfer device, preferably at least one transfer system having at least one lens. The transfer system, as an example, may comprise at least one beam path, with the elements of the transfer system in the beam path being located in a rotationally symmetrical fashion with respect to the optical axis. Still, as will also be outlined in further detail below, one or more optical elements located within the beam path may also be off-centered or
30 tilted with respect to the optical axis. In this case, however, the optical axis may be defined sequentially, such as by interconnecting the centers of the optical elements in the beam path, e.g. by interconnecting the centers of the lenses, wherein, in this context, the optical sensors are not counted as optical elements. The optical axis generally may denote the beam path. Therein, the
35 detector may have a single beam path along which a light beam may travel from the object to the optical sensors, or may have a plurality of beam paths. As an example, a single beam path may be given or the beam path may be split into two or more partial beam paths. In the latter case, each partial beam path may have its own optical axis and the condition noted above generally may refer to each beam path independently.. The optical sensors may be located in one
40 and the same beam path or partial beam path. Alternatively, however, the optical sensors may also be located in different partial beam paths. In case the optical sensors are distributed over different partial beam paths, the above-mentioned condition may be described such that at least one first optical sensor is located in at least one first partial beam path, being offset from the

optical axis of the first partial beam path by a first spatial offset, and at least one second optical sensor is located in at least one second partial beam path, being offset from the optical axis of the second partial beam path by at least one second spatial offset, wherein the first spatial offset and the second spatial offset are different.

5

The transfer device may constitute a coordinate system, wherein a longitudinal coordinate l is a coordinate along the optical axis and wherein d is a spatial offset from the optical axis. The coordinate system may be a polar coordinate system in which the optical axis of the transfer device forms a z -axis and in which a distance from the z -axis and a polar angle may be used as additional coordinates. A direction parallel or antiparallel to the z -axis may be considered a longitudinal direction, and a coordinate along the z -axis may be considered a longitudinal coordinate l . Any direction perpendicular to the z -axis may be considered a transversal direction, and the polar coordinate and/or the polar angle may be considered a transversal coordinate.

10

15

The optical sensors may be positioned off focus. As used herein, the term “focus” generally refers to one or both of a minimum extend of a circle of confusion of the light beam, in particular of at least one light beam emitted from one point of the object, caused by the transfer device or a focal length of the transfer device. As used herein, the term “circle of confusion” refers to a light spot caused by a cone of light rays of the light beam focused by the transfer device. The circle of confusion may depend on a focal length f of the transfer device, a longitudinal distance from the object to the transfer device, a diameter of an exit pupil of the transfer device, a longitudinal distance from the transfer device to the light sensitive area, a distance from the transfer device to an image of the object. For example, for Gaussian beams, a diameter of the circle of confusion may be a width of the Gaussian beam. In particular, for a point like object situated or placed at infinite distance from the detector the transfer device may be adapted to focus the light beam from the object into a focus point at the focal length of the transfer device. For non-point like objects situated or placed at infinite distance from the detector the transfer device may be adapted to focus the light beam from at least one point of the object into a focus plane at the focal length of the transfer device. For point like objects not situated or placed at infinite distance from the detector, the circle of confusion may have a minimum extend at least at one longitudinal coordinate. For non-point like objects not situated or placed at infinite distance from the detector, the circle of confusion of the light beam from at least one point of the object may have a minimum extend at least at one longitudinal coordinate. As used herein, the term “positioned off focus” generally refers to a position other than the minimum extent of a circle of confusion of the light beam caused by the transfer device or a focal length of the transfer device. In particular, the focal point or minimum extend of the circle of confusion may be at a longitudinal coordinate l_{focus} , whereas the position of each of the optical sensors may have a longitudinal coordinate l_{sensor} different from l_{focus} . For example, the longitudinal coordinate l_{sensor} may be, in a longitudinal direction, arranged closer to the position of the transfer device than the longitudinal coordinate l_{focus} or may be arranged further away from the position of the transfer device than the longitudinal coordinate l_{focus} . Thus, the longitudinal coordinate l_{sensor} and the longitudinal coordinate l_{focus} may be situated at different distances from the transfer device. For example, the optical sensors may be spaced apart from the minimum extend of the circle of confusion in longitu-

20

25

30

35

40

dinal direction by $\pm 2\%$ of focal length, preferably by $\pm 10\%$ of focal length, most preferably $\pm 20\%$ of focal length. For example, at a focal length of the transfer device may be 20mm and the longitudinal coordinate l_{sensor} may be 19,5 mm, i.e. the sensors may be positioned at 97,5% focal length, such that l_{sensor} is spaced apart from the focus by 2,5% of focal length.

- 5 The optical sensors may be arranged such that the light-sensitive areas of the optical sensors differ in at least one of: their longitudinal coordinate, their spatial offset, or their surface areas.

Each light-sensitive area may have a geometrical center. As used herein, the term “geometrical center” of an area generally may refer to a center of gravity of the area. As an example, if an
10 arbitrary point inside or outside the area is chosen, and if an integral is formed over the vectors interconnecting this arbitrary point with each and every point of the area, the integral is a function of the position of the arbitrary point. When the arbitrary point is located in the geometrical center of the area, the integral of the absolute value of the integral is minimized. Thus, in other
15 words, the geometrical center may be a point inside or outside the area with a minimum overall or sum distance from all points of the area.

For example, each geometrical center of each light-sensitive area may be arranged at a longitudinal coordinate $l_{\text{center},i}$, wherein i denotes the number of the respective optical sensor. In the case of the detector comprising precisely two optical sensors and in the case of the detector
20 comprising more than two optical sensors, the optical sensors may comprise at least one first optical sensor, wherein the first optical sensor, in particular the geometrical center, being arranged at a first longitudinal coordinate $l_{\text{center},1}$, and at least one second optical sensor, wherein the second optical sensor, in particular the geometrical center, being at a second longitudinal coordinate $l_{\text{center},2}$, wherein the first longitudinal coordinate and the second longitudinal coordi-
25 nate differ. For example, the first optical sensor and the second optical sensor may be located in different planes which are offset in a direction of the optical axis. The first optical sensor may be arranged in front of the second optical sensor. Thus, as an example, the first optical sensor may simply be placed on the surface of the second optical sensor. Additionally or alternatively, the first optical sensor may be spaced apart from the second optical sensor, for example, by no
30 more than five times the square root of a surface area of the first light-sensitive area. Additionally or alternatively, the first optical sensor may be arranged in front of the second optical sensor and may be spaced apart from the second optical sensor by no more than 50 mm, preferably by no more than 15 mm. Relative distance of the first optical sensor and second optical sensor may depend, for example, on focal length or object distance.

35 The longitudinal coordinates of the optical sensors may also be identical, as long as one of the above-mentioned conditions is fulfilled. For example, the longitudinal coordinates of the optical sensors may be identical, but the light-sensitive areas may be spaced apart from the optical axis and/or the surface areas differ.

40 Each geometrical center of each light-sensitive area may be spaced apart from the optical axis of the transfer device, such as the optical axis of the beam path or the respective beam path in which the respective optical sensor is located. The distance, in particular in transversal direc-

tion, between the geometrical center and the optical axis is denoted by the term "spatial offset". In the case of the detector comprising precisely two optical sensors and in the case of the detector comprising more than two optical sensors, the optical sensors may comprise at least one first optical sensor being spaced apart from the optical axis by a first spatial offset and at least one second optical sensor being spaced apart from the optical axis by a second spatial offset, wherein the first spatial offset and the second spatial offset differ. The first and second spatial offsets, as an example, may differ by at least a factor of 1.2, more preferably by at least a factor of 1.5, more preferably by at least a factor of two. The spatial offsets may also be zero or may assume negative values, as long as one of the above-mentioned conditions is fulfilled.

As used herein, the term "surface area" generally refers to both of a shape and a content of at least one light-sensitive area. In the case of the detector comprising precisely two optical sensors and in the case of the detector comprising more than two optical sensors, the optical sensors may comprise at least one first optical sensor having a first surface area and at least one second optical sensor having a second surface area. In the case of the detector comprising more than two optical sensors, e.g. a sensor element comprising a matrix of optical sensors, a first group of optical sensors or at least one of the optical sensors of the matrix may form a first surface area, wherein a second group of optical sensors or at least one other optical sensor of the matrix may form a second surface area. The first surface area and the second surface area may differ. In particular, the first surface area and the second surface area are not congruent. Thus, the surface area of the first optical sensor and the second optical sensor may differ in one or more of the shape or content. For example, the first surface area may be smaller than the second surface area. As an example, both the first surface area and the second surface area may have the shape of a square or of a rectangle, wherein side lengths of the square or rectangle of the first surface area are smaller than corresponding side lengths of the square or rectangle of the second surface area. Alternatively, as an example, both the first surface area and the second surface area may have the shape of a circle, wherein a diameter of the first surface area is smaller than a diameter of the second surface area. Again, alternatively, as an example, the first surface area may have a first equivalent diameter, and the second surface area may have a second equivalent diameter, wherein the first equivalent diameter is smaller than the second equivalent diameter. The surface areas may be congruent, as long as one of the above-mentioned conditions is fulfilled.

The optical sensors, in particular the light-sensitive areas, may overlap or may be arranged such that no overlap between the optical sensors is given.

As further used herein, the term "evaluation device" generally refers to an arbitrary device adapted to perform the named operations, preferably by using at least one data processing device and, more preferably, by using at least one processor and/or at least one application-specific integrated circuit. Thus, as an example, the at least one evaluation device may comprise at least one data processing device having a software code stored thereon comprising a number of computer commands. The evaluation device may provide one or more hardware el-

ements for performing one or more of the named operations and/or may provide one or more processors with software running thereon for performing one or more of the named operations.

5 The above-mentioned operations, including determining the at least one longitudinal coordinate of the object, are performed by the at least one evaluation device. Thus, as an example, one or more of the above-mentioned relationships may be implemented in software and/or hardware, such as by implementing one or more lookup tables. Thus, as an example, the evaluation device may comprise one or more programmable devices such as one or more computers, application-specific integrated circuits (ASICs), Field Programmable Gate Arrays (FPGAs), or digital
10 signal processors (DSPs) which are configured to perform the above-mentioned evaluation, in order to determine the at least one longitudinal coordinate of the object. Additionally or alternatively, however, the evaluation device may also fully or partially be embodied by hardware.

15 The evaluation device is configured for determining at least one longitudinal coordinate z of the object by evaluating a quotient signal Q of the sensor signals A as used herein, the term "quotient signal Q " refers to a signal which is generated by combining the sensor signals, in particular by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals. In the following, the quotient signal is also denoted as combined signal or combined sensor signal.

20 The object size may be a priori unknown. An object image size, i.e. the size of the object in the image plane, may be distance dependent. However, different materials may have different scattering properties such that deviations from Lambertian distribution may occur. In particular, a luminance dependence may deviate significantly from a $1/z^2$. In addition, due type of scattering
25 and/or due to reflective properties and/or scattering properties of the object, for example depending on a material of the object, the object image size, in particular diameter of the spot, may vary. Thus, methods and devices using the spot size, for example by counting pixels, or absolute photon numbers for distance determination may be not suitable and may require calibrations depending on the material of the object. Methods and devices adapted for determination
30 of the distance independently from the object size are necessary in order to allow robust distance determination for any materials with one calibration, only. Further, the object size may be altered by the light source itself. For example, the properties of the optics may be altered by one or more of dirt, raindrops, scratches or manufacturing precision of the light source and/or its optics. Thus, the light beam emitted by the light source may be changed in one or more of its
35 properties such as diameter, beam profile, divergence or the like. Thus, methods and devices adapted for determination of the distance independently from the object size are necessary in order to allow robust distance determination for higher manufacturing tolerances or harsher environmental conditions or the like with one calibration, only. Further, object size may be altered depending on temperature as the optical properties of the detector and or the light source may
40 change such as due to a temperature dependent change of the distance between emitter and optics of the light source or due to a temperature dependent change of the distance between sensor and optics of the detector or due to a temperature dependent change of the refracting properties of the lens or the like. Object size independence is, thus, important for measure-

ments with little or no a priori knowledge on one or more of the measured object, the measurement environment, the temperature of the detector and its environment, the manufacturing quality of the sensor and/or the light source. Further, object size independence is, thus, important for measurements that require high flexibility concerning one or more of the measured object, the measurement environment, the temperature of the detector and its environment, the manufacturing quality of the sensor and/or the light source. Further, object size independence is important, when diverging or converging illumination light beams shall be used, such as when diverging or converging laser light beams are used where the size of the illuminated spot changes with distance. Further, object size independence is, thus, important for measurements that require a high robustness in one or more of measurement quality independent of the measured object, the measurement environment, the temperature of the detector and its environment, the manufacturing quality of the sensor and/or the light source.

Known 3D sensing methods are dependent on the object size. For example US 4,675,517 and US 5,323,222 describe devices and methods exhibiting dependence on object size. Specifically, US 4,675,517 describes with respect to Figures 3A to 3C, column 2, line 16 that the distance information changes with spot size. In particular, it is described that in actual practice, with the use of such a system, as the diameter of the image of the reflection of the projected image spot P changes at random, or the optical position deviates, the defined object distance boundaries are caused to shift largely. In particular, problems due to too large spot sizes are addressed. In case the spot size is too large, the sensor is outshined and the resulting ratio is wrong. US 4,675,517 describes to correct this spot size dependence by enlarging the sensor area. However, the spot size dependence is not eliminated. In particular, problems due to too small spot sizes are not addressed. Furthermore, specifically, US 5,323,222 describes that the ratio used for determining the distance depends on a chip size of the light source. In particular, in column 2, line 11 it is outlined that solid lines I1 and I2 in Fig 14A show the relationship between the reciprocal of the distance a and the calculation output $I1/(I1+I2)$ for the light-projecting chip sizes t1 and t2 ($t1 < t2$), respectively. Furthermore, it is described that if the distance between the projection lens and light emitting element is fT, the base length L, and the chip size of the light emitting element t, then the distance measuring range S will be: $S = \infty$ through $fT \cdot L/t$. However, US 5,323,222 does not further address eliminating impact of object size dependence.

As used herein, the term “object size”, generally refers to a size of the object in an object plane, in particular to the size of a spot and/or region and/or the entire object emitting the at least one light beam. As further used herein, the terms “independent from the object size” and “object size independence” refer to the fact that variations of the object size do not influence the determination of the longitudinal coordinate z. As will be outlined in detail below, the quotient signal Q may be used for determining the longitudinal coordinate. Thus, object size independence furthermore refers to the fact that the quotient signal is essentially independent from the object size such that, in case of identical object distance, a first quotient signal determined at a first object size and a second quotient signal determined at a different object size are identical, with a tolerance of $\pm 20\%$ or less, preferably a tolerance of $\pm 10\%$ or less, more preferably a tolerance of $\pm 5\%$ or less. Requirement or condition of object size independence can be stated as follows:

the circle of confusion of at least one light beam emitted from at least one point of the object is greater than an image size of the object, i.e. a size of the object in an image plane. The detector may be adapted to determine the longitudinal coordinate z of the object independent from the object size if the circle of confusion of the at least one light beam emitted from the at least one point of the object is greater than an image size of the object. This condition may be calculated by $O_{size} < \frac{z_0 E_x}{z_i^2} |z_s - z_i|$, wherein z_0 is a longitudinal distance from the object to the transfer device; E_x is a diameter of an exit pupil of the transfer device; z_s is a longitudinal distance from the transfer device to the light sensitive area, z_i is a distance from the transfer device to an image of the object; O_{size} is an object size of the object in the object plane. As used herein, the term “diameter of an exit pupil” refers to an aperture of the transfer device. Given a measurement range the condition can be fulfilled by for example varying the sensor position, the diameter of the exit pupil or the image of the object, for example by varying the focal length. The detector may be adapted to determine the longitudinal coordinate z of the object independent from the object size if $O_{size} < \frac{z_0 E_x}{z_i^2} |z_s - z_i|$ holds true for at least one distance z_0 . For example, the detector may be adapted to determine the longitudinal coordinate z at the at least one distance z_0 if the object size varies and/or changes within a large range, e.g. by more than 100% of the object size. The detector may be adapted to determine the longitudinal coordinate z at distances, at which the above-mentioned condition $O_{size} < \frac{z_0 E_x}{z_i^2} |z_s - z_i|$ is fulfilled only weakly, if the object size varies and/or changes within a smaller range, in particular if the object size varies and/or changes by $\pm 20\%$ or less, preferably by $\pm 10\%$ or less, more preferably by $\pm 5\%$ or less. The detector may be adapted to determine the longitudinal coordinate z over the whole measurement range if $O_{size} < \frac{z_0 E_x}{z_i^2} |z_s - z_i|$ holds true for the at least one distance z_0 and if the object size and if the object size varies and/or changes by $\pm 20\%$ or less, preferably by $\pm 10\%$ or less, more preferably by $\pm 5\%$ or less. As used herein, the term “holds true for at least one distance” refers to that at the at least one distance the longitudinal coordinate z may be determined independent from the object size and that the detector is adapted to determine the longitudinal coordinate z at other distances, in particular within the whole or entire measurement range, if the object size varies and/or changes by $\pm 20\%$ or less, preferably by $\pm 10\%$ or less, more preferably by $\pm 5\%$ or less.

As used herein, the term “measurement range” generally refers to an arbitrary range in which the determination of the longitudinal coordinate z is performed. The measurement range may be adjustable by adjusting one or more parameters selected from the group consisting of: the longitudinal distance from the object to the transfer device z_0 ; the focal length of the transfer device f ; the diameter of the exit pupil of the transfer device E_x ; the longitudinal distance from the transfer device to the light sensitive area z_s , the distance from the transfer device to an image of the object z_i ; the object size O_{size} of the object in the object plane. For example, if the object size does not exceed an object-size limit, a unique relation of the quotient signal Q to the longitudinal distance from the object to the transfer device exists. The object-size limit may depend on the longitudinal distance from the transfer device to the light sensitive area, the longitudinal distance from the object to the transfer device, and an F-number of the transfer device $F\#$, i.e. a ratio of the focal length of the transfer device and the diameter of an exit pupil of the transfer device. For example, the measurement range may be adapted by selecting and/or choosing one or more of the longitudinal distance from the transfer device to the light sensitive area z_s , the dis-

tance from the transfer device to an image of the object z_i , the longitudinal distance from the transfer device to the light sensitive area, the focal length and the F-number of the transfer device. For example, the focal length and/or F-number may be adjusted by using a zoom objective. In particular, the focal length may be between 10 and 200 mm, preferably between 20 and 150 mm. The F-number may be between 1 and 10, preferably between 1,5 and 6. The longitudinal distance from the transfer device may be as short as possible. The longitudinal distance from the transfer device to the light sensitive area may be between 0 and 200 mm, preferably between 20 and 50 mm. For a given system setup (f , $F\#$, z_s) a unique value of the object-size limit can be calculated. For example, in case the focal length is 3,5 mm and the F-number is 2,0, the object size may be smaller than 1,75 mm. Preferably a lower object size limit may be 0.5 μm or more, more preferably 1 μm or more and most preferably 10 μm or more. The lower object size limit refers to a minimum object size using an active measurement system, in particular to a laser spot size.

The evaluation device may be configured for deriving the quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals. The evaluation device may be configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate for determining the longitudinal coordinate. For example, the evaluation device is configured for deriving the quotient signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A_1 and A_2 are areas of the beam profile at the sensor position, and $E(x, y, z_o)$ denotes the beam profile given at the object distance z_o . Area A_1 and area A_2 may differ. In particular, A_1 and A_2 are not congruent. Thus, A_1 and A_2 may differ in one or more of the shape or content. As used herein, the term “beam profile” relates to a spatial distribution, in particular in at least one plane perpendicular to the propagation of the light beam, of an intensity of the light beam. The beam profile may be a cross section of the light beam. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles. Generally the beam profile is dependent on luminance $L(z_o)$ and beam shape $S(x, y; z_o)$, $E(x, y; z_o) = L \cdot S$. Thus, by deriving the quotient signal it may allow determining the longitudinal coordinate independent from luminance. In addition, using the quotient signal allows determination of the distance z_o independent from the object size. Thus, the quotient signal allows determination of the distance z_o independent from the material properties and/or reflective properties and/or scattering properties of the object and independent from alterations of the light source such as by manufacturing precision, heat, water, dirt, damages on the lens, or the like. Further-

more, even at very large spot sizes, for example at an outshining, reliable determination of the longitudinal coordinate of the object may be possible.

Each of the sensor signals may comprise at least one information of at least one area of the beam profile of the light beam. As used herein, the term "area of the beam profile" generally refers to an arbitrary region of the beam profile at the sensor position used for determining the quotient signal Q. The light-sensitive regions may be arranged such that a first sensor signal comprises information of a first area of the beam profile and a second sensor signal comprises information of a second area of the beam profile. The first area of the beam profile and second area of the beam profile may be one or both of adjacent or overlapping regions. The first area of the beam profile and the second area of the beam profile may be not congruent in area.

The evaluation device may be configured to determine and/or to select the first area of the beam profile and the second area of the beam profile. The first area of the beam profile may comprise essentially edge information of the beam profile and the second area of the beam profile may comprise essentially center information of the beam profile. The beam profile may have a center, i.e. a maximum value of the beam profile and/or a center point of a plateau of the beam profile and/or a geometrical center of the light spot, and falling edges extending from the center. The second region may comprise inner regions of the cross section and the first region may comprise outer regions of the cross section. As used herein, the term "essentially center information" generally refers to a low proportion of edge information, i.e. proportion of the intensity distribution corresponding to edges, compared to a proportion of the center information, i.e. proportion of the intensity distribution corresponding to the center. Preferably the center information has a proportion of edge information of less than 10 %, more preferably of less than 5%, most preferably the center information comprises no edge content. As used herein, the term "essentially edge information" generally refers to a low proportion of center information compared to a proportion of the edge information. The edge information may comprise information of the whole beam profile, in particular from center and edge regions. The edge information may have a proportion of center information of less than 10 %, preferably of less than 5%, more preferably the edge information comprises no center content. At least one area of the beam profile may be determined and/or selected as second area of the beam profile if it is close or around the center and comprises essentially center information. At least one area of the beam profile may be determined and/or selected as first area of the beam profile if it comprises at least parts of the falling edges of the cross section. For example, the whole area of the cross section may be determined as first region. The first area of the beam profile may be area A2 and the second area of the beam profile may be area A1.

Other selections of the first area A1 and second area A2 may be feasible. For example, the first area may comprise essentially outer regions of the beam profile and the second area may comprise essentially inner regions of the beam profile. For example, the center signal may be a signal corresponding to a rectangular stripe comprising the center of the light spot. The evaluation device may be adapted to form a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal. In par-

5 ticular, in case of a two-dimensional beam profile, the beam profile may be divided in a left part and a right part, wherein the first area may comprise essentially areas of the left part of the beam profile and the second area may comprise essentially areas of the right part of the beam profile. The first and the second area, as an example, may be adjacent, with a minimum separation from one another. However, the separation between adjacent areas may also be varied such as enlarged to improve the dynamic range of the quotient signal. As an example, the separation between two adjacent areas may be increased by not evaluating the area between the first and the second area. This may reduce the light on one of the areas relative and/or absolute as compared to the adjacent area which will may increase a quotient of the signal of the two
10 areas. Further, one or both of the areas may consist of separated subareas which may be adjacent to each other and/or which may be separated by areas that are not evaluated and/or which may be evaluated as part of a different quotient. Further, the first and the second area may consist of a linear combination of subareas, whereas the signal contributed by each subarea may be weighted differently when forming the center signal and/or the sum signal. This may further
15 be beneficial for increasing the dynamic range of the quotient system.

The extent of the circle of confusion may be larger than the extent of the optical sensor. For example, the optical sensor may be positioned as such that the circle of confusion extends beyond the optical sensor. The optical sensor may thus only partially evaluate the beam profile of
20 the light beam. The evaluation device may be adapted to extrapolate a beam profile such as due to symmetry considerations or due to comparing the partial beam profile to prerecorded beam profiles or the like. Further, the evaluation device may be adapted to evaluate a partial sum signal and a partial center signal of a partial beam profile and convert it into a sum signal and a center signal of an extrapolated and/or fitted and/or prerecorded beam profile or the like.

25 The edge information may comprise information relating to a number of photons in the first area of the beam profile and the center information may comprise information relating to a number of photons in the second area of the beam profile. The evaluation device may be adapted for determining an area integral of the beam profile. The evaluation device may be adapted to determine the edge information by integrating and/or summing of the first area. The evaluation device may be adapted to determine the center information by integrating and/or summing of the
30 second area. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of edge and center signals may be replaced by
35 equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

40 Additionally or alternatively, the evaluation device may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized, for example, by replacing the area integrals in the quotient signal Q by a line integrals along the slice or cut. For improved accuracy, several slices or cuts through the light spot

may be used and averaged. In case of an elliptical spot profile, averaging over several slices or cuts may result in an improved distance information.

The evaluation device may be configured to derive the quotient signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information. Thus, essentially, photon ratios may be used as the physical basis of the method.

The detector may be adapted to determine depth information, in particular absolute depth information, from a radiance ratio of at least two asymmetric regions of a light beam profile on the at least two optical sensors. For example, the detector may comprise a plurality of optical sensors arranged in a matrix. The detector may be adapted to determine depth information from a radiance ratio of at least two asymmetric regions within an enclosed, in particular, a defocused beam profile captured by a single matrix of optical sensors such as a CMOS detector. In particular, the detector may be adapted to determine the depth information using the radiance ratio independent of a certain object size range. This principle is called Distance by Photon Ratio (DPR).

The DPR principle can be applied, for example, to many sub-regions within a segmented image profile, such as a segmented image of at least one feature generated by the at least one light beam on the matrix of optical sensors, which is demonstrated hereafter. The quotient $Q_A(z)$ in the two-dimensional case can be written as

$$Q_A(z) = \frac{\iint_{-r_{out}}^{r_{out}} P(x,y,z) dx dy}{\iint_{-r_{in}}^{r_{in}} P(x,y,z) dx dy},$$

where $P(x, y, z)$ is a two-dimensional beam profile and r_{in} and r_{out} are inner and outer circle radii, respectively. For line-segmented quotients $Q_y(z)$ along the y -dimension, this can be rewritten as

$$Q_y(z) = \frac{\int_{-r_{out}}^{r_{out}} P(x,z) dx}{\int_{-r_{in}}^{r_{in}} P(x,z) dx}.$$

Without wishing to be bound by this theory, the overall defocused beam profile $P(x, z)$ can be regarded as a superposition of defocused image point profiles $p(x, z)$ along the image width $b(x, z)$. This relationship can be modelled as a convolution given by

$$P(x, z) = b(x, z) * p(x, z),$$

wherein $p(x, z)$ represents the Point-Spread-Function (PSF) of a lens in defocus, which in the field of paraxial optics is also known as Circle of Confusion (CoC). By inserting $P(x, z)$ into $Q_y(z)$ the above described quotient $Q_y(z)$ can be rewritten as

$$Q_y(z) = \frac{\int_{-r_{out}}^{r_{out}} b(x,z) * p(x,z) dx}{\int_{-r_{in}}^{r_{in}} b(x,z) * p(x,z) dx} = \frac{\int_{-r_{out}}^{r_{out}} b(x,z) dx \cdot \int_{-r_{out}}^{r_{out}} p(x,z) dx}{\int_{-r_{in}}^{r_{in}} b(x,z) dx \cdot \int_{-r_{in}}^{r_{in}} p(x,z) dx}.$$

The CoC radius may be r_c and r_o may be an image spot radius of the feature on the matrix of optical sensors, then $r_{out} = r_c + r_o \Rightarrow r_{out} \geq r_c$ and $r_{out} \geq r_o$, which yields to

$$Q_y(z) = \frac{\int_{-r_o}^{r_o} b(x,z)dx \cdot \int_{-r_c}^{r_c} p(x,z)dx}{\int_{-r_{in}}^{r_{in}} b(x,z)dx \cdot \int_{-r_{in}}^{r_{in}} p(x,z)dx}.$$

In case of $r_o \leq r_{in} < r_c$,

$$Q_y(z) = \frac{\int_{-r_o}^{r_o} b(x,z)dx \cdot \int_{-r_c}^{r_c} p(x,z)dx}{\int_{-r_o}^{r_o} b(x,z)dx \cdot \int_{-r_{in}}^{r_{in}} p(x,z)dx} = \frac{\int_{-r_c}^{r_c} p(x,z)dx}{\int_{-r_{in}}^{r_{in}} p(x,z)dx},$$

which indicates that the quotient is independent of the object size on condition that $r_o < r_c$.

The Object Size Independence (OSI) in DPR applies as long as the image width i remains below the Circle of Confusion (CoC) width denoted as c . In the one-dimensional case, this is represented by diameters $d_o < d_c$. Using paraxial optics, these diameters can be substituted, such that

$$\frac{i}{a} o_s < \frac{D_x}{i} |d - i|,$$

with a as the object distance, i as the image distance, o_s as the object size, D_x as the lens exit pupil diameter and d as the sensor position with respect to image-side principal plane. After re-arranging, this can be written as

$$o_s < \frac{a D_x}{i^2} |d - i|.$$

When focusing a single lens to infinity, this simplifies to

$$o_s < \frac{f}{F\#} \left| 1 - \frac{f}{a} \right|,$$

where f is the focal length and $F\#$ the F-number of the lens.

Furthermore, with a matrix of optical sensors a defocused beam profile may be subdivided into cross-sections along lines of a certain angle θ and with a distance ω from the origin of ordinates. Accordingly, the parameterization of a single line may be given by

$$\omega = x \cos(\theta) + y \sin(\theta).$$

The integration of the intensity along parallel lines can be mathematically described by an integral projection $\Re\{\cdot\}$ of the well-known Radon transform which reads

$$\Re_{(\omega,\theta)}\{f(x,y)\} = \iint_{-\infty}^{\infty} f(x,y) \delta(x \cos(\theta) + y \sin(\theta) - \omega) dx dy,$$

where δ denotes the Dirac delta function and $f(x,y)$ is the intensity of an enclosed defocused beam profile. The photon ratio R for a given angle θ and projection width ω is given by

$$R = \frac{\Re_{(\omega,\theta)}\{f'(x,y)\}}{\Re_{(\omega,\theta)}\{f(x,y)\}},$$

with $f'(x,y)$ as the inner region. The variation of θ may yield different ratios R for skewed object surfaces at a certain distance. It is sufficient to let θ vary in the following interval $\{\theta \in \mathbb{R}_+, \theta < \pi\}$.

In one embodiment, the light beam propagating from the object to the detector may illuminate the sensor element with at least one pattern comprising at least one feature point. As used herein, the term "feature point" refers to at least one at least partially extended feature of the pattern. The feature point may be selected from the group consisting of: at least one point, at

least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors. The central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

For example, the light beam propagating from the object to the detector may illuminate the optical sensors with at least one line pattern. The line pattern may be generated by the object, for example in response to an illumination by the at least one illumination source with an illumination pattern comprising the at least one line pattern. A1 may correspond to an area with a full line width of the line pattern on the optical sensors, in particular on the light sensitive area of the optical sensors. The line pattern on the optical sensors may be widened and/or displaced compared to the line pattern of the illumination pattern such that the line width on the optical sensors is increased. In particular, in case of a matrix of optical sensors, the line width of the line pattern on the optical sensors may change from one column to another column. A2 may be a central area of the line pattern on the optical sensors. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern may be segmented on the optical sensors. Each column of the matrix of optical sensors may comprise center information of intensity in the central area of the line pattern and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern.

For example, the light beam propagating from the object to the detector may illuminate the sensor element with at least one point pattern. The point pattern may be generated by the object, for example in response to an illumination by the at least one light source with an illumination pattern comprising the at least one point pattern. A1 may correspond to an area with a full radius of a point of the point pattern on the optical sensors. A2 may be a central area of the point in the point pattern on the optical sensors. The central area may be a constant value. The central area may have a radius compared to the full radius. For example, the central area may have a radius from 0.1 to 0.9 of the full radius, preferably from 0.4 to 0.6 of the full radius.

The light beam propagating from the object to the detector may illuminate the sensor element with a reflection pattern comprising both point patterns and line patterns. Other embodiments in addition or alternatively to line pattern and point pattern are feasible.

For example, the optical sensors may comprise a first optical sensor having a first light sensitive area and a second optical sensor having a second light sensitive area, wherein the first and the second light sensitive areas are arranged such that a condition

$$\frac{a}{c} \neq \frac{b}{d}$$

is satisfied, wherein “a” is a ratio of photons hitting both an inner region of a plane perpendicular to the optical axis intersecting the optical axis at a distance equal to half of a focal length of the transfer device and the first light sensitive area, “b” is a ratio of photons hitting both the inner region of the plane and the second light sensitive area, “c” is a ratio of photons hitting both an outer region of the plane and the first light-sensitive area, “d” is a ratio of the photons hitting both the outer region of the plane and the second light sensitive area. The first light sensitive area and the second light sensitive areas may be arranged such that the inner region may have an area with a geometrical center point on the optical axis and an extension such that half of the photons hit the plane within the inner region and the other half hit the plane outside the inner region. The first light sensitive area and the second light sensitive areas may be arranged such that the inner region may be designed as a circle with a center point on the optical axis and a radius r which is chosen such that half of the photons hit the plane within the circle and the other half hit the plane outside the circle.

As outlined above, the detector may comprise at least one illumination source. A distance perpendicular to an optical axis of the detector between the illumination source and the optical sensors may be small. The distance perpendicular to the optical axis of the detector between the illumination source and the optical sensors may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. The illumination source and the optical axis may be separated by a small baseline. As used herein, the term “baseline”, also denoted as basis line, refers to a distance, for example in a xy -plane, between the optical axis and the illumination source, in particular a distance between the optical axis and a z-component of the illumination light beam. The illumination source may be spaced apart from the optical axis by a minimum distance. The minimum distance from the optical axis may be defined by further detector elements such as size and position of the optical sensors and of the at least one optional transfer device, which will be described in detail below. The baseline may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. For example, the baseline may be 21 mm. Preferably, the illumination source may be arranged right next to the transfer device. For example, the transfer device may be flattened such that the illumination source can be positioned even closer to the optical axis. The illumination source may be arranged behind the transfer device.

At least one of the optical sensors may be adapted to generate at least one sensor signal dependent on a time-of-flight (TOF) the illumination light beam has traveled from the illumination source to the object and the reflection light beam has traveled from the object to the light sensitive area of the optical sensor. The evaluation device may be configured for determining at least one TOF-longitudinal coordinate z_{TOF} of the object by evaluating the TOF sensor signal. The optical sensor adapted to generate the TOF sensor signal may be designed as time-of-flight detector. The time-of-flight detector may be selected from the group consisting of: at least one pulsed time-of-flight detector; at least one phase modulated time-of-flight detector; at least one direct time-of-flight detector; at least one indirect time-of-flight detector. For example, the pulsed time-of-flight detector may be at least one range gated imager and/or at least one direct time-of-flight imager. For example the phase modulated time-of-flight detector may be at least one RF-

modulated light source with at least one phase detector. The optical sensor may be adapted to determine a time delay between emission of the illumination light beam by the illumination source and receipt of the reflection light beam.

- 5 For example, the optical sensor adapted to generate the TOF sensor signal may be designed as pulsed time-of-flight detector. The detector may comprise the at least one interruption device, such as at least one shutter element, adapted to generate a pulsed light beam. The optical sensor may be adapted to store the TOF sensor signal dependent on the receiving time of the reflection light beam in a plurality of time windows, in particular subsequent time windows. The
- 10 optical sensor may be adapted to store dependent on receiving time of the reflection light beam the generated TOF sensor signal in at least one first time window and/or in at least one second time window. The first and second time windows may be correlated with the opening and closure of the interruption device. Duration of first and second time windows may be pre-defined. For example, the TOF sensor signal may be stored in the first time window during opening of
- 15 the interruption device, whereas during closure of the interruption device the TOF sensor signal may be stored in the second time window. Other durations of time windows are thinkable. The first and the second time window may comprise information about background, signal height and signal shift.
- 20 For example, the optical sensor adapted to generate the TOF sensor signal may be designed as direct time-of-flight imager. The direct time-of-flight imager may comprise the at least one illumination source adapted to generate at least one single laser pulse. The single laser pulse may be reflected back from the object onto the optical sensor. The optical sensor may comprise at least one photodiode, for example at least one Avalanche Photo Diode (APD), such as at
- 25 least one Si APD, or such as at least one InGaAs APD, or at least one PIN photo detector array, or at least one Single-Photon Avalanche Photodiode (SPAD), adapted to image the reflection light beam. The direct time-of flight imager may be adapted to image at least one image comprising spatial and temporal data.
- 30 For example, the optical sensor adapted to generate the TOF sensor signal may be designed as phase modulated time-of-flight modulator. The phase modulated time-of-flight modulator may be adapted to measure a difference in phase, in particular a phase shift, by determining a correlated signal, for example by multiplying a received signal, i.e. of the reflection light beam, with the emitted signal, i.e. the illumination light beam. A DC component of the correlated signal may
- 35 comprise an information about the difference in phase. The evaluation device may be adapted to determine the second longitudinal coordinate of the object from the phase difference. For example, the illumination source and the optical sensor adapted to generate the TOF sensor signal may be designed as RF-modulated light source with at least one phase detector. The illumination source may comprise, for example, at least one LED and/or at least one laser. The
- 40 illumination source may comprise at least one modulation device adapted to modulate the light beam having a pre-defined phase shift. For example, the modulation device may comprise at least one radio frequency module. The radio frequency module may be adapted to modulate the

illumination beam with an RF carrier. The optical sensor may be adapted to determine a phase shift of the reflective light beam impinging on the optical sensor.

The optical sensor may be designed as and/or may comprise at least one time-of-flight pixel.

- 5 Preferably, the detector may comprise at least two optical sensors, wherein each optical sensor is designed as and/or comprises at least one TOF pixel. For example, the detector, in particular the optical sensor may comprise a quadrant diode adapted to generate the TOF sensor signal. For example, the detector, in particular the optical sensor, may comprise at least one pixelated TOF-imager.

10

The evaluation device may be configured for determining the at least one TOF longitudinal coordinate z_{TOF} of the object by evaluating the TOF sensor signal. As used herein, the term "TOF longitudinal coordinate" refers to a longitudinal coordinate derived from the TOF sensor signal.

- 15 As described above, the illumination light source may be adapted to periodically generate at least one light pulse. The detector may be adapted to generate the first longitudinal sensor signal for each period. The evaluation device may be adapted to determine in which pulse period the TOF sensor signal was generated using the second longitudinal coordinate. The detector may be adapted to uniquely assign to which period the ToF-signal refers to by using the combined sensor signal. Both, the TOF sensor signal and the combined sensor signal, may be non-monotonous functions of the longitudinal coordinate z_{real} . Thus, the longitudinal coordinate may not be uniquely determined from one of the TOF sensor signal or the combined sensor signal alone and a measurement range may not be restricted to a longitudinal range in which the signals are unique functions of z_{real} . The term "measurement range" generally refers to a range from the object to the detector in which determination of the longitudinal coordinate is possible.

- 25 The term "longitudinal range" generally refers to a range from the object to the detector in which unique determination of the longitudinal coordinate is possible. Below and/or above certain distances from the object to the detector a determination of the longitudinal coordinate may not be possible. For example, time-of-flight measurements are not possible below a certain distance from the object to the detector, possibly due to the minimum measurement time of the internal clock. Furthermore, in time-of-flight measurements the sensor signal may be unique within a longitudinal period, but the sensor signal may be the same in case integer multiples of the longitudinal period are added such that the determined longitudinal coordinate may be non-unique. Thus, the same TOF sensor signal will be obtained for a distance z_1 and a distance $z_1 + n \cdot z_{1p}$, where n is an integer denoting the longitudinal period and z_{1p} is the longitudinal period of the TOF sensor signal, wherein the distances z_1 and $z_1 + n \cdot z_{1p}$ are within the measurement range.
- 35 As used herein, the term "longitudinal period" refers to partitions of a period, in particular a distance range, in which the longitudinal coordinate can be unambiguously determined from the TOF sensor signal. Non-unique longitudinal coordinates may be denoted as relative longitudinal coordinates and the unique longitudinal coordinates may be denoted as absolute longitudinal coordinates.
- 40

If both the TOF sensor signal $F1$ and the combined sensor signals $F2$ are available, it may be possible to uniquely determine the longitudinal coordinate and to extend the longitudinal range,

as long as each signal pair (F1,F2) corresponds to a unique distance and vice versa. In particular, if a unique signal pair (F1,F2) exists for each longitudinal coordinate and vice versa, the evaluation device may be adapted to determine the unique combined longitudinal coordinate by

- (1) selecting at least one first selected signal such as the TOF sensor signal and/or the combined sensor signal and determining non-unique first longitudinal coordinates;
- (2) selecting a second selected signal such as the combined signal Q and/or the TOF sensor signal, which was not selected in step (1), and determining non-unique second longitudinal coordinates;
- (3) determining whether one of the non-unique first longitudinal coordinates and the non-unique second longitudinal coordinates match up to a predetermined tolerance threshold;
- (4) setting a combined unique longitudinal coordinate to be a matching longitudinal coordinate.

In step (1) and step (2), signals may be selected in the given order or may be performed in a different order. For example, in step (1) the TOF sensor signal may be selected and in step (2) the combined signal Q may be selected. In another example, in step (1) the combined sensor signal may be selected, and the non-unique first longitudinal sensor signal may be determined therefrom. In step (2), the TOF sensor signal may be selected.

Additionally or alternatively to step (4), the evaluation device may be adapted to output an error signal in case no matching coordinates are found and/or to output an error signal in case more than one matching coordinates are found. Additionally or alternatively, the signal pairs and their corresponding longitudinal coordinates may be stored in a look-up table. Additionally or alternatively, the signal pairs and their corresponding longitudinal coordinates may be approximated or described by an analytical function which is evaluated to find the longitudinal coordinate corresponding to a given signal pair.

The evaluation device may comprise at least two memory elements. As used herein, the term “memory element” refers to a device adapted to store information. The evaluation device may be adapted to receive and to store information provided by the optical sensors, for example the at least one first sensor signal. Such information may comprise raw sensor data and/or processed sensor data. For example, the memory element may be adapted to store information for further evaluation by the evaluation device. The memory element may be a volatile or non-volatile memory element.

As described above, the optical sensor may be designed as and/or may comprise at least one ToF pixel. The detector may comprise at least two switches. Each of the switches may be connected to the optical sensor adapted to generate the first sensor signal, for example by at least one connector. In particular, each of the switches may be connected to the ToF pixel. The switches are adapted to provide the TOF sensor signal to one of the memory elements. In particular, the switches may be adapted to let, dependent on receiving time of the reflection light beam, the generated TOF sensor signal pass through one of the switches. For example, the TOF sensor signal may pass one of the switches during opening of the interruption device, whereas during closure of the interruption device the TOF sensor signal may pass the other

switch. Each of the switches may be controlled by a control signal having a pulse length identical to a pulse length of a light pulse generated by the illumination source. The control signal of one of the switches may be delayed. For example, the delay may correspond to the pulse length of the light pulse. The evaluation device may be adapted to sample and/or store depending on the delay a first part, or fraction, of the TOF sensor signal through a first switch in a first memory element and the other, second part, or fraction, of the TOF sensor signal through a second switch in a second memory element. The evaluation device may be adapted to determine the first longitudinal coordinate by evaluating the first part and second part of the TOF sensor signal. The evaluation device may be adapted to determine the first longitudinal coordinate z_1 by

$$z_1 = \frac{1}{2} \cdot c \cdot t_0 \cdot \frac{S_{12}}{S_{11} + S_{12}} + z_0;$$

wherein c is the speed of light, t_0 is the pulse length of the illumination light beam, z_0 is a distance offset often determined by the resolution of the time measurement, and S_{11} and S_{12} are the first part and second part of the TOF sensor signal, respectively.

As outlined above, the detector may further comprise one or more additional elements such as one or more additional optical elements. Further, the detector may fully or partially be integrated into at least one housing.

In a first preferred embodiment of the present invention, the detector may comprise:

- at least one first optical sensor having a first light-sensitive area, wherein the first optical sensor may be configured to generate at least one first sensor signal in response to an illumination of the first light-sensitive area by a light beam propagating from the object to the detector;
- at least one second optical sensor having a second light-sensitive area, wherein the second optical sensor may be configured to generate at least one second sensor signal in response to an illumination of the second light-sensitive area by the light beam, wherein the first light-sensitive area may be smaller than the second light-sensitive area; and
- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating the first and second sensor signals.

In this first preferred embodiment the optical sensors may be arranged such that the light-sensitive areas of the optical sensors differ in their longitudinal coordinate and/or their surface areas.

As will further be outlined in detail below, each optical sensor, preferably, may be embodied such that precisely one light-sensitive area is present in the respective optical sensor, such as by providing precisely one light-sensitive area which may be illuminated, in response to which illumination precisely one uniform sensor signal is created for the whole optical sensor. Thus, preferably, each optical sensor is a single area optical sensor rather than a pixelated optical sensor like e.g. a sensor matrix. Other embodiments, however, are feasible. The use of the single area optical sensors, however, renders the setup of the detector specifically simple and effi-

cient. Thus, as an example, commercially available photo-sensors, such as commercially available silicon photodiodes, each having precisely one sensitive area, may be used in the setup, one with a small light-sensitive area and one with a larger light-sensitive area, as will be explained in further detail below.

5

The first and second light-sensitive areas specifically may be oriented towards the object.

The light beam propagating from the object to the detector specifically may fully illuminate the first light-sensitive area, such that the first light-sensitive area is fully located within the light beam, with a width of the light beam being larger than the light-sensitive area of the first optical sensor. Contrarily, preferably, the light beam propagating from the object to the detector specifically may create a light spot on the second light-sensitive area, which is smaller than the second light-sensitive area, such that the light spot is fully located within the second light-sensitive area. Within the light spot on the second light-sensitive area, a shadow created by the first optical sensor may be located. Thus, generally, the first optical sensor, having the smaller first light-sensitive area, may be located in front of the second optical sensor, as seen from the object, with the first light-sensitive area being fully located within the light beam and with the light beam generating a light spot on the second light-sensitive area being smaller than the second light-sensitive area, and with further a shadow created by the first optical sensor within the light spot. The situation may easily be adjusted by a person skilled in the art of optics by choosing one or more appropriate lenses or elements having a focusing or defocusing effect on the light beam, such as by using an appropriate transfer device as will be outlined in further detail below. As further used herein, a light spot generally refers to a visible or detectable round or non-round illumination of an article, an area or object by a light beam.

25

As outlined above, the first light-sensitive area is smaller than the second light-sensitive area. As used therein, the term "is smaller than" refers to the fact that the surface area of the first light-sensitive area is smaller than the surface area of the second light-sensitive area, such as by at least a factor of 0.9, e.g. at least a factor of 0.7 or even by at least a factor of 0.5. As an example, both the first light-sensitive area and the second light-sensitive area may have the shape of a square or of a rectangle, wherein side lengths of the square or rectangle of the first light-sensitive area are smaller than corresponding side lengths of the square or rectangle of the second light-sensitive area. Alternatively, as an example, both the first light-sensitive area and the second light-sensitive area may have the shape of a circle, wherein a diameter of the first light-sensitive area is smaller than a diameter of the second light-sensitive area. Again, alternatively, as an example, the first light-sensitive area may have a first equivalent diameter, and the second light-sensitive area may have a second equivalent diameter, wherein the first equivalent diameter is smaller than the second equivalent diameter.

40

The first light-sensitive area specifically may overlap with the second light-sensitive area in a direction of propagation of the light beam. The light beam may illuminate both the first light-sensitive area and, fully or partially, the second light-sensitive area. Thus, as an example, as seen from an object located on an optical axis of the detector, the first light-sensitive area may

be located in front of the second light-sensitive area, such that the first light-sensitive area, as seen from the object, is fully located within the second light-sensitive area. When the light beam from this object propagates towards the first and second light-sensitive areas, as outlined above, the light beam may fully illuminate the first light-sensitive area and may create a light spot on the second light-sensitive area, wherein a shadow created by the first optical sensor is located within the light spot. It shall be noted, however, that other embodiments are feasible.

Specifically, as will be outlined in further detail below, the evaluation device may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between first and second sensor signals. In particular, the evaluation device is configured to determine the at least one coordinate z of the object by using at least one known, determinable or predetermined relationship between the quotient signal derived from the first and second sensor signals and the longitudinal coordinate.

Thus, the evaluation device specifically may be configured for deriving the quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals. As an example, Q may simply be determined as

$$Q = s_1/s_2$$

or

$$Q = s_2/s_1,$$

with s_1 denoting the first sensor signal and s_2 denoting the second sensor signal. Additionally or alternatively, Q may be determined as

$$Q = a \cdot s_1 / b \cdot s_2$$

or

$$Q = b \cdot s_2 / a \cdot s_1,$$

with a and b being real numbers which, as an example, may be predetermined or determinable. Additionally or alternatively, Q may be determined as

$$Q = (a \cdot s_1 + b \cdot s_2) / (c \cdot s_1 + d \cdot s_2),$$

with a , b , c and d being real numbers which, as an example, may be predetermined or determinable. As a simple example for the latter, Q may be determined as

$$Q = s_1 / (s_1 + s_2).$$

Other quotient signals are feasible.

Typically, in the setup described above, Q is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, the quotient $Q=s_1/s_2$ is a monotonously decreasing function of the size of the light spot. Without wishing to be bound by this theory, it is believed that this is due to the fact that, in the preferred setup described above, both the first signal s_1 and the second signal s_2 decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, the first signal s_1 decreases more rapidly than the second signal s_2 , since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. The quotient of the first and second sensor signals, thus, continuously decreases with increasing diameter of the light beam or diameter of the light spot on the first and second light-sensitive areas. The quotient, further, is mainly independent from the total power of the light beam, since the total power of the light beam forms a factor both in the first sensor signal and in the second sensor signal. Consequently, the quotient Q may form a secondary signal which provides a unique and unambiguous relationship between the first and second sensor signals and the size or diameter of the light beam. Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship between the first and second sensor signals and the longitudinal coordinate may exist. For the latter, reference e.g. may be made to WO 2014/097181 A1. The predetermined relationship may be determined by analytical considerations, such as by assuming a linear combination of Gaussian light beams, by empirical measurements, such as measurements measuring the first and second sensor signals or a secondary signal derived thereof as a function of the longitudinal coordinate of the object, or both.

The evaluation device is configured for determining the longitudinal coordinate by evaluating the quotient signal Q . The evaluation device may be configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate. The predetermined relationship may be one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship. The evaluation device may comprise at least one data storage device for storing the predetermined relationship, such as a lookup list or a lookup table.

The quotient signal Q may be determined by using various means. As an example, a software means for deriving the quotient signal, a hardware means for deriving the quotient signal, or both, may be used and may be implemented in the evaluation device. Thus, the evaluation device, as an example, may comprise at least one divider, wherein the divider is configured for deriving the quotient signal. The divider may fully or partially be embodied as one or both of a software divider or a hardware divider.

The first and second optical sensors specifically may be arranged linearly in one and the same beam path of the detector. As used herein, the term “linearly” generally refers to that the sensors are arranged along one axis. Thus, as an example, the first and second optical sensors both may be located on an optical axis of the detector. Specifically, the first and second optical sensors may be arranged concentrically with respect to an optical axis of the detector.

The first optical sensor may be arranged in front of the second optical sensor. Thus, as an example, the first optical sensor may simply be placed on the surface of the second optical sensor. Additionally or alternatively, the first optical sensor may be spaced apart from the second optical sensor by no more than five times the square root of a surface area of the first light-sensitive area. Additionally or alternatively, the first optical sensor may be arranged in front of the second optical sensor and may be spaced apart from the second optical sensor by no more than 50 mm, preferably by no more than 15 mm.

As outlined above, the second light-sensitive area is larger than the first light-sensitive area. Thus, as an example, the second light-sensitive area may be larger by at least a factor of two, more preferably by at least a factor of three and most preferably by at least a factor of five and the first light-sensitive area.

The first light-sensitive area specifically may be a small light-sensitive area, such that, preferably, the light beam fully illuminates this light-sensitive area. Thus, as an example which may be applicable to typical optical configurations, the first light-sensitive area may have a surface area of 1 mm² to 150 mm², more preferably a surface area of 10 mm² to 100 mm².

The second light-sensitive area specifically may be a large area. Thus, preferably, within a measurement range of the detector, light spots generated by a light beam propagating from the object of the detector may fully be located within the second light-sensitive area, such that the light spot is fully located within the borders of the second light-sensitive area. As an example, which is applicable e.g. in typical optical setups, the second light-sensitive area may have a surface area of 160 mm² to 1000 mm², more preferably a surface area of 200 mm² to 600 mm².

Infrared optical sensors which may be used for the first optical sensor, for the second optical sensor or for both the first and second optical sensors may be commercially available infrared optical sensors, such as infrared optical sensors commercially available from Hamamatsu Photonics Deutschland GmbH, D-82211 Herrsching am Ammersee, Germany. Thus, as an example, the first optical sensor, the second optical sensor or both the first and the second optical sensor may comprise at least one optical sensor of an intrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge photodiode, an InGaAs photodiode, an extended InGaAs photodiode, an InAs photodiode, an InSb photodiode, a HgCdTe photodiode. Additionally or alternatively, the first optical sensor, the second optical sensor or both the first and the second optical sensor may comprise at least one optical sensor of an extrinsic photovoltaic type, more preferably at least one semiconductor pho-

todiode selected from the group consisting of: a Ge:Ga photodiode, a Ge:Hg photodiode, a Ge:Cu photodiode, a Ge:Zn photodiode, a Si:Ga photodiode, a Si:As photodiode. Additionally or alternatively, the first optical sensor, the second optical sensor or both the first and the second optical sensor may comprise at least one bolometer, preferably a bolometer selected from the group consisting of a VO bolometer and an amorphous Si bolometer.

The first and second optical sensors each, independently, may be opaque, transparent or semi-transparent. For the sake of simplicity, however, opaque sensors which are not transparent for the light beam, may be used, since these opaque sensors generally are widely commercially available.

The first and second optical sensors each specifically may be uniform sensors having a single light-sensitive area each. Thus, the first and second optical sensors specifically may be non-pixelated optical sensors.

As outlined above, by evaluating the first and second sensor signals, the detector may be enabled to determine the at least one longitudinal coordinate of the object, including the option of determining the longitudinal coordinate of the whole object or of one or more parts thereof. In addition, however, other coordinates of the object, including one or more transversal coordinates and/or rotational coordinates, may be determined by the detector, specifically by the evaluation device. Thus, as an example, one or more additional transversal sensors may be used for determining at least one transversal coordinate of the object. Various transversal sensors are generally known in the art, such as the transversal sensors disclosed in WO 2014/097181 A1 and/or other position-sensitive devices (PSDs), such as quadrant diodes, CCD or CMOS chips or the like. These devices may generally also be implemented into the detector according to the present invention. As an example, a part of the light beam may be split off within the detector, by at least one beam splitting element. The split-off portion, as an example, may be guided towards a transversal sensor, such as a CCD or CMOS chip or a camera sensor, and a transversal position of a light spot generated by the split-off portion on the transversal sensor may be determined, thereby determining at least one transversal coordinate of the object. Consequently, the detector according to the present invention may either be a one-dimensional detector, such as a simple distance measurement device, or may be embodied as a two-dimensional detector or even as a three-dimensional detector. Further, as outlined above or as outlined in further detail below, by scanning a scenery or an environment in a one-dimensional fashion, a three-dimensional image may also be created. Consequently, the detector according to the present invention specifically may be one of a one-dimensional detector, a two-dimensional detector or a three-dimensional detector. The evaluation device may further be configured to determine at least one transversal coordinate x , y of the object.

In a further embodiment, the detector may comprise:

- at least one first optical sensor having a first light-sensitive area, wherein the first optical sensor may be configured to generate at least one first sensor signal in response to an illumination of the first light-sensitive area by a light beam propagating from the object to the detector;

- at least one second optical sensor having a second light-sensitive area, wherein the second optical sensor may be configured to generate at least one second sensor signal in response to an illumination of the second light-sensitive area by the light beam, wherein the first light-sensitive area and the second light sensitive area may be arranged such that the light-sensitive areas differ in their longitudinal coordinate; and
- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating the first and second sensor signals.

With respect to definitions and embodiments reference can be made to the description of the first preferred embodiment. In particular, the first light-sensitive area may be smaller than the second light-sensitive area.

In a further preferred embodiment of the present invention, the detector may comprise:

- at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor may be configured to generate at least one sensor signal in response to an illumination of the light-sensitive area by at least one light beam propagating from the object to the detector;
- at least one evaluation device may be configured for evaluating the sensor signals, by
 - a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
 - b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and
 - d) determining at least one longitudinal coordinate z of the object by evaluating the combined signal.

In this further preferred embodiment the optical sensors may be arranged such that the light-sensitive areas of the optical sensors differ in spatial offset and/or surface areas.

As used herein, the term "sensor element" generally refers to a device or a combination of a plurality of devices configured for sensing at least one parameter. In the present case, the parameter specifically may be an optical parameter, and the sensor element specifically may be an optical sensor element. The sensor element may be formed as a unitary, single device or as a combination of several devices. As further used herein, the term "matrix" generally refers to an arrangement of a plurality of elements in a predetermined geometrical order. The matrix, as will be outlined in further detail below, specifically may be or may comprise a rectangular matrix having one or more rows and one or more columns. The rows and columns specifically may be arranged in a rectangular fashion. It shall be outlined, however, that other arrangements are feasible, such as nonrectangular arrangements. As an example, circular arrangements are also feasible, wherein the elements are arranged in concentric circles or ellipses about a center point. For example, the matrix may be a single row of pixels. Other arrangements are feasible.

The optical sensors of the matrix specifically may be equal in one or more of size, sensitivity and other optical, electrical and mechanical properties. The light-sensitive areas of all optical sensors of the matrix specifically may be located in a common plane, the common plane preferably facing the object, such that a light beam propagating from the object to the detector may generate a light spot on the common plane.

As explained in more detail in e.g. in WO 2012/110924 A1 or WO 2014/097181 A1, typically, a predetermined or determinable relationship exists between a size of a light spot, such as a diameter of the light spot, a beam waist or an equivalent diameter, and the longitudinal coordinate of the object from which the light beam propagates towards the detector. Without wishing to be bound by this theory, the light spot, may be characterized by two measurement variables: a measurement signal measured in a small measurement patch in the center or close to the center of the light spot, also referred to as the center signal, and an integral or sum signal integrated over the light spot, with or without the center signal. For a light beam having a certain total power which does not change when the beam is widened or focused, the sum signal should be independent from the spot size of the light spot, and, thus, should, at least when linear optical sensors within their respective measurement range are used, be independent from the distance between the object and the detector. The center signal, however, is dependent on the spot size. Thus, the center signal typically increases when the light beam is focused, and decreases when the light beam is defocused. By comparing the center signal and the sum signal, thus, an item of information on the size of the light spot generated by the light beam and, thus, on the longitudinal coordinate of the object may be generated. The comparing of the center signal and the sum signal, as an example, may be done by forming the quotient signal Q out of the center signal and the sum signal and by using a predetermined or determinable relationship between the longitudinal coordinate and the quotient signal for deriving the longitudinal coordinate.

The use of a matrix of optical sensors provides a plurality of advantages and benefits. Thus, the center of the light spot generated by the light beam on the sensor element, such as on the common plane of the light-sensitive areas of the optical sensors of the matrix of the sensor element, may vary with a transversal position of the object. By using a matrix of optical sensors, the detector according to the present invention may adapt to these changes in conditions and, thus, may determine the center of the light spot simply by comparing the sensor signals. Consequently, the detector according to the present invention may, by itself, choose the center signal and determine the sum signal and, from these two signals, derive a combined signal which contains information on the longitudinal coordinate of the object. By evaluating the combined signal, the longitudinal coordinate of the object may, thus, be determined. The use of the matrix of optical sensors, thus, provides a significant flexibility in terms of the position of the object, specifically in terms of a transversal position of the object.

The transversal position of the light spot on the matrix of optical sensors, such as the transversal position of the at least one optical sensor generating the sensor signal, may even be used as an additional item of information, from which at least one item of information on a transversal position of the object may be derived, as e.g. disclosed in WO 2014/198629 A1. Additionally or

alternatively, as will be outlined in further detail below, the detector according to the present invention may contain at least one additional transversal detector for, in addition to the at least one longitudinal coordinate, detecting at least one transversal coordinate of the object.

5 Consequently, in accordance with the present invention, the term “center signal” generally refers to the at least one sensor signal comprising essentially center information of the beam profile. As used herein, the term “highest sensor signal” refers to one or both of a local maximum or a maximum in a region of interest. For example, the center signal may be the signal of the at least one optical sensor having the highest sensor signal out of the plurality of sensor signals
10 generated by the optical sensors of the entire matrix or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable within an image generated by the optical sensors of the matrix. The center signal may arise from a single optical sensor or, as will be outlined in further detail below, from a group of optical sensors, wherein, in the latter case, as an example, the sensor signals of the group of optical sensors may be added up, integrated or averaged, in order to determine the center signal. The group of optical sensors from
15 which the center signal arises may be a group of neighboring optical sensors, such as optical sensors having less than a predetermined distance from the actual optical sensor having the highest sensor signal, or may be a group of optical sensors generating sensor signals being within a predetermined range from the highest sensor signal. The group of optical sensors from
20 which the center signal arises may be chosen as large as possible in order to allow maximum dynamic range. The evaluation device may be adapted to determine the center signal by integration of the plurality of sensor signals, for example the plurality of optical sensors around the optical sensor having the highest sensor signal. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the
25 trapezoid, in particular of a plateau of the trapezoid.

Similarly, the term “sum signal” generally refers to a signal comprising essentially edge information of the beam profile. For example, the sum signal may be derived by adding up the sensor signals, integrating over the sensor signals or averaging over the sensor signals of the
30 entire matrix or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable within an image generated by the optical sensors of the matrix. When adding up, integrating over or averaging over the sensor signals, the actual optical sensors from which the sensor signal is generated may be left out of the adding, integration or averaging or, alternatively, may be included into the adding, integration or averaging. The evaluation
35 device may be adapted to determine the sum signal by integrating signals of the entire matrix, or of the region of interest within the matrix. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the entire trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of edge and center signals may be replaced by equivalent evaluations making use of properties of
40 the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

Additionally or alternatively, the evaluation device may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized for example by replacing the area integrals in the quotient signal Q by a line integrals along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or cuts may result in an improved distance information.

Similarly, the term “combined signal”, as used herein, generally refers to a signal which is generated by combining the center signal and the sum signal. Specifically, the combination may include one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal. Additionally or alternatively, the combined signal may comprise an arbitrary signal or signal combination which contains at least one item of information on a comparison between the center signal and the sum signal.

The light beam propagating from the object to the detector specifically may fully illuminate the at least one optical sensor from which the center signal is generated, such that the at least one optical sensor from which the center signal arises is fully located within the light beam, with a width of the light beam being larger than the light-sensitive area of the at least one optical sensor from which the sensor signal arises. Contrarily, preferably, the light beam propagating from the object to the detector specifically may create a light spot on the entire matrix which is smaller than the matrix, such that the light spot is fully located within the matrix. This situation may easily be adjusted by a person skilled in the art of optics by choosing one or more appropriate lenses or elements having a focusing or defocusing effect on the light beam, such as by using an appropriate transfer device as will be outlined in further detail below. As further used herein, a “light spot” generally refers to a visible or detectable round or non-round illumination of an article, an area or object by a light beam.

Specifically, as will be outlined in further detail below, the evaluation device may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between the sensor signals. In particular, the evaluation device is configured to determine the at least one coordinate z of the by using at least one known, determinable or predetermined relationship between a quotient signal derived from the sensor signals and the longitudinal coordinate.

As outlined above, the center signal generally may be a single sensor signal, such as a sensor signal from the optical sensor in the center of the light spot, or may be a combination of a plurality of sensor signals, such as a combination of sensor signals arising from optical sensors in the center of the light spot, or a secondary sensor signal derived by processing a sensor signal derived by one or more of the aforementioned possibilities. The determination of the center signal

may be performed electronically, since a comparison of sensor signals is fairly simply implemented by conventional electronics, or may be performed fully or partially by software. Specifically, the center signal may be selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

As outlined above, raw sensor signals of the optical sensors may be used for evaluation or secondary sensor signals derived thereof. As used herein, the term "secondary sensor signal" generally refers to a signal, such as an electronic signal, more preferably an analogue and/or a digital signal, which is obtained by processing one or more raw signals, such as by filtering, averaging, demodulating or the like. Thus, image processing algorithms may be used for generating secondary sensor signals from the totality of sensor signals of the matrix or from a region of interest within the matrix. Specifically, the detector, such as the evaluation device, may be configured for transforming the sensor signals of the optical sensor, thereby generating secondary optical sensor signals, wherein the evaluation device is configured for performing steps a)-d) by using the secondary optical sensor signals. The transformation of the sensor signals specifically may comprise at least one transformation selected from the group consisting of: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency decomposition.; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be determined manually by a user or maybe determined automatically, such as by recognizing an object within an image generated by the optical sensors. As an example, a vehicle, a person or another type of predetermined object may be determined by automatic image recognition within an image, i.e. within the totality of sensor signals generated by

the optical sensors, and the region of interest may be chosen such that the object is located within the region of interest. In this case, the evaluation, such as the determination of the longitudinal coordinate, may be performed for the region of interest, only. Other implementations, however, are feasible.

5

As outlined above, the detection of the center of the light spot, i.e. the detection of the center signal and/or of the at least one optical sensor from which the center signal arises, may be performed fully or partially electronically or fully or partially by using one or more software algorithms. Specifically, the evaluation device may comprise at least one center detector for detecting the at least one highest sensor signal and/or for forming the center signal. The center detector specifically may fully or partially be embodied in software and/or may fully or partially be embodied in hardware. The center detector may fully or partially be integrated into the at least one sensor element and/or may fully or partially be embodied independently from the sensor element.

15

As outlined above, the sum signal may be derived from all sensor signals of the matrix, from the sensor signals within a region of interest or from one of these possibilities with the sensor signals arising from the optical sensors contributing to the center signal excluded. In every case, a reliable sum signal may be generated which may be compared with the center signal reliably, in order to determine the longitudinal coordinate. Generally, the sum signal may be selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; an integral of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal. Other options, however, exist.

20

25

35

40

The summing may be performed fully or partially in software and/or may be performed fully or partially in hardware. A summing is generally possible by purely electronic means which, typically, may easily be implemented into the detector. Thus, in the art of electronics, summing devices are generally known for summing two or more electrical signals, both analogue signals and digital signals. Thus, the evaluation device may comprise at least one summing device for forming the sum signal. The summing device may fully or partially be integrated into the sensor element or may fully or partially be embodied independently from the sensor element. The summing device may fully or partially be embodied in one or both of hardware or software.

As outlined above, the comparison between the center signal and the sum signal specifically may be performed by forming one or more quotient signals. Thus, generally, the combined signal may be a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of the center signal and a linear combination of the sum signal and the center signal or vice versa; forming a quotient of the sum signal and a linear combination of the sum signal and the center signal or vice versa; forming a quotient of an exponentiation of the center signal and an exponentiation of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal. Other options, however, exist. The evaluation device may be configured for forming the one or more quotient signals. The evaluation device may further be configured for determining the at least one longitudinal coordinate by evaluating the at least one quotient signal.

The evaluation device specifically may be configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate, in order to determine the at least one longitudinal coordinate. Thus, due to the reasons disclosed above and due to the dependency of the properties of the light spot on the longitudinal coordinate, the quotient signal Q typically is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, a simple quotient of the sensor signal s_{center} and the sum signal s_{sum} $Q = s_{\text{center}}/s_{\text{sum}}$ may be a monotonously decreasing function of the distance. Without wishing to be bound by this theory, it is believed that this is due to the fact that, in the preferred setup described above, both the center signal s_{center} and the sum signal s_{sum} decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, the center signal s_{center} decreases more rapidly than the sum signal s_{sum} , since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. The quotient of the center signal and the sum signal, thus, continuously decreases with increasing diameter of the light beam or diameter of the light spot on the light-sensitive areas of the optical sensors of the matrix. The quotient, further, is typically independent from the total power of the light beam, since the total power of the light beam forms a factor both in the center signal and in the sum sensor signal. Consequently, the quotient Q may form a secondary signal which provides a unique and unambiguous relationship between the center signal and the sum signal and the size or diameter of the light beam. Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship between the center signal and the sum signal on the one hand and the longitudinal coordinate on the other hand may exist. For the latter, reference e.g. may be made to WO 2014/097181 A1. The predetermined relationship may be determined by analytical considerations, such as by assuming a linear combination of Gaussian light beams, by empirical measurements, such as measurements measuring the combined sig-

nal and/or the center signal and the sum signal or secondary signals derived thereof as a function of the longitudinal coordinate of the object, or both.

Thus, generally, the evaluation device may be configured for determining the longitudinal coordinate by evaluating the quotient signal Q such as the combined signal. This determining may be a one-step process, such as by directly combining the center signal and the sum signal and deriving the longitudinal coordinate thereof, or may be a multiple step process, such as by firstly deriving the combined signal from the center signal and the sum signal and, secondly, by deriving the longitudinal coordinate from the combined signal. Both options, i.e. the option of steps c) and d) being separate and independent steps and the option of steps c) and d) being fully or partially combined, shall be comprised by the present invention.

As outlined above, the optical sensors specifically may be or may comprise photodetectors, preferably inorganic photodetectors, more preferably inorganic semiconductor photodetectors, most preferably silicon photodetectors. Specifically, the optical sensors may be sensitive in the infrared spectral range. All of the optical sensors of the matrix or at least a group of the optical sensors of the matrix specifically may be identical. Groups of identical optical sensors of the matrix specifically may be provided for different spectral ranges, or all optical sensors may be identical in terms of spectral sensitivity. Further, the optical sensors may be identical in size and/or with regard to their electronic or optoelectronic properties.

The matrix may be composed of independent optical sensors. Thus, a matrix of inorganic photodiodes may be composed. Alternatively, however, a commercially available matrix may be used, such as one or more of a CCD detector, such as a CCD detector chip, and/or a CMOS detector, such as a CMOS detector chip.

Thus, generally, the optical sensors of the detector may form a sensor array or may be part of a sensor array, such as the above-mentioned matrix. Thus, as an example, the detector may comprise an array of optical sensors, such as a rectangular array, having m rows and n columns, with m, n, independently, being positive integers. Preferably, more than one column and more than one row is given, i.e. $n > 1$, $m > 1$. Thus, as an example, n may be 2 to 16 or higher and m may be 2 to 16 or higher. Preferably, the ratio of the number of rows and the number of columns is close to 1. As an example, n and m may be selected such that $0.3 \leq m/n \leq 3$, such as by choosing $m/n = 1:1$, $4:3$, $16:9$ or similar. As an example, the array may be a square array, having an equal number of rows and columns, such as by choosing $m=2$, $n=2$ or $m=3$, $n=3$ or the like.

As further outlined above, the matrix specifically may be a rectangular matrix having at least one row, preferably a plurality of rows, and a plurality of columns. As an example, the rows and columns may be oriented essentially perpendicular, wherein, with respect to the term “essentially perpendicular”, reference may be made to the definition given above. Thus, as an example, tolerances of less than 20° , specifically less than 10° or even less than 5° , may be acceptable. In order to provide a wide range of view, the matrix specifically may have at least 10

rows, preferably at least 50 rows, more preferably at least 100 rows. Similarly, the matrix may have at least 10 columns, preferably at least 50 columns, more preferably at least 100 columns. The matrix may comprise at least 50 optical sensors, preferably at least 100 optical sensors, more preferably at least 500 optical sensors. The matrix may comprise a number of pixels in a multi-mega pixel range. Other embodiments, however, are feasible. Thus, as outlined above, in setups in which an axial rotational symmetry is to be expected, circular arrangements or concentric arrangements of the optical sensors of the matrix, which may also be referred to as pixels, may be preferred.

As further outlined above, preferably, the sensor element may be oriented essentially perpendicular to an optical axis of the detector. Again, with respect to the term “essentially perpendicular”, reference may be made to the definition and the tolerances given above. The optical axis may be a straight optical axis or may be bent or even split, such as by using one or more deflection elements and/or by using one or more beam splitters, wherein the essentially perpendicular orientation, in the latter cases, may refer to the local optical axis in the respective branch or beam path of the optical setup.

The detector may be adapted to determine at least one distance information of the object by using triangulation and/or structured light techniques. In known 3D sensing devices, such as devices using triangulation or structured light techniques, due to correspondence problems regular, constant or periodic pattern are not suitable since each measured point has to be assigned to one reference point of a reference pattern. The at least one light beam propagating from the object to the detector may be adapted to generate at least one reflection pattern on the matrix of optical sensors. The term “reflection pattern” refers to at least one image determined by the optical sensors in response to illumination of the light sensitive areas by the light beam propagating from the object to the detector which was generated in response to illumination by the illumination pattern. The reflection pattern may comprise at least one reflection feature depending on the corresponding illumination feature of the illumination pattern. The detector may be adapted to determine the longitudinal coordinate of an object point for at least one reflection feature of the reflection pattern from the quotient signal. Thus, the detector may be adapted to pre-classify the at least one reflection feature of the reflection pattern. This allows using illumination patterns comprising regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that hexagonal patterns may be preferred.

The evaluation device may be adapted to perform at least one image analysis and/or image processing in order to identify the reflection feature. The image analysis and/or image processing may use at least one feature detection algorithm. The image analysis and/or image processing may comprise one or more of the following: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor

signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency decomposition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be determined manually by a user or may be determined automatically, such as by recognizing an object within an image generated by the optical sensors.

The evaluation device may be adapted to determine at least one reference feature in at least one reference pattern corresponding to the at least one reflection feature. The term "reference pattern" refers to an image of comparison at a specific spatial position comprising at least one reference feature. As outlined above, the evaluation device may be adapted to perform an image analysis and to identify features of the reflection pattern. The evaluation device may be adapted to identify at least one reference feature in the reference pattern having an essentially identical longitudinal coordinate as the selected reflection feature. The term "essentially identical" refers to identical within 10%, preferably 5%, most preferably 1%. The reference feature corresponding to the reflection feature may be determined using epipolar geometry. For description of epipolar geometry reference is made, for example, to chapter 2 in X. Jiang, H. Bunke: „Dreidimensionales Computersehen“ Springer, Berlin Heidelberg, 1997. Epipolar geometry may assume that the reference pattern and the reflection pattern may be images of the object determined at different spatial positions and/or spatial orientations having a fixed distance. The distance may be a relative distance, also denoted as baseline. The evaluation device may be adapted to determine an epipolar line in the reference pattern. The relative position of the reference pattern and reflection pattern may be known. For example, the relative position of the reference pattern and the reflection pattern may be stored within at least one storage unit of the evaluation device. The evaluation device may be adapted to determine a straight line extending from the selected reflection feature to the real world feature from which it originates. Thus, the straight line may comprise possible object features corresponding to the selected reflection feature. The straight line and the baseline span an epipolar plane. As the reference pattern is determined at a different relative constellation from the reflection pattern, the corresponding possible object features may be imaged on a straight line, called epipolar line, in the reference pattern. The epipolar line may be the intersection of the epipolar plane and the reference pattern. Thus, a feature of the reference pattern corresponding to the selected feature of the reflection pattern lies on the epipolar line.

Depending on the distance to the object, the reference feature corresponding to the image position of the reflection feature may be displaced within the reference pattern compared to the image position in the reflection pattern. The reference pattern may comprise at least one displacement region in which the reference feature corresponding to the selected reflection feature may be imaged. The displacement region may comprise only one reference feature. The dis-

placement region may extend along the epipolar line. The evaluation device may be adapted to determine the reference feature along the epipolar line. The evaluation device may be adapted to determine the longitudinal coordinate z for the reflection feature and an error interval $\pm \varepsilon$ from the quotient signal Q to determine a displacement region along the epipolar line corresponding to $z \pm \varepsilon$. The evaluation device may be adapted to match the selected reflection feature with at least one reference feature within the displacement region. As used herein, the term “matching” refers to determining and/or evaluating the corresponding reference and reflection features. The evaluation device may be adapted to match the selected feature of the reflection pattern with the reference feature within the displacement region by using at least one evaluation algorithm considering the determined longitudinal coordinate z . The evaluation algorithm may be a linear scaling algorithm. Preferably, the detector may be adapted to pre-classify the selected reflection feature using the quotient signal Q such that an unambiguous assignment to one reference feature is possible. In particular, illumination features of the illumination pattern may be arranged such that corresponding reference features of the reference pattern may have a relative distance to each other as large as possible on the epipolar line. The illumination features of the illumination pattern may be arranged such that only few reference features are positioned on the epipolar line. For example, the illumination pattern may comprise at least one hexagonal pattern. Preferably, the illumination pattern may comprise at least one hexagonal pattern, wherein the pattern is rotated relative to the baseline. Preferably, the illumination pattern may comprise at least one displaced hexagonal pattern, wherein individual points of the hexagonal pattern are displaced by a random distance from the regular position, for example orthogonal to the epipolar line of the point. The displacement of the individual points may be smaller than half of the distance between two parallel epipolar lines, preferably smaller than one fourth of the distance between two parallel epipolar lines. The displacement of the individual points may be as such that two points are not displaced above each other.

The evaluation device may be adapted to determine a displacement of the reference feature and the reflection feature. The evaluation device may be adapted to determine the displacement of the matched reference feature and the selected reflection feature. As used herein, the term “displacement” refers to the difference between an image position in the reference image to an image position in the reflection image. The evaluation device may be adapted to determine a longitudinal information of the matched feature using a predetermined relationship between a longitudinal coordinate and the displacement. As used herein, the term “longitudinal information” refers to information relating to the longitudinal coordinate z_{triang} . For example, the longitudinal information may be a distance value. The evaluation device may be adapted to determine the pre-determined relationship by using triangulation methods. In case the position of the selected reflection feature in the reflection pattern and the position of the matched reference feature and/or the relative displacement of the selected reflection feature and the matched reference feature are known, the longitudinal coordinate of the corresponding object feature may be determined by triangulation. Thus, the evaluation device may be adapted to select, for example subsequent and/or column by column, a reflection feature and to determine for each potential position of the reference feature the corresponding distance value using triangulation. The displacement and the corresponding distance value may be stored in at least one storage

device of the evaluation device. The evaluation device may, as an example, comprise at least one data processing device, such as at least one processor, at least one DSP, at least one FPGA and/or at least one ASIC. Further, for storing the at least one predetermined or determinable relationship between the longitudinal coordinate z and the displacement, the at least one data storage device may be provided, such as for providing one or more look-up tables for storing the predetermined relationship.

The detector may comprise at least one FiP sensor adapted for generating the so called FiP effect as described in WO 2015/024871 or WO2016/120392. For example, at least one optical sensors of the matrix of optical sensors may be adapted to generate a so called FiP signal. For example, each of the optical sensors of the matrix may be adapted to generate the at least one FiP signal. For example, the matrix of optical sensors may be a pixelated FiP-sensor. Additionally or alternatively, the FiP signal may be determined, such as extracted and/or simulated, from the sensor signals of the matrix and the quotient as outlined above may be determined from the sensor signals.

As outlined above, by evaluating the center signal and the sum signal, the detector may be enabled to determine the at least one longitudinal coordinate of the object, including the option of determining the longitudinal coordinate of the whole object or of one or more parts thereof. In addition, however, other coordinates of the object, including one or more transversal coordinates and/or rotational coordinates, may be determined by the detector, specifically by the evaluation device. Thus, as an example, one or more transversal sensors may be used for determining at least one transversal coordinate of the object. As outlined above, the position of the at least one optical sensor from which the center signal arises may provide information on the at least one transversal coordinate of the object, wherein, as an example, a simple lens equation may be used for optical transformation and for deriving the transversal coordinate. Additionally or alternatively, one or more additional transversal sensors may be used and may be comprised by the detector. Various transversal sensors are generally known in the art, such as the transversal sensors disclosed in WO 2014/097181 A1 and/or other position-sensitive devices (PSDs), such as quadrant diodes, CCD or CMOS chips or the like. Additionally or alternatively, as an example, the detector according to the present invention may comprise one or more PSDs disclosed in R.A. Street (Ed.): *Technology and Applications of Amorphous Silicon*, Springer-Verlag Heidelberg, 2010, pp. 346-349. Other embodiments are feasible. These devices may generally also be implemented into the detector according to the present invention. As an example, a part of the light beam may be split off within the detector, by at least one beam splitting element. The split-off portion, as an example, may be guided towards a transversal sensor, such as a CCD or CMOS chip or a camera sensor, and a transversal position of a light spot generated by the split-off portion on the transversal sensor may be determined, thereby determining at least one transversal coordinate of the object. Consequently, the detector according to the present invention may either be a one-dimensional detector, such as a simple distance measurement device, or may be embodied as a two-dimensional detector or even as a three-dimensional detector. Further, as outlined above or as outlined in further detail below, by scanning a scenery or an environment in a one-dimensional fashion, a three-dimensional image

may also be created. Consequently, the detector according to the present invention specifically may be one of a one-dimensional detector, a two-dimensional detector or a three-dimensional detector. The evaluation device may further be configured to determine at least one transversal coordinate x , y of the object. The evaluation device may be adapted to combine the information of the longitudinal coordinate and the transversal coordinate and to determine a position of the object in space.

The detector may be configured for evaluating a single light beam or a plurality of light beams. In case a plurality of light beams propagates from the object to the detector, means for distinguishing the light beams may be provided. Thus, the light beams may have different spectral properties, and the detector may comprise one or more wavelength selective elements for distinguishing the different light beams. Each of the light beams may then be evaluated independently. The wavelength selective elements, as an example, may be or may comprise one or more filters, one or more prisms, one or more gratings, one or more dichroitic mirrors or arbitrary combinations thereof. Further, additionally or alternatively, for distinguishing two or more light beams, the light beams may be modulated in a specific fashion. Thus, as an example, the light beams may be frequency modulated, and the sensor signals may be demodulated in order to distinguish partially the sensor signals originating from the different light beams, in accordance with their demodulation frequencies. These techniques generally are known to the skilled person in the field of high-frequency electronics. Generally, the evaluation device may be configured for distinguishing different light beams having different modulations.

The illumination source may be adapted to generate and/or to project a cloud of points such that a plurality of illuminated regions is generated on the matrix of optical sensor, for example the CMOS detector. Additionally, disturbances may be present on the matrix of optical sensor such as disturbances due to speckles and/or extraneous light and/or multiple reflections. The evaluation device may be adapted to determine at least one region of interest, for example one or more pixels illuminated by the light beam which are used for determination of the longitudinal coordinate of the object. For example, the evaluation device may be adapted to perform a filtering method, for example, a blob-analysis and/or object recognition method.

Preferably, the illumination source may be a movable and/or mobile illumination source. For example, the illumination source may be moved during the measurement such as to illuminate the object from different positions and/or angles. However, embodiments are feasible in which the illumination source may be positioned in at least one fixed position, for example during a complete measurement time. The evaluation device may be adapted to illumination sources with unclear position such as due to high manufacturing tolerances and/or user interaction and/or user assembly or the like.

The illumination source may illuminate the object with a convergent and/or divergent and/or collimated light beam.

In a further preferred embodiment the detector may comprise:

- at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different spatial offsets, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by a light beam propagating from the object to the detector; and
- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by combining the at least two sensor signals.

10 In this further preferred embodiment the optical sensors may be arranged such that the light-sensitive areas of the optical sensors differ in their spatial offset and/or their surface areas

The light-sensitive areas of the optical sensors may overlap, as visible from the object, or may not overlap, i.e. may be placed next to each other without overlap. The light-sensitive areas may be spaced apart from each other or may directly be adjacent.

The detector may comprise more than two optical sensors. In any case, i.e. in the case of the detector comprising precisely two optical sensors and in the case of the detector comprising more than two optical sensors, the optical sensors may comprise at least one first optical sensor being spaced apart from the optical axis by a first spatial offset and at least one second optical sensor being spaced apart from the optical axis by a second spatial offset, wherein the first spatial offset and the second spatial offset differ. In case further optical sensors are provided, besides the first and second optical sensors, these additional optical sensors may also fulfill the condition or, alternatively, may be spaced apart from the optical axis by the first spatial offset, by the second spatial offset or by a different spatial offset. The first and second spatial offsets, as an example, may differ by at least a factor of 1.2, more preferably by at least a factor of 1.5, more preferably by at least a factor of two. The spatial offsets may also be zero or may assume negative values, as long as the above-mentioned conditions are fulfilled.

30 As outlined above, each light-sensitive area has a geometrical center. Each geometrical center of each light-sensitive area may be spaced apart from the optical axis of the detector, such as the optical axis of the beam path or the respective beam path in which the respective optical sensor is located.

35 As outlined above, the optical sensors specifically may be located in one and the same plane, which, preferably, is a plane perpendicular to the optical axis. Other configurations, however, are possible. Thus, two or more of the optical sensors may also be spaced apart in a direction parallel to the optical axis.

40 For example, the optical sensors may be partial diodes of a segmented diode, with a center of the segmented diode being off-centered from the optical axis of the detector. As used herein, the term "partial diode" may comprise several diodes that are connected in series or in parallel. This example is rather simple and cost-efficiently realizable. Thus, as an example, bi-cell diodes

or quadrant diodes are widely commercially available at low cost, and driving schemes for these bi-cell diodes or quadrant diodes are generally known. As used herein, the term "bi-cell diode" generally refers to a diode having two partial diodes in one packaging. Bi-cell and quadrant diodes may have two or four separate light sensitive areas, in particular two or four active areas.

5 As an example, the bi-cell diodes may each form independent diodes having the full functionality of a diode. As an example, each of the bi-cell diodes may have a square or rectangular shape, and the two diodes may be placed in one plane such that the two partial diodes, in total, form a 1 x 2 or 2 x 1 matrix having a rectangular shape. In the present invention, however, a new scheme for evaluating the sensor signals of the bi-cell diodes and quadrant diode is proposed, as will be outlined in further detail below. Generally, however, the optical sensors specifically may be partial diodes of a quadrant diode, with a center of the quadrant diode being off-centered from the optical axis of the detector. As used herein, the term "quadrant diode" generally refers to a diode having four partial diodes in one packaging. As an example, the four partial diodes may each form independent diodes having the full functionality of a diode. As an example, the four partial diodes may each have a square or rectangular shape, and the four partial diodes may be placed in one plane such that the four partial diodes, in total, form a 2 x 2 matrix having a rectangular or square shape. In a further example, the four partial diodes, in total, may form a 2 x 2 matrix having a circular or elliptical shape. The partial diodes, as an example, may be adjacent, with a minimum separation from one another. However, the separation between adjacent diodes may also be varied to improve the dynamic range of the quotient signal. As an example, the separation between two adjacent diodes may be increased by using an opaque mask. This may reduce the light on one of the diodes relative and/or absolute as compared to the adjacent diode which will may increase a quotient of the signal of the two diodes.

25 In case a quadrant diode is used, having a 2x2 matrix of partial diodes, the center of the quadrant diode specifically may be off-centered or offset from the optical axis. Thus, as an example, the center of the quadrant diodes, which may be an intersection of the geometrical centers of the optical sensors of the quadrant diode, may be off-centered from the optical axis by at least 0.2 mm, more preferably by at least 0.5 mm, more preferably by at least 1.0 mm or even 2.0 mm. Similarly, when using other types of optical sensors setups having a plurality of optical sensors, an overall center of the optical sensors may be offset from the optical axis by the same distance.

35 As outlined above, bi-cell and quadrant diodes may have two or four separate light sensitive areas, in particular two or four active areas. The light sensitive areas may be separated by a dividing line. The dividing line, for example, of two Si-diodes, can be arranged parallel to the baseline of the detector, in particular parallel to a spot movement on the optical sensors. However, other arrangements are feasible. For example, the quadrant diode may comprise two dividing lines. The dividing lines may be arranged orthogonal to each other. The orthogonal arrangement of the dividing lines allows adjusting of the quotient signal for near field and far field applications independently from each other. In addition to determining the quotient signal of sensor signals of two optical sensors of the quadrant diode, the evaluation device may be adapted to determine a second quotient using at least three or all four sensor signals of the

quadrant diode. The two quotients can be formed such that two distinct distance ranges are covered. The two quotient signals for the near field and far field may have an overlap region in which both quotient signals allow obtaining reasonable determination of the longitudinal distance z . For example, the quotient signal may be determined by dividing the sensor signals of two top quadrants, also called top segment, by the sensor signals of two bottom quadrants, also called bottom segment. Using the quotient signal of sensor signals determined by two sensor areas which have a dividing line parallel to the baseline of the detector may allow determining of the quotient without any distance dependent movement of the light spot. In particular, as an example, if the dividing line between the top and bottom segment is parallel to the baseline, the quotient signal determined from top segment divided by bottom segment may be used in the near field, wherein the light spot may illuminate only one of a left or right segment of the quadrant diode. In this case determining the quotient signal by dividing sensor signals of the left and right segments may not be possible. However, determining the quotient by dividing the sensor signals of top and bottom segments may provide a reasonable distance measurement. The quotient signal determined by dividing sensor signals of the left and right segments may be used for far field measurement, wherein the light spot illuminates both left and right segments. Furthermore, the evaluation device may be adapted to determine the quotient signal by dividing sensor signals of opposing segments or neighboring segments. The evaluation device may be adapted to combine the acquired sensor signals of the quadrants such that distance measurement is possible over a wide range with a large resolution.

Generally, the light-sensitive areas of the optical sensors may have an arbitrary surface area or size. Preferably, however, specifically in view of a simplified evaluation of the sensor signals, the light-sensitive areas of the optical sensors are substantially equal, such as within a tolerance of less than 10%, preferably less than 5% or even less than 1%. This, specifically, is the case in typical commercially available quadrant diodes.

The detector may comprise at least one quadrant diode comprising four quadrants. For example, an upper left quadrant of the quadrant diode may be denoted "ol", a lower left quadrant "ul", an upper right quadrant may be denoted "or" and a lower right quadrant may be denoted "ur".

The light spot may move from the left in a small distance range to the left in a far distance range. The detector may comprise at least one neutral density filter. The quadrants of the small distance range may be covered by the neutral density filter. In the small distance range the quotient ol/ul may be used to determine the longitudinal coordinate z . In the far distance range a quotient or/ur and/or a quotient from a combination of all quadrants may be used. The neutral density filter allows that objects in the small distance range are adapted to illuminate the optical sensors brighter by constant amplification without saturating the amplifier. At the same time it is possible to obtain in the far distance range more of the signal. Thus, the neutral density filter allows to enhance dynamic of the detector.

Specifically, as will be outlined in further detail below, the evaluation device may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between sensor signals and/or any secondary signal derived thereof and the longitudinal coordinate. Thus, the evaluation device may be config-

ured for determining at least one combined sensor signal out of the at least two sensor signals, i.e. of the at least one sensor signal of at least one first optical sensor and out of the at least one sensor signal of at least one second optical sensor.

5 The detector may comprise at least one FiP sensor adapted for generating the so called FiP effect as described in WO 2015/024871 or WO2016/120392. For example, the bi-cell or quadrant diode may be adapted to generate a so called FiP signal. As outlined e.g. in WO
2015/024871 or WO2016/120392, the FiP signal can be used to determine depth information
10 over a wide distance range. The FiP sensor may be adapted to exhibit a positive and/or a negative FiP effect. According to the FiP-effect, the longitudinal sensor signal, given the same total power, may exhibit at least one pronounced maximum for one or a plurality of focusings and/or
15 for one or a plurality of specific sizes of the light spot on the sensor region or within the sensor region. For purposes of comparison, an observation of a maximum of the longitudinal sensor signal in a condition in which the corresponding material is impinged by a light beam with the
20 smallest possible cross-section, such as when the material may be located at or near a focal point as affected by an optical lens, may be denominated as a "positive FiP-effect". The negative FiP effect describes an observation of a minimum of the longitudinal sensor signal under a condition in which the corresponding material is impinged by a light beam with the smallest
25 available beam cross-section, in particular, when the material may be located at or near a focal point as effected by an optical lens. The negative FiP effect may be used to tune small image effects at high distances. Image changes such as position, size, shape, sharpness, etc. may vanish at high distances while the negative FiP effect increases. Furthermore, no luminance dependence may be introduced since both cells are at the same longitudinal position and thus receive identical photon density.

25 As outlined above, the detector may comprise the at least one illumination source. A distance perpendicular to an optical axis of the detector between the illumination source and the bi-cell or quadrant diode may be small. The distance perpendicular to the optical axis of the detector between the illumination source and the bi-cell or quadrant diode may be less than 0,1 m, preferably
30 less than 0,05 m, more preferably less than 0,025 m. The illumination source and the optical axis may be separated by a small baseline. The illumination source may be spaced apart from the optical axis by a minimum distance. The minimum distance from the optical axis may be defined by further detector elements such as size and position of the bi-cell or quadrant diode and of the at least one optional transfer device. The baseline may be less than 0,1 m, preferably
35 less than 0,05 m, more preferably less than 0,025 m. For example, the baseline may be 21 mm. Preferably, the illumination source may be arranged right next to the transfer device. For example, the transfer device may be flattened such that the illumination source can be positioned even closer to the optical axis. The illumination source may be arranged behind the transfer device.

40 As generally used herein, the term "combine" generally may refer to an arbitrary operation in which two or more components such as signals are one or more of mathematically merged in order to form at least one merged combined signal and/or compared in order to form at least

one comparison signal or comparison result. As will be outlined in further detail below, the combined sensor signal or secondary signal may be or may comprise at least one quotient signal.

In case more than two sensor signals are provided, as an example, more than one quotient signal may be generated, such as by forming quotient signals of more than one pair of sensor signals.

Thus, as an example, in case more than two optical sensors are provided, the above-mentioned quotient formation may take place between two of the sensor signals generated by these optical sensors or may take place between more than two of the sensor signals. Thus, instead of using the first one of the sensor signals and the second one of the sensor signals in the formulae given above, combined sensor signals may be used for quotient formation.

The quotient signal Q generally is an example for an asymmetry parameter denoting an asymmetry or an asymmetric distribution of the light spot generated by the light beam on the light-sensitive areas. The quotient of the two or more optical sensors, such as the two or more photodiodes, may provide a combined signal which typically is monotonously dependent on the distance between the detector and the object from which the light beam travels towards the detector, as will be shown by experimental data below. In addition or as an alternative to the quotient signal, other types of combined functions implementing the sensor signals of two or more sensors in the setup of the present invention may be used, which also may show a dependency on the distance between the object and the detector. The asymmetry or the asymmetry parameter of the light spot, as an example, may be an indication of the width of a light beam. If this asymmetry parameter depends on the distance only, the measurement can be used to determine the distance.

In typical setups, commercially available quadrant diodes such as quadrant photodiodes are used for positioning, i.e. for adjusting and/or measuring a transversal coordinate of a light spot in the plane of the quadrant photodiode. Thus, as an example, laser beam positioning by using quadrant photodiodes is well known. According to a typical prejudice, however, quadrant photodiodes are used for xy-positioning, only. According to this assumption, quadrant photodiodes are not suitable for measuring distances. The above-mentioned findings, however, using an off-centered quadrant photodiode with regard to an optical axis of the detector, show otherwise, as will be shown in further measurements below. Thus, as indicated above, in quadrant photodiodes, the asymmetry of the spot can be measured by shifting the quadrant diode slightly off-axis, such as by the above-mentioned offset. Thereby, a monotonously z-dependent function may be generated, such as by forming the quotient signal Q of two or more of the sensor signals of two or more partial photodiodes, i.e. quadrants, of the quadrant photodiode. Therein, in principle, only two photodiodes are necessary for the measurement. The other two diodes may be used for noise cancellation or to obtain a more precise measurement.

In addition or as an alternative to using a quadrant diode or quadrant photodiode, other types of optical sensors may be used. Thus, as will be shown in further detail below, staggered optical sensors may be used.

- 5 The use of quadrant diodes provides a large number of advantages over known optical detectors. Thus, quadrant diodes are used in a large number of applications in combination with LEDs or active targets and are widely commercially available at very low price, with various optical properties such as spectral sensitivities and in various sizes. No specific manufacturing process has to be established, since commercially available products may be implemented into
10 the detector according to the present invention.

The detector according to the present invention specifically may be used in multilayer optical storage discs, such as disclosed by international patent application number PCT/IB2015/052233, filed on March 26, 2015. Measurements performed by using the detector
15 according to the present invention specifically may be used in order to optimize the focus position in optical storage discs.

As will be outlined in further detail below, the distance measurement by using the detector according to the present invention may be enhanced by implementing one or more additional distance measurement means into the detector and/or by combining the detector with other types
20 of distance measurement means. Thus, as an example, the detector may comprise or may be combined with at least one triangulation distance measurement device. Thus, the distance measurement can be enhanced by making use of a combination of the measurement principle discussed above and a triangulation type distance measurement. Further, means for measuring
25 one or more other coordinates, such as x- and/or y-coordinates, may be provided.

In case a quadrant diode is used, the quadrant diode may also be used for additional purposes. Thus, the quadrant diode may also be used for conventional x-y-measurements of a light spot, as generally known in the art of optoelectronics and laser physics. Thus, as an example, the
30 lens or detector position can be adjusted using the conventional xy-position information of the quadrant diode to optimize the position of the spot for the distance measurement. As a practical example, the light spot, initially, may be located right in the center of the quadrant diode, which typically does not allow for the above-mentioned distance measurement using the quotient function Q. Thus, firstly, conventional quadrant photodiode techniques may be used for off-centering
35 a position of the light spot on the quadrant photodiode, such that, e.g., the spot position on the quadrant diode is optimal for the measurement. Thus, as an example, the different off-centering of the optical sensors of the detector may simply be a starting point for movement of the optical sensors relative to the optical axis such that the light spot is off-centered with respect to the optical axis and with respect to a geometrical center of the array of the optical sensors.

40

Thus, generally, the optical sensors of the detector may form a sensor array or may be part of a sensor array, such as the above-mentioned quadrant diode. The case $m=2$, $n=2$ is the case of

the quadrant diode or quadrant optical sensor, which, for practical reasons, is one of the preferred cases, since quadrant photodiodes are widely available.

As a starting point, a geometrical center of the optical sensors within the array may be off-centered from the optical axis, such as by the above-mentioned offset. The sensor array specifically may be movable relative to the optical axis, for example along a gradient, preferably automatically, such as by moving the sensor array, e.g. in a plane perpendicular to the optical axis, and/or by moving the optical axis itself, e.g. shifting the optical axis in a parallel shift and/or tilting the optical axis. Thus, the sensor array may be shifted in order to adjust a position of a light spot generated by the light beam in the plane of the sensor array. Additionally or alternatively, the optical axis may be shifted and/or tilted by using appropriate elements, such as by using one or more deflection elements and/or one or more lenses. The movement, as an example, may take place by using one or more appropriate actuators, such as one or more piezo actuators and/or one or more electromagnetic actuators and/or one or more pneumatic or mechanical actuators, which, e.g., move and/or shift the array and/or move and/or shift and/or tilt one or more optical elements in the beam path in order to move the optical axis, such as parallel shifting the optical axis and/or tilting the optical axis. The evaluation device specifically may be adjusted to control a relative position of the sensor array to the optical axis, e.g. in the plane perpendicular to the optical axis. An adjustment procedure may take place in that the evaluation device is configured for, firstly, determining the at least one transversal position of a light spot generated by the light beam on the sensor array by using the sensor signals and for, secondly, moving the array relative to the optical axis, such as by moving the array and/or the optical axis, e.g. by moving the array in the plane to the optical axis until the light spot is off-centered and/or by tilting a lens until the light spot is off-centered. As used therein, a transversal position may be a position in a plane perpendicular to the optical axis, which may also be referred to as the x-y-plane. For the measurement of the transversal coordinate, as an example, the sensor signals of the optical sensors may be compared. As an example, in case the sensor signals are found to be equal and, thus, in case it is determined that the light spot is located symmetrically with respect to the optical sensors, such as in the center of the quadrant diodes, a shifting of the array and/or a tilting of a lens may take place, in order to off-center the light spot in the array. Thus, as outlined above, the off-centering of the array from the optical axis, such as by off-centering the center of the quadrant photodiode from the optical axis, may simply be a starting point in order to avoid the situation which is typical, in which the light spot is located on the optical axis and, thus, is centered. By off-centering the array relative to the optical axis, thus, the light spot should be off-centered. In case this is found not to be true, such that the light spot, incidentally, is located in the center of the array and equally illuminates all optical sensors, the above-mentioned shifting of the array relative to the optical axis may take place, preferably automatically, in order to off-center the light spot on the array. Thereby, a reliable distance measurement may take place.

Further, in a scanning system with a movable light source, the position of the light spot on the quadrant diode may not be fixed. This is still possible, but may necessitate that different calibrations are used, dependent on the xy-position of the spot in the diode.

Further, the use of the above-mentioned quotient signal Q is a very reliable method for distance measurements. Typically, Q is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, the quotient $Q=s_1/s_2$ is a monotonously decreasing function of the size of the light spot. Without wishing to be bound by this theory, it is believed that this is due to the fact that, in the preferred setup described above, the sensor signals, such as the above-mentioned first sensor signal s_1 and the above-mentioned second sensor signal s_2 , decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, due to the off-centering, the one of the sensor signals decreases more rapidly than the other, since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. By spreading the light spot, however, the portion of the light illuminating the one or more optical sensors outside the center of the light spot increases, as compared to a situation of a very small light spot. Thus, the quotient of the sensor signals continuously changes, i.e. increases or decreases, with increasing diameter of the light beam or diameter of the light spot. The quotient, further, may further be rendered mainly independent from the total power of the light beam, since the total power of the light beam forms a factor in all sensor signals. Consequently, the quotient Q may form a secondary signal which provides a unique and unambiguous relationship between the sensor signals and the size or diameter of the light beam.

As outlined above, specifically, quadrant photodiodes may be used. As an example, commercially available quadrant photodiodes may be integrated in order to provide four optical sensors, such as one or more quadrant photodiodes available from Hamamatsu Photonics Deutschland GmbH, D-82211 Herrsching am Ammersee, Germany, such as quadrant Si PIN photodiodes of the type S4349, which are sensitive in the UV spectral range to the near IR spectral range. In case an array of optical sensors is used, the array may be a naked chip or may be an encapsulated array, such as encapsulated in a TO-5 metal package. Additionally or alternatively, a surface mounted device may be used, such as TT Electronics OPR5911 available from TT Electronics plc, Fourth Floor, St Andrews House, West Street Woking Surrey, GU21 6EB, England. It shall be noted that other optical sensors may also be used.

Further, it shall be noted that, besides the option of using precisely one quadrant photodiode, two or more quadrant photodiodes may also be used. Thus, as an example, a first quadrant photodiode may be used for the distance measurement, as described above, providing the two or more optical sensors. Another quadrant photodiode may be used, e.g. in a second partial beam path split off from the beam path of the first quadrant photodiode, for a transversal position measurement, such as for using at least one transversal coordinate x and/or y . The second quadrant photodiode, as an example, may be located on-axis with respect to the optical axis.

Further, it shall be noted that, besides the option of using one or more quadrant photodiodes, one or more quadrant photodiodes or further photodiode arrays may also be replaced or mim-

icked by separated photodiodes that are arranged or assembled close to each other, preferably in a symmetric shape such as a rectangular matrix, such as a 2 x 2 matrix. However further arrangements are feasible. In such an arrangement or assembly, the photodiodes may be arranged or assembled in a housing or mount, such as all photodiodes in a single housing or mount or groups of photodiodes in one housing or mount, or each of the photodiodes in a separate housing or mount. Further, the photodiodes may also be assembled directly on a circuit board. In such arrangements or assemblies, photodiodes may be arranged as such that the separation between the active area of the photodiodes, has a distinct value less than one centimeter, preferably less than one millimeter, more preferably as small as possible. Further, to avoid optical reflexes, distortions, or the like that may deteriorate the measurement, the space between the active areas may be either empty or filled with a material, preferably with a light absorbing material such as a black polymer, such as black silicon, black polyoxymethylene, or the like, more preferably optically absorbing and electrically insulating material, such as black ceramics or insulating black polymers such as black silicon, or the like. Further, the distinct value of the photodiode separation may also be realized by adding a distinct building block between the photodiodes such as a plastic separator. Further embodiments are feasible. The replacement of quadrant photodiodes by single diodes arranged in a similar setup such as in a 2 x 2 rectangular matrix with minimal distance between the active areas may further minimize the costs for the optical detector. Further, two or more diodes from a quadrant diode may be connected in parallel or in series to form a single light sensitive area.

The optical sensors each specifically may be uniform sensors having a single light-sensitive area each. Thus, the optical sensors specifically may be non-pixelated optical sensors.

In a further preferred embodiment the detector may comprise

- at least one first optical sensor having a first light-sensitive area, wherein the first optical sensor is configured to generate at least one first sensor signal in response to an illumination of the first light-sensitive area by a light beam propagating from the object to the detector;
- at least one second optical sensor having:
 - o at least one fluorescent waveguiding sheet forming a second light-sensitive area, wherein the fluorescent waveguiding sheet is oriented towards the object such that at least one light beam propagating from the object towards the detector generates at least one light spot in the second light-sensitive area, wherein the fluorescent waveguiding sheet contains at least one fluorescent material, wherein the fluorescent material is adapted to generate fluorescence light in response to the illumination by the light beam; and
 - o at least one photosensitive element located at at least one edge of the fluorescent waveguiding sheet, capable of detecting fluorescence light guided from the light spot towards the photosensitive element by the fluorescent waveguiding sheet and capable of generating at least one second sensor signal in response to the illumination of the second light-sensitive area by the light beam, wherein the first light-sensitive area is smaller than the second light-sensitive area; and

- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating the first and second sensor signals.

In this further preferred embodiment the optical sensors may be arranged such that the light-sensitive areas of the optical sensors differ in their spatial offset and/or their surface areas. The first and second light-sensitive areas specifically may be oriented towards the object

The light beam propagating from the object to the detector specifically may fully illuminate the first light-sensitive area, such that the first light-sensitive area is fully located within the light beam, with a width of the light beam being larger than the light-sensitive area of the first optical sensor. Contrarily, preferably, the light beam propagating from the object to the detector specifically may create a light spot on the second light-sensitive area, which is smaller than the second light-sensitive area, such that the light spot is fully located within the second light-sensitive area. Within the light spot on the second light-sensitive area, a shadow created by the first optical sensor may be located. Thus, generally, the first optical sensor, having the smaller first light-sensitive area, may be located in front of the second optical sensor, as seen from the object, with the first light-sensitive area being fully located within the light beam and with the light beam generating a light spot on the second light-sensitive area being smaller than the second light-sensitive area, and with further a shadow created by the first optical sensor within the light spot. The situation may easily be adjusted by a person skilled in the art of optics by choosing one or more appropriate lenses or elements having a focusing or defocusing effect on the light beam, such as by using an appropriate transfer device as will be outlined in further detail below. As further used herein, a light spot generally refers to a visible or detectable round or non-round illumination of an article, an area or object by a light beam.

The first and second optical sensors may be sensitive in one or more of the ultraviolet, the visible or the infrared spectral range. The first and second optical sensors may be sensitive in one and the same spectral range or may have differing spectral sensitivities.

As further used herein, a fluorescent waveguiding sheet generally refers to an element with both waveguiding properties and fluorescent properties. Therein, waveguiding generally refers to the property or a plurality of an element to guide the light in one or more of the ultraviolet, visible or the infrared spectral range by internal reflection, specifically by internal total reflection. The term "fluorescence" generally refers to the property of an element or a material to emit secondary light, also referred to as fluorescence light, in one or more of the ultraviolet, visible or infrared spectral range, in response to excitation by electromagnetic radiation, also referred to as primary radiation or excitation radiation, such as primary light or excitation light. In most cases, the emitted light, fluorescence light or secondary light has a longer wavelength and a lower energy than the primary radiation. The primary radiation typically induces the presence of excited states within the fluorescent material, such as so-called excitons. Typically, excited state decay times for photon emissions with energies from the UV to near infrared are within the range of 0.5 to 20 nanoseconds. Other examples, however, are feasible within the present invention. Similarly, as used herein, the term "fluorescent material" generally refers to a material having fluorescence

properties. The term “fluorescence light” generally refers to the secondary light generated during the above-mentioned fluorescence process.

For potential embodiments of the fluorescent waveguiding sheet, generally, reference may be made to the so-called “Q-Foil Technology”, as disclosed e.g. in the above-mentioned article by P. Bartu, R. Koeppel, N. Arnold, A. Neuling, L. Fallon, and S. Bauer, Conformable large-area position-sensitive photodetectors based on luminescence collecting silicone waveguides, J. Appl. Phys. 107, 123101 (2010). Fluorescent waveguiding sheets and/or second optical sensors as disclosed therein may also be used in the context of the present invention, within the second optical sensor.

The fluorescent waveguiding sheet, as will be outlined in further detail below, specifically may be an element or may comprise an element which has a sheet-like shape or which is a sheet. As used herein, a “sheet” generally refers to an element which has a lateral extension, such as a diameter or an equivalent diameter, which significantly exceeds a thickness of the element, such as by at least a factor of 5, more preferably by at least a factor of 10 or even more preferably by at least a factor of 20, a factor of 50 or even a factor of 100. The sheet specifically may be flexible, deformable or rigid.

As will be outlined in further detail below, the fluorescent waveguiding sheet specifically may be or may comprise a transparent material, specifically a transparent sheet. The transparency may be a transparency of at least 50 to 70% in the visible spectral range or in a part thereof, such as in a range of 500 nm to 700 nm. Other embodiments are feasible.

As further used herein, the term “sensitive area” generally refers to a two-dimensional or three-dimensional region of an element, specifically of the fluorescent waveguiding sheet or the optical sensor, which is sensitive to external influences and, e.g., produces at least one reaction in response to an external stimulus. In this case, specifically, the sensitive area may be sensitive to an optical excitation. The sensitive area specifically may be a part of a surface or the volume of the fluorescent waveguiding sheet, such as the whole surface of the fluorescent waveguiding sheet or a part thereof.

As further used herein, the term “fluorescent waveguiding sheet is oriented towards the object” generally refers to the situation that the surface of the fluorescent waveguiding sheet or a part of this surface, specifically the sensitive area, is fully or partially visible from the object. Specifically, at least one interconnecting line between at least one point of the object and at least one point of the sensitive area may form an angle with a surface element of the sensitive area or of the fluorescent waveguiding sheet which is different from 0°, such as an angle in the range of 20°-90°. Other embodiments, however, are feasible.

Most preferably, however, the at least one fluorescent waveguiding sheet, the sensitive area or a part thereof is oriented essentially perpendicular to an optical axis of the optical sensor and/or of the detector.

As further used herein, the term “edge” of the fluorescent waveguiding sheet generally refers to a boundary of the at least one fluorescent waveguiding sheet, such as a side boundary or side edge or a front or back face of the fluorescent waveguiding sheet. Thus, as the skilled person will recognize, the term “edge” of the fluorescent waveguiding sheet may generally refer to an interface or boundary between the fluorescent waveguiding sheet and a surrounding atmosphere, such as air. Specifically, the edge may be a border of a second light-sensitive area formed by the fluorescent waveguiding sheet. The term “located at” generally refers to the fact that the photosensitive elements are either located directly on the edge or in close proximity to the edge. As an example, at least 50% of the light emerging from the edge into the direction of the photosensitive element may be collected by the respective photosensitive element, without being lost by scattering, beam widening or other losses. As an example, the photosensitive element may be located at a position spaced apart from the edge of no more than 10 mm, more preferably of no more than 5 mm. It shall be noted, however, that other embodiments are feasible for connecting the fluorescence light. Most preferably, all photosensitive elements are located relative to their respective edges of the fluorescent waveguiding sheet in the same way, in order to provide similar measurement conditions for all photosensitive elements.

The at least one photosensitive element located at the at least one edge of the fluorescent waveguiding sheet may, as an example, be fully or partially located in the same plane as the fluorescent waveguiding sheet and/or may fully or partially be located in a different plane. In the latter case, as will be outlined in further detail below, as an example, an optical coupling between the edge of the fluorescent waveguiding sheet and the at least one photosensitive element may take place, by using at least one optical coupling element. Further, in case a plurality of photosensitive elements is provided in the second optical sensor, at least one of the photosensitive elements may be located in the same plane as the fluorescent waveguiding sheet and at least one of the photosensitive elements may be located outside the plane of the fluorescent waveguiding sheet. Further, a direction of view of the at least one photosensitive element may be parallel to the plane of the fluorescent waveguiding sheet or may be directed otherwise, such as perpendicular to the plane. Therein, when talking about a “plane” of the fluorescent waveguiding sheet, this term does not necessarily imply that the fluorescent waveguiding sheet is fully planar. Thus, as an example, the fluorescent waveguiding sheet may also be curved or bent, and the plane of the fluorescent waveguiding sheet at the location of the at least one photosensitive element may be a local tangential plane.

The term “edge” of the fluorescent waveguiding sheet, as used herein, may refer to a straight line or straight border area of the fluorescent waveguiding sheet, in the following also referred to as a “straight edge”, or may also refer to a non-straight line or non-straight border area of the fluorescent waveguiding sheet, such as a corner of the fluorescent waveguiding sheet. Thus, the at least one photosensitive element or, in case a plurality of photosensitive elements is provided, at least one of the photosensitive elements, may also be located at at least one corner of the fluorescent waveguiding sheet, such as at at least one corner of the second light-sensitive area formed by the fluorescent waveguiding sheet. Thus, specifically, the edge may comprise a

rim or a portion of a rim of the fluorescent waveguiding sheet, such as a corner and/or a straight rim portion. Additionally or alternatively, however, the edge may also comprise a flat surface of the fluorescent waveguiding sheet, such as a front side or back side.

- 5 As already outlined above, in order to improve feeding fluorescence light guided from the light spot towards the at least one photosensitive element into the at least one respective photosensitive element, at least one optical coupling may take place, by using at least one optical coupling element in between the fluorescent waveguiding sheet and the respective photosensitive element. Thus, the at least one photosensitive element, or, in case a plurality of photosensitive
- 10 elements is provided, at least one of the photosensitive elements may be optically coupled to the fluorescent waveguiding sheet by at least one optical coupling element configured for at least partially coupling the fluorescence light guided by the fluorescent waveguiding sheet out of the fluorescent waveguiding sheet and, preferably, at least partially into the photosensitive element. As used herein, the term "optical coupling element" generally refers to an arbitrary element
- 15 which is configured for one or more of disturbing, diminishing or interrupting an internal total reflection within the fluorescent waveguiding sheet which takes place during waveguiding within the fluorescent waveguiding sheet. Thus, as an example, the optical coupling element may be an arbitrary transparent element having an index of refraction in between an index of refraction of the fluorescent waveguiding sheet and the photosensitive element and/or the ambient atmosphere, such as air. Thus, as an example, in case an index of refraction of the fluorescent waveguiding sheet is denoted by n_1 , and an index of refraction of the photosensitive element is denoted by n_2 , an index of refraction n_3 of the optical coupling element may be
- 20 $n_1 < n_3 < n_2$ or $n_1 > n_3 > n_2$.
- 25 The optical coupling element may be in direct contact with the fluorescent waveguiding sheet, such as with at least one surface, such as a surface facing the object and/or a surface facing away from the object, of the fluorescent waveguiding sheet. Further, the optical coupling element may also be in direct contact with the at least one photosensitive element. Further, for each photosensitive element, an independent optical coupling element may be provided, or alternatively, a plurality of photosensitive elements may share a common optical coupling element, or, alternatively, a plurality of optical coupling elements may be coupled to one photosensitive element.
- 30

- Various ways of optical coupling are generally known to the skilled person and may also be
- 35 used for coupling fluorescence light from the fluorescent waveguiding sheet into the photosensitive element. Thus, as an example, the at least one optical coupling element may comprise at least one element selected from the group consisting of: a portion of transparent adhesive attaching the photosensitive element to the fluorescent waveguiding sheet; an etched portion within the fluorescent waveguiding sheet, such as within a surface of the fluorescent waveguiding sheet, such as a surface facing the object and/or facing away from the object; a scratch in the fluorescent waveguiding sheet, such as a scratch in the surface of the fluorescent waveguiding sheet, such as a surface facing the object and/or facing away from the object; a prism. Additionally or alternatively, other optical coupling elements are generally known and may also
- 40

be used in the present invention. In a most simple case, the at least one photosensitive element may simply be adhered or glued to a surface of the fluorescent waveguiding sheet, such as by at least one transparent glue or adhesive, e.g. a transparent epoxy. Other ways of optical coupling are feasible.

5

The first optical sensor and the second optical sensor specifically may have an essentially identical electrical capacitance. When referring to a capacitance of an optical sensor, generally, the capacity C as may be determined in an oscillating circuit is referred to, as the person skilled in the art of electronics generally will recognize. Thus, when implementing the first optical sensor or, alternatively, the second optical sensor into an oscillating circuit, the oscillating circuit, as an example, may have essentially the same resonance frequency. As used herein, the term “essentially identical” generally refers to the fact that, as an example, the capacitance of the first optical sensor and the capacitance of the second optical sensor differ by no more than a factor of 10, more preferably a by no more than a factor of 5 or even by no more than a factor of 2.

10

15

Further, when referring to the capacitance of the second optical sensor, reference is made to the capacitance of the at least one photosensitive element of the second optical sensor, since the photosensitive element determines the electrical behavior and, specifically, the high-frequency behavior of the second optical sensor. In case a plurality of photosensitive elements are present in the second optical sensor, the capacitance of at least one of these photosensitive elements is meant.

20

As outlined above, for example with respect to the first preferred embodiment, for evaluating the first and second sensor signals at least one predetermined or determinable relationship between the first and second sensor signals and the longitudinal coordinate may be used. With respect to evaluation of the first and second sensor signals reference can be made to the description of the first preferred embodiment. Thus, the evaluation device specifically may be configured for deriving a quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals. The evaluation device may be configured for determining the longitudinal coordinate by evaluating the quotient signal Q .

25

30

Typically, in the setup described above, Q may be a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, the quotient $Q = s_1/s_2$ is a monotonously decreasing function of the size of the light spot. This is due to the fact that, in the preferred setup described above, the first light-sensitive area is fully illuminated and preferably is located in the center of the light spot, such as on the optical axis. Consequently, with increasing diameter of the light spot, the peak intensity of the illumination, which mainly may be located in the first light-sensitive area, decreases and, thus, the first sensor signal decreases. The second sensor signal, however, may be more or less independent from the size of the light spot, as long as the light spot, except for the shadow created by the first optical sensor, is located on the second light-sensitive area. Consequently, the second sensor signal may remain more or less constant. The quotient of the first and second sensor

35

40

signals, thus, continuously decreases with increasing diameter of the light beam or diameter of the light spot on the first and second light-sensitive areas. The quotient, further, is mainly independent from the total power of the light beam, since the total power of the light beam forms a factor both in the first sensor signal and in the second sensor signal. Consequently, the quotient

5 Q may form a secondary signal which provides a unique and unambiguous relationship between the first and second sensor signals and the size or diameter of the light beam. Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship

10 between the first and second sensor signals and the longitudinal coordinate may exist. For the latter, reference e.g. may be made to WO 2014/097181 A1. The predetermined relationship may be determined by analytical considerations, such as by assuming a linear combination of Gaussian light beams, by empirical measurements, such as measurements measuring the first and second sensor signals or a secondary signal derived thereof as a function of the longitudinal

15 coordinate of the object, or both.

The first optical sensor and the second optical sensor may be positioned in various ways. Thus, in a first example, the first optical sensor is positioned in front of the second optical sensor, such that the light beam, firstly, passes the first optical sensor and, secondly, thereafter, reaches the

20 second optical sensor. Alternatively, however, a reverse order is possible. Thus, as an alternative, the second optical sensor may be placed in front of the first optical sensor, such that the light beam, firstly, reaches the second optical sensor, fully or partially passes through the second optical sensor and, secondly, thereafter, reaches the first optical sensor. The latter alternative is mainly possible due to the fact that the fluorescent waveguiding sheet of the second optical

25 sensor may, in this embodiment or other embodiments, be embodied fully or partially transparent, specifically in the spectral range of the light beam. Thus, the smaller first optical sensor may be placed on a reverse side of the second optical sensor, from the perspective of the object.

30 The second optical sensor and, more specifically, the fluorescent waveguiding sheet of the second optical sensor, may be placed in various positions in one or more beam paths. Thus, as an example, the second optical sensor and/or the fluorescent waveguiding sheet of the second optical sensor may be placed close to a focal point within a beam path. Alternatively, however, specifically in order to improve the function of summing, the second optical sensor may also be

35 placed away from the focal point, such as by one, two or more than two Rayleigh wavelengths.

As outlined above, the second optical sensor comprises at least one photosensitive element, from which the at least one second sensor signal arises. Therein, precisely one photosensitive

40 element may be used, such as for collecting at least a part of the fluorescence light and for creating a second sensor signal in response. Alternatively, however, the second optical sensor may comprise two, three, four or more photosensitive elements which, preferably, are located at at least two edges of the fluorescent waveguiding sheet, such as at least two opposing portion

of a rim of the fluorescent waveguiding sheet. The photosensitive elements may be capable of detecting fluorescence light guided from the light spot towards the photosensitive elements by the fluorescent waveguiding sheet and capable of generating at least one sensor signal each. Thus, a plurality of second sensor signals may exist.

5

In case at least two photosensitive elements are provided, being located at at least two edges of the fluorescent waveguiding sheet, a plurality of possibilities exists. Thus, as an example, the at least two photosensitive elements may be located at one or more of: at least two straight edges of the fluorescent waveguiding sheet, such as at least two opposing edges, such as opposing rim portions; at least two corners of the fluorescent waveguiding sheet, such as at least two opposing corners; at least one corner of the fluorescent waveguiding sheet and at least one straight edge, such as at least one straight rim portion, of the fluorescent waveguiding sheet. Other possibilities are generally given.

10

15

The detector and, preferably, the evaluation device may specifically be embodied to combine at least two of these second sensor signals to form at least one common second sensor signal. This at least one common second sensor signal, specifically, may be used, in conjunction with the first second sensor signal, for determining the longitudinal coordinate. Additionally, at least one common second sensor signal may be used for acquiring additional information, such as at least one item of information on a transversal position of the object or a part thereof, as will be outlined in further detail below.

20

25

Thus, for combining the at least two second sensor signals, the evaluation device may comprise at least one summing device configured for summing up the sensor signals of the at least two photosensitive elements, thereby forming a sum signal S. As an example, the sum signal may be derived by using the formula

$$S = \sum_i c_i s_i, \quad (1)$$

30

with s_i denoting the second sensor signals, with $i = 1 \dots N$ with N being a positive integer indicating the number of the photosensitive elements or a smaller positive integer, and with c_i being respective calibration coefficients.

35

As outlined above, the evaluation device specifically may be configured to determine the at least one longitudinal coordinate z of the object by using at least one predetermined relationship between the first sensor signal, the at least one second sensor signal and the longitudinal coordinate z. In case a plurality of second sensor signals is given, as outlined above, at least one combined second sensor signal may be used in this relationship. Thus, specifically, the sum signal S may be used. Thus, as an example, the evaluation device may be configured to determine the at least one longitudinal coordinate z by using at least one predetermined relationship between the first sensor signal, the sum signal S of the second sensor signals and the longitudinal coordinate z.

40

In addition to the at least one longitudinal coordinate, the detector may further be configured for determining at least one transversal coordinate of the object and/or of a part thereof. For this purpose, the detector may comprise at least one transversal optical sensor. Various transversal sensors are generally known in the art, such as the transversal sensors disclosed in WO 2014/097181 A1 and/or WO 2014/198629 A1 and/or other position-sensitive devices (PSDs), such as quadrant diodes, CCD or CMOS chips or the like. Thus, as an example, the detector according to the present invention may comprise one or more PSDs disclosed in R.A. Street (Ed.): *Technology and Applications of Amorphous Silicon*, Springer-Verlag Heidelberg, 2010, pp. 346-349. Other embodiments are feasible. As an example, a part of the light beam may be split off within the detector, by at least one beam splitting element. The split-off portion, as an example, may be guided towards a transversal sensor, such as a CCD or CMOS chip or a camera sensor, and a transversal position of a light spot generated by the split-off portion on the transversal sensor may be determined, thereby determining at least one transversal coordinate of the object. Preferably, however, the at least one second optical sensor itself may be used as a transversal optical sensor, for determining at least one transversal coordinate of the object. This setup is specifically advantageous in case a plurality of photosensitive elements is used in the second optical sensor, such as in different positions and located at different edges of the fluorescent waveguiding sheet. The evaluation device may be configured to determine at least one transversal coordinate x , y of the object by evaluating the sensor signals of the photosensitive elements. The evaluation device may be adapted to combine the information of the longitudinal coordinate and the transversal coordinate and to determine a position of the object in space.

Thus, generally, the evaluation device may further be configured to determine at least one transversal coordinate x , y of the object by evaluating the second sensor signals of the photosensitive elements. For the purpose of determining the at least one transversal coordinate in one or more directions, the sensor signals of the photosensitive elements may be compared. Thus, as is evident to the skilled person, the sensor signal of a respective photosensitive element, which represents the fluorescence light guided to the photosensitive elements by the fluorescent waveguiding sheet from the light spot and, thus, from the location of generation of the fluorescence light, depends on a distance between the light spot and the respective photosensitive element. Generally, with an increasing distance between the light spot and the photosensitive element, the sensor signal of the respective photosensitive element will decrease, such as due to losses during waveguiding and/or due to spreading of the fluorescence light. By comparing the sensor signals of the photosensitive elements located at different, known positions, the lateral or transversal position of the light spot on the fluorescent waveguiding sheet may be determined and, therefrom, by using e.g. a known or determinable relationship between the transversal position of the light spot and the transversal coordinate of the object, the transversal coordinate of the object. Again, empirical relationships and/or semiempirical relationships and/or analytical relationships may be used, such as the lens equation which is generally known to the skilled person.

Thus, the evaluation device specifically may be configured for evaluating at least two second sensor signals of at least two different photosensitive elements. As an example, these at least two second sensor signals may be compared in order to determine a transversal position of the light spot on the fluorescent waveguiding sheet and/or for directly deriving a transversal position of the object. Thus, as an example, a difference between at least two second sensor signals may be determined in order to derive at least one item of information on a transversal position of the object. Consequently, the evaluation device may comprise at least one subtracting device configured to form at least one difference signal D between second sensor signals generated by at least two of the photosensitive elements. The second sensor signals may comprise at least one second sensor signal s_{21} and at least one second sensor signal s_{22} , wherein the at least one difference signal D is proportional to $a \cdot s_{21} - b \cdot s_{22}$:

$$D \sim a \cdot s_{21} - b \cdot s_{22}, \quad (2)$$

with a, b being real number coefficients, preferably with $a=1$ and $b=1$. Additionally or alternatively, the at least one difference signal D may be derived according to the formula:

$$D = (a \cdot s_{21} - b \cdot s_{22}) / (a \cdot s_{21} + b \cdot s_{22}). \quad (3)$$

The subtracting device specifically may be configured to form at least one first difference signal D_x from which at least one first transversal coordinate x of the object is derived. Additionally or alternatively, the subtracting device may be further configured to form at least one second difference signal D_y from which at least one second transversal coordinate y of the object is derived. Thus, the first difference signal D_x may be generated from at least two second sensor signals s_{x1} , s_{x2} of at least two photosensitive elements located at opposing edges of the waveguiding sheet in a first dimension. The second difference signal D_y may be generated from at least two second sensor signals s_{y1} , s_{y2} of at least two photosensitive elements located at opposing edges of the waveguiding sheet in a second dimension. The at least one first difference signal D_x may be derived according to the formula

$$D_x = (a \cdot s_{x1} - b \cdot s_{x2}) / (a \cdot s_{x1} + b \cdot s_{x2}), \quad (4)$$

and the at least one second difference signal D_y may be derived according to the formula

$$D_y = (c \cdot s_{y1} - d \cdot s_{y2}) / (c \cdot s_{y1} + d \cdot s_{y2}), \quad (5)$$

with a, b, c, d being real number coefficients, preferably with $a=1$, $b=1$, $c=1$ and $d=1$.

As outlined above, in case the second optical sensor comprises a plurality of photosensitive elements, the second optical sensor specifically may comprise at least two photosensitive elements located at opposing edges of the fluorescent waveguiding sheet. The photosensitive elements may comprise at least one first pair of photosensitive elements located at opposing edges of the fluorescent waveguiding sheet in a first dimension of a coordinate system, and the

photosensitive elements may further comprise at least one second pair of photosensitive elements located at opposing edges of the fluorescent waveguiding sheet in a second dimension of the coordinate system.

- 5 Further optional details may refer to the at least one fluorescent waveguiding sheet and/or to the second light-sensitive area. Thus, as an example, the second light-sensitive area specifically may be a homogeneous light-sensitive area. Thus, the second light-sensitive area may not be subdivided physically into partial areas, such as pixels. Contrarily, the sensitive area may be one homogeneous area which forms a uniform fluorescence.

10

The second light-sensitive area specifically may be a large sensitive area. Thus, as an example, the second light-sensitive area may have a surface of at least 5 mm², preferably of at least 10 mm², more preferably of at least 100 mm², more preferably of at least 400 mm². As an example, the sensitive area may have a surface of 5 mm² to 10,000 mm², such as 100 mm² to 2500 mm².

15

The large-area design of the sensitive area is advantageous in many ways. Thus, specifically, by increasing the surface of the second light-sensitive area, a resolution of the determination of the transversal coordinates may be increased. Further, the field of view of the detector, e.g. the viewing angle, may be widened by using a large second light-sensitive area.

20

The fluorescent waveguiding sheet specifically may comprise at least one planar sheet. Therein, however, slight curvatures still may be tolerated. In other embodiments, however, the fluorescent waveguiding sheet may also be embodied as a curved fluorescent waveguiding sheet, such as in order to provoke specific optical effects which might be desirable in certain applications. Thus, one of the advantages of the present detector may reside in the fact that the fluorescent waveguiding sheet specifically may be curved, flexible or having a specific geometry.

25

The fluorescent waveguiding sheet may have a thickness of 10 µm to 3 mm, preferably a thickness of 100 µm to 1 mm, e.g. a thickness of 50 µm to 2 mm. The thickness of the waveguiding sheet specifically may be dimensioned of the waveguiding sheet along an optical axis of the detector. The thickness may be adapted to improve or optimize waveguiding properties of the fluorescence light.

30

The fluorescent waveguiding sheet may fully or partially be rigid or, alternatively, may fully or partially be embodied flexible or deformable.

35

The fluorescent waveguiding sheet may comprise at least one matrix material. As used herein, the term "matrix material" generally refers to a material which forms the main part of the fluorescent waveguiding sheet and which defines the main body of the fluorescent waveguiding sheet. As an example, the matrix material may be a material which is capable of receiving one or more additional materials therein, such as by intermixing, chemical bonding, dispersion or solving. Thus, the at least one fluorescent material may be one or more mixed into the matrix material, dispersed into the matrix material, chemically bound to the matrix material or dissolved in the matrix material.

40

The matrix material specifically may be or may comprise at least one plastic material. The plastic material specifically may be or may comprise at least one polymer material. The plastic material, as an example, may be or may comprise at least one material selected from the group consisting of a polycarbonate, a poly(methyl methacrylate), a polystyrene, a polyurethane, a polypropylene, a polyethylene terephthalate, a polyvinylchloride. Other materials, however, are feasible.

The fluorescent material specifically may comprise an arbitrary fluorophore. Specifically, the at least one fluorescent material may comprise at least one fluorescent dye. A wide variety of fluorescent dyes is generally known to the skilled person. Thereof, as outlined above, most of these fluorescent dyes exhibit the above-mentioned saturation effects, thereby rendering the fluorescence being a nonlinear function of the excitation. As an example, the fluorescent dye may be capable of being saturated by the light beam, such that a total power of the fluorescence light generated by the fluorescent dye is a nonlinear function of an intensity of the light beam. Specifically, the total power of the fluorescence light may be sub-proportional to the intensity of the light beam.

The fluorescent dye specifically may comprise at least one organic fluorescent dye. Inorganic dyes, however, may be used additionally or alternatively. The fluorescent dye specifically may be selected from the group consisting of: a xanthene derivative, preferably one or more of fluorescein, rhodamine, oregon green, eosin, texas red, or a derivative of any component thereof; a cyanine derivative, preferably one or more of cyanine, indocarbocyanine, oxacarbocyanine, thiocarbocyanine, merocyanine, or a derivative of any component thereof; a squaraine derivative or a ring-substituted squaraine, preferably one or more of Seta, SeTau, and Square dyes, or a derivative of any component thereof; a naphthalene derivative, preferably one or more of a dansyl or a prodan derivative thereof; a coumarin derivative; a oxadiazole derivative, preferably one or more of pyridyloxazole, nitrobenzoxadiazole, benzoxadiazole, or a derivative of any component thereof; an anthracene derivative, preferably one or more of an anthraquinone, DRAQ5, DRAQ7, CyTRAK orange, or a derivative of any component thereof; a pyrene derivative, preferably cascade blue; an oxazine derivative, preferably one or more of nile red, nile blue, cresyl violet, oxazine 170, or a derivative of any component thereof; an acridine derivative, preferably one or more of proflavin, acridine orange, acridine yellow, or a derivative of any component thereof; an arylmethine derivative, preferably one or more of auramine, crystal violet, malachite green, or a derivative of any component thereof; a tetrapyrrole derivative, preferably one or more of porphin, phthalocyanine, bilirubin; a rylene dye or any derivative thereof, such as a perylene dye; a naphthalene imid or perylene imide; a naphthoilene benzimidazole dye such as published in WO 2012/168395 A1; or a derivative of any component of the listed substances. It shall be noted, however, that other dyes may be used additionally or alternatively.

Further optional details of the detector referred to the at least one photosensitive element or to the plurality of photosensitive elements. Thus, as an example, the at least one photosensitive element may comprise at least one photodiode, preferably at least one inorganic photodiode, such as a silicon photodiode. The at least one photosensitive element may comprise at least

one elongated photosensitive element extending along at least one segment of an edge or rim portion of the waveguiding sheet.

5 As outlined above, the fluorescent waveguiding sheet specifically may be a rectangular fluorescent waveguiding sheet, preferably a square waveguiding sheet. In the setup, as an example, the photosensitive elements may be located at each of the four edges, such as at each of the four straight rim sections or rim portions, of the waveguiding sheet. Other embodiments are feasible.

10 The first and second optical sensors each, independently, may be opaque, transparent or semi-transparent. For the sake of simplicity, however, opaque sensors which are not transparent for the light beam, may be used, since these opaque sensors generally are widely commercially available. The fluorescent waveguiding sheet, however, may fully or partially be transparent.

15 The first optical sensor specifically may be a uniform sensor having a uniform light-sensitive area. Thus, specifically, the first optical sensor specifically may be a non-pixelated optical sensor. Alternatively, however, the at least one first optical sensor may also comprise one or more pixelated sensors, each having two or more pixels. Other embodiments are feasible.

20 Similarly, as discussed in further detail below, the at least one second optical sensor may comprise precisely one second optical sensor or a plurality of optical sensors. Further, the at least one fluorescent waveguiding sheet of the second optical sensor may be precisely one coherent fluorescent waveguiding sheet. Alternatively, however, the at least one second optical sensor also may comprise a plurality of second optical sensors. The latter alternative, as an example,
25 may be realized by providing a plurality of fluorescent waveguiding sheets. Thus, a plurality of fluorescent waveguiding sheets may be provided, each having one or more photosensitive elements. Other embodiments are feasible.

The detector, such as of the second optical sensor, may further comprise at least one optical
30 filter element, preferably at least one optical short-pass filter. Thus, as an example, only photons which are capable of exciting fluorescence light may pass through to the fluorescent waveguiding sheet. Other embodiments, however, are feasible.

The first and second optical sensors specifically may be arranged linearly in one and the same
35 beam path of the detector. Thus, as an example, the first and second optical sensors may be arranged concentrically with respect to an optical axis of the detector, specifically with the first optical sensor being placed in front of the second optical sensor. It shall be noted, however, that other embodiments are feasible, such as embodiments with the first optical sensor and the second optical sensor being placed in separate and different beam paths, wherein the beam path of
40 the detector is split by one or more beam-splitting elements. The linear setup with the first and second optical sensors being placed in one and the same beam path, however, is preferred, due to the simple optical setup and the low volume required for the detector. Thus, the present invention specifically allows for a simple, efficient and inexpensive optical setup.

As outlined above, the first optical sensor specifically may be a semiconductor sensor, preferably an inorganic semiconductor sensor, more preferably a photodiode and most preferably a silicon photodiode. As an example, the first optical sensor may be a uniform sensor having a single light-sensitive area. As an example, a commercially available silicon photodiode may be used.

In a further preferred embodiment the detector may comprise

- at least one angle dependent optical element adapted to generate at least one light beam having at least one beam profile depending on an angle of incidence of an incident light beam propagating from the object towards the detector and illuminating the angle dependent optical element;
- at least two optical sensors, wherein each optical sensor has at least one light sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by the light beam generated by the angle dependent optical element;
- the at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating the quotient signal Q from the sensor signals.

The angle dependent optical element may comprise at least one optical element selected from the group consisting of: at least one optical fiber, in particular at least one multifurcated optical fiber, in particular at least one bifurcated optical fiber; at least one diffractive optical element, at least one angle dependent reflective element, at least one diffractive grating element, in particular a blaze grating element; at least one aperture stop; at least one prism; at least one lens; at least one lens array, in particular at least one microlens array; at least one optical filter; at least one polarization filter; at least one bandpass filter; at least one liquid crystal filter, in particular a liquid crystal tunable filter; at least one short-pass filter; at least one long-pass filter; at least one notch filter; at least one interference filter; at least one transmission grating; at least one nonlinear optical element, in particular one birefringent optical element.

At least one of the light-sensitive areas may be oriented towards the object. Specifically, at least one interconnecting line between at least one point of the object and at least one point of the respective light-sensitive area may form an angle with a surface element of the light-sensitive area which is different from 0° , such as an angle in the range of 20° to 90° , preferably 80° to 90° such as 90° . Thus, when the object is located on the optical axis or close to the optical axis, the light beam propagating from the object towards the detector may be essentially parallel to the optical axis. Additionally or alternatively, at least one of the light-sensitive areas may be oriented differing from an orientation towards the object. For example, at least one of the optical sensors may be oriented perpendicular or under an arbitrary angle to the optical axis and with respect to the object. The angle dependent optical element may be adapted to generate the light beam such that the light beam impinges on the light-sensitive areas. For example, in case at least one of the light-sensitive areas is oriented under the arbitrary angle with respect to the optical axis,

the angle dependent optical element may be adapted to guide the light beam onto the light-sensitive area.

As used herein, the term “angle dependent optical element” refers to an optical element adapted to generate the at least one light beam having at least one beam profile depending on the angle of incidence of the incident light beam propagating from the object towards the detector and illuminating the angle dependent optical element. In particular, the angle dependent optical element may be adapted to influence and/or change and/or adjust the beam profile of the incident light beam. For example, the angle dependent optical element may have one or more of angle dependent transmission properties, angle dependent reflection properties or angle dependent absorption properties. The light beam generated by the angle dependent optical element may comprise at least one transmission light beam and/or at least one reflection light beam. The angle of incidence may be measured with respect to an optical axis of the angle dependent optical element.

An electromagnetic wave impinging on a first side, for example a surface and/or an entrance, of the angle dependent optical element may be partly, depending on the properties of the angle dependent optical element, absorbed and/or reflected and/or transmitted. The term “absorption” refers to a reduction of power and/or intensity of the incident light beam by the angle dependent optical element. For example, the power and/or intensity of the incident light beam may be transformed by the angle dependent optical element to heat or another type of energy. As used herein, the term “transmission” refers to a part of the electromagnetic wave which is measurable outside the angle dependent optical element in a half-space with angles from 90° and higher with respect to the optical axis. For example, transmission may be a remaining part of the electromagnetic wave impinging on the first side of the angle dependent optical element, penetrating the angle dependent optical element and leaving the angle dependent optical element at a second side, for example an opposite side and/or an exit. The term “reflection” refers to a part of the electromagnetic wave which is measurable outside the angle dependent optical element in a half-space with angles below 90° with respect to the optical axis. For example, reflection may be a change in direction of a wavefront of the incident light beam due to interaction with the angle dependent optical element.

The total power of the electromagnetic wave impinging on the angle dependent optical element may be distributed by the angle dependent optical element in at least three components, i.e. an absorption component, a reflection component and a transmission component. A degree of transmission may be defined as power of the transmission component normalized by the total power of the electromagnetic wave impinging on the angle dependent optical element. A degree of absorption may be defined as power of the absorption component normalized by the total power of the electromagnetic wave impinging on the angle dependent optical element. A degree of reflection may be defined as power of the reflection component normalized by the total power of the electromagnetic wave impinging on the angle dependent optical element.

As used herein, "angle dependent transmission" refers to the fact that the degree of transmission depends on the angle of incidence at which the incident light beam propagating from the object towards the detector impinges on the angle dependent optical element. As outlined above, the angle of incident may be measured with respect to an optical axis of the angle dependent optical element. The angle dependent optical element may be arranged in the direction of propagation behind at least one transfer device. The transfer device may, for example, comprise at least one collimating lens. The angle dependent optical element may be designed to weaken rays impinging with larger angles compared to rays impinging with a smaller angle. For example, the degree of transmission may be highest for light rays parallel to the optical axis, i.e. at 0°, and may decrease for higher angles. In particular, at at least one cut-off angle the degree of transmission may steeply fall to zero. Thus, light rays having a large angle of incidence may be cut-off.

As used herein, the term "angle dependent absorption" refers to the fact that the degree of absorption depends on the angle of incidence at which the incident light beam propagating from the object towards the detector impinges on the angle dependent optical element. As used herein, the term "angle dependent absorption" refers to the fact that a degree of absorption depends on the angle of incidence at which the incident light beam propagating from the object towards the detector impinges on the angle dependent optical element. For example, photon energy and/or intensity of the light beam propagating from the object to the detector may be reduced depending on the angle of incidence.

As used herein, the term "angle dependent reflection" refers to the fact that the degree of reflection depends on the angle of incidence at which the incident light beam propagating from the object towards the detector impinges on the angle dependent optical element.

For example, the angle dependent optical element comprises at least one optical fiber. The optical fiber may be designed such that the degree of transmission may be highest for incoming light rays parallel, i.e. at an angle of 0°, to the optical fiber, neglecting reflection effects. The optical fiber may be designed such that for higher angles, for example angles from 1° to 10°, the degree of transmission may decrease smoothly to around 80% of the degree of transmission for parallel light rays and may remain at this level constantly up to an acceptance angle of the optical fiber. As used herein, the term "acceptance angle" may refer to an angle above which total reflection within the optical fiber is not possible such that the light rays are reflected out of the optical fiber. The optical fiber may be designed that at the acceptance angle, the degree of transmission may steeply fall to zero. Light rays having a large angle of incidence may be cut-off.

The optical fiber may be adapted to transmit at least parts of the incident light beam which are not absorbed and/or reflected, between two ends of the optical fiber. The optical fiber may have a length and may be adapted to permit transmission over a distance. The optical fiber may comprise at least one material selected from the group consisting of: silica, aluminosilicate glass, germane silicate glass, fluorozirconate, rare earth doped glass, fluoride glass, chalco-

genide glasses, sapphire, doped variants, especially for silica glass, phosphate glass, PMMA, polystyrene, fluoropolymers such as poly(perfluoro-butenylvinyl ether), or the like. The optical fiber may be a single or multi-mode fiber. The optical fiber may be a step index fiber, a polarizing fiber, a polarization maintaining fiber, a plastic optical fiber or the like. The optical fiber may
5 comprise at least one fiber core which is surrounded by at least one fiber cladding having a lower index of refraction as the fiber core. The fiber cladding may also be a double or multiple cladding. The fiber cladding may comprise a so-called outer jacket. The fiber cladding may be coated by a so-called buffer adapted to protect the optical fiber from damages and moisture. The buffer may comprise at least one UV-cured urethane acrylate composite and/or at least one
10 polyimide material. In one embodiment, a refractive index of the fiber core may be higher than the refractive index of the fiber cladding material and the optical fiber may be adapted to guide the incoming light beam by total internal reflection below the angle of acceptance. In one embodiment, the optical fiber may comprise at least one hollow core fiber, also called photonic bandgap fiber. The hollow-core fiber may be adapted to guide the incoming light beam essentially
15 within a so-called hollow region, wherein a minor portion of the light beam is lost due to propagation into the fiber cladding material.

The optical fiber may comprise one or more fiber connectors at the end of the fiber. The optical fiber may comprise end caps such as coreless end caps. The optical fiber may comprise one or
20 more of a fiber coupler, a fiber Bragg grating, a fiber polarizer, a fiber amplifier, a fiber coupled diode laser, a fiber collimator, a fiber joint, a fiber splicing, a fiber connector, a mechanical splicing, a fusion splicing, or the like. The optical fiber may comprise a polymer coating.

The optical fiber may comprise at least two or more fibers. The optical fiber may be at least one
25 multifurcated optical fiber, in particular at least one bifurcated optical fiber. For example, the bifurcated optical fiber may comprise two fibers, in particular at least one first fiber and at least one second fiber. The first fiber and the second fiber may be arranged close to each other at an entrance end of the bifurcated optical fiber and may split into two legs separated by a distance at an exit end of the bifurcated optical fiber. The first and second fiber may be designed as fi-
30 bers having identical properties or may be fibers of different type. The first fiber may be adapted to generate at least one first transmission light beam and the second fiber may be adapted to generate at least one second transmission light beam. The bifurcated optical fiber may be arranged such that the incident light beam may impinge at a first angle of incidence into the first fiber and at a second angle of incidence, different from the first angle, into the second fiber,
35 such that the degree of transmission is different for the first transmission light beam and the second transmission light beam. One of the optical sensors may be arranged at an exit end of the first fiber and the other optical sensor may be arranged at an exit end of the second fiber. The optical fiber may comprise more than two fibers, for example three, four or more fibers. For example, the multifurcated may comprise multiple fibers wherein each fiber may comprise at
40 least one of a core, a cladding, a buffer, a jacket, and one or more fibers may partially or entirely be bundled by a further jacket such as a polymer hose to ensure that the fibers stay close to each other such as at one end of the fiber.

The detector may comprise a plurality of optical fibers, for example a plurality of single optical fibers or a plurality of multifurcated optical fibers. For example, the detector may comprise a plurality of single optical fibers, for example optical fibers having identical properties. The optical fibers, i.e. the single optical fibers or multifurcated optical fibers, may be arranged such that the incident light beam may impinge at different angles of incidence into each of the optical fibers such that the degree of transmission is different for each of the optical fibers. At the exit ends of each optical fiber at least one optical sensor may be arranged. Alternatively, at least two or more of the optical fibers may use the same optical sensor.

The illumination source may be adapted to illuminate the object through the angle dependent optical element. The optical fiber may comprise at least one illumination fiber adapted to transmit at least one incoming light beam generated by the illumination source such that it illuminates the object. The illumination source may be adapted to couple the at least one light beam generated by the illumination source into the illumination fiber. The detector may comprise at least one coupling element, for example at least one in-coupling element and/or at least one out-coupling element, which may be arranged in front of and/or behind the optical fiber. The coupling element may be or may comprise at least one transfer device.

The detector may comprise a further coupling element, in particular a further in-coupling element, adapted to couple the light beam travelling from the object to the detector into the illumination fiber. The further coupling element may be arranged in direction of propagation of the light beam travelling from the object to the detector in front of the optical fiber. The further coupling element may be or may comprise at least one transfer device.

In case the detector comprises a plurality of optical fibers, the detector may comprise one illumination source or a plurality of identical illumination sources and/or a plurality of different illumination sources. For example, the plurality of illumination sources may comprise at least two illumination sources generating light with different properties such as color or modulation frequencies. In one embodiment, at least two of the optical fibers of the plurality of the optical fibers may be illuminated using the same illumination source and/or two identical illumination sources. At the exit ends of each optical fiber illuminated by the same illumination source and/or by identical illumination sources at least one optical sensor may be arranged. Alternatively, at least two or more of the optical fibers illuminated by the same illumination source may use the same optical sensor. Such a detector, in which for a plurality of optical fibers the same illumination source and same optical sensors are used, may be used as proximity sensor. In one embodiment, at least two of the optical fibers of the plurality of optical fibers may be illuminated by using at least two different illumination sources. At the exit ends of each optical fiber at least one optical sensor may be arranged. Alternatively, at least two or more of the optical fibers may use the same optical sensor.

As outlined above, the distance perpendicular to an optical axis of the detector between the illumination source and the optical sensors may be small. The baseline may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. For example, the baseline may

be 21 mm. In particular in case the angle dependent optical element is an optical fiber, the baseline may even be smaller than a radius of the transfer device.

For example, the angle dependent optical element may be an optical fiber. The illumination
5 source may be guided through an optical fiber wherein the illumination beam may exit the optical fiber behind the transfer device within a baseline that is smaller than the radius of the transfer device. The illumination source may be adapted to generate at least one illumination light beam, wherein the optical fiber guiding the illumination beam may be attached to the transfer device such as by a polymer or glue or the like, to reduce reflections at interfaces with larger
10 differences in refractive index. For example, the detector may be a compact device without further optical elements, wherein the illumination source may be placed as close as possible to an edge of the transfer device. Thus, the baseline may be close to half a diameter of the transfer device, in particular the lens diameter and housings of lens and light source. For example, the detector may be an even more compact device, wherein a mirror, in particular a small mirror,
15 may be positioned in front of the transfer device, in particular in a center, for example a geometrical center, or close to the center of the transfer device, in order to couple the illumination beam into the beam path. Thus, the baseline may be less than half the diameter of the transfer device. The illumination source may be arranged such that the baseline is as small as possible. By arranging the illumination source such that the direction of propagation of the illumination light
20 beam is essentially parallel to the optical axis and that the illumination source and the optical axis are separated by the small baseline, very compact devices are possible. For example, a distance from the center of the transfer device to the illumination source, in particular along a connecting line from the center of the transfer device to the illumination source, may be preferably less than 2.5 times a distance from the center of the transfer device to an edge if the transfer
25 device, more preferably less than 1.5 times the distance center to edge of the transfer device, and most preferably less 1 times the distance center to edge of the transfer device. The transfer device may have an arbitrary shape, in particular a non-circular shapes are possible. At small distances an aperture of the illumination source may be small and the baseline may be small. At large distances an aperture of the illumination source may be large and the baseline may be
30 small. This is contrarily as in triangulation methods, wherein at large distances a large baseline is necessary. Further, triangulation based systems have a minimum detection range significantly greater than zero, for example such as 20 cm from the detector system, due to necessary spatial extend of the baseline. Such a large baseline may result in that the illuminated light scattered from the object may not reach the light sensitive area of the optical sensor behind the
35 transfer device. In addition, in triangulation based systems, using a small baseline would reduce the minimum detection range, however, at the same time would reduce a maximum detection range. Further, triangulation based systems require a plurality of light sensitive areas and sensor signals, for example sensor signals of at least one detector row. According to the invention, determination of the longitudinal coordinate z is possible with a reduced number of sensor signals, in particular with less than 20, preferably less than 10 and more preferably less than 5
40 sensor signals. The illumination source and the angle dependent optical element may be arranged in the direction of propagation of the light beam traveling from the object to the detector behind the transfer device, which will be described in detail below. The distance perpendicular

to the optical axis of the detector between the illumination source and the optical sensors may be less than the radius of the transfer device.

5 The illumination source and the optical sensors and/or the illumination source and the angle dependent optical element and/or the optical sensors may be arranged with a relative spatial offset from the optical axis of the detector. Such an arrangement may allow enhancing the tendency of the quotient, and thus, accuracy of the distance measurement. In particular, with increasing spatial offset a slope in a Q vs distance diagram increases and thus allows distinguishing similar distances more accurately. For example, one of the illumination source and the optical sensors may be arranged on the optical axis and the other one may be arranged spaced apart from the optical axis. For example, both of illumination source and the optical sensors may be arranged spaced apart from the optical axis by at least one different distance, in particular perpendicular to the optical axis. For example, the at least two fibers of a multifurcated optical fiber may be arranged at different distances from the optical axis. The angle dependent optical element is adapted to mimic a larger distance compared to the real distance perpendicular to an optical axis between the illumination source and the optical sensors without moving the illumination source and/or optical sensors.

20 By way of example, the transfer device can have one or more lenses, in particular one or more refractive lenses, and/or one or more convex mirrors. In this example, the focal length may be defined as a distance from the center of the thin refractive lens to the principal focal points of the thin lens. For a converging thin refractive lens, such as a convex or biconvex thin lens, the focal length may be considered as being positive and may provide the distance at which a beam of collimated light impinging the thin lens as the transfer device may be focused into a single spot. Additionally, the transfer device can comprise at least one wavelength-selective element, for example at least one optical filter. Additionally, the transfer device can be designed to impress a predefined beam profile on the electromagnetic radiation, for example, at the location of the sensor region and in particular the sensor area. The abovementioned optional embodiments of the transfer device can, in principle, be realized individually or in any desired combination.

30 Alternatively to the linear arrangement of the two optical sensors, the optical sensors may be arranged in different beam paths of the detector. The angle dependent optical element may be adapted to generate the first light beam and the second light beam. The first light beam and the second light beam may be generated with different degree of transmission. The first optical sensor may be configured to generate the first sensor signal in response to the illumination of the first light-sensitive area by the first light beam generated by the angle dependent optical element. The second optical sensor may be configured to generate the second sensor signal in response to the illumination of the second light-sensitive area by the second light beam generated by the angle dependent optical element. For example, as outlined above, the angle dependent optical element may comprise at least one multifurcated optical fiber which may be arranged such that the incident light beam may impinge at the first angle of incidence into the first fiber and at the second angle of incidence, different from the first angle, into the second fiber, such that the degree of transmission is different for the first light beam, in this case a first

transmission light beam, and the second light beam, in this case a second transmission light beam. One of the first and second optical sensors may be arranged at the exit end of the first fiber and the other optical sensor may be arranged at the exit end of the second fiber.

- 5 At least one sensor element may have a matrix of optical sensors, wherein the optical sensors each having a light-sensitive area, wherein each optical sensor may be configured to generate at least one sensor signal in response to an illumination of the light-sensitive area by the light beam generated by the angle dependent optical element.
- 10 For example, the detector may comprise two sensor elements, in particular at least one first sensor element and at least one second sensor element, arranged in different beam paths of the detector. The angle dependent optical element may be adapted to generate the first light beam and the second light beam. The first light beam and the second light beam may be generated with different degree of transmission. The first sensor element may be configured to
- 15 generate the first sensor signal in response to the illumination by the first light beam generated by the angle dependent optical element. The second sensor element may be configured to generate the second sensor signal in response to an illumination by the second light beam generated by the angle dependent optical element. For example, as outlined above, the angle dependent optical element may comprise at least one multifurcated optical fiber arranged such that the
- 20 incident light beam may impinge at the first angle of incidence into the first fiber and at the second angle of incidence, different from the first angle, into the second fiber, such that the degree of transmission is different for the first transmission light beam and the second transmission light beam. One of the first and second sensors elements may be arranged at the exit end of the first fiber and the other sensor element may be arranged at the exit end of the second fiber.
- 25 The detector may comprise at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different spatial offsets, wherein each optical sensor is configured to generate a sensor signal in
- 30 response to an illumination of its respective light-sensitive area by the light beam generated by the angle dependent optical element.

The evaluation device may be configured for determining at least one longitudinal coordinate z of the object by combining the at least two sensor signals. In this further embodiment the optical

35 sensors may be arranged such that the light-sensitive areas of the optical sensors differ in their spatial offset and/or their surface areas

The detector may have a single beam path along which a light beam may travel from the object to the optical sensors, or may have a plurality of beam paths. For example, in case the angle

40 dependent optical element comprises at least one multifurcated optical fiber, each of the fibers of the multifurcated optical fiber may constitute an independent beam path. As an example, a single beam path may be given or the beam path may be split into two or more partial beam paths. In the latter case, each partial beam path may have its own optical axis, and the condi-

tion noted above generally may refer to each beam path independently. The optical sensors may be located in one and the same beam path or partial beam path. Alternatively, however, the optical sensors may also be located in different partial beam paths. In case the optical sensors are distributed over different partial beam paths, the above-mentioned condition may be described such that at least one first optical sensor is located in at least one first partial beam path, being offset from the optical axis of the first partial beam path by a first spatial offset, and at least one second optical sensor is located in at least one second partial beam path, being offset from the optical axis of the second partial beam path by at least one second spatial offset, wherein the first spatial offset and the second spatial offset are different.

As outlined above, each light-sensitive area has a geometrical center. Each geometrical center of each light-sensitive area may be spaced apart from the optical axis of the detector, such as the optical axis of the beam path or the respective beam path in which the respective optical sensor is located.

As outlined above, the optical sensors specifically may be located in one and the same plane, which, preferably, is a plane perpendicular to the optical axis. Other configurations, however, are possible. Thus, two or more of the optical sensors may also be spaced apart in a direction parallel to the optical axis.

For example, the optical sensors may be partial diodes of a segmented diode, with a center of the segmented diode being off-centered from the optical axis of the detector. As an example, bi-cell diodes or quadrant diodes are widely commercially available at low cost, and driving schemes for these bi-cell diodes or quadrant diodes are generally known. As an example, the bi-cell diodes may each form independent diodes having the full functionality of a diode. As an example, each of the bi-cell diodes may have a square or rectangular shape, and the two diodes may be placed in one plane such that the two partial diodes, in total, form a 1 x 2 or 2 x 1 matrix having a rectangular shape. In the present invention, however, a new scheme for evaluating the sensor signals of the bi-cell diodes and quadrant diode is proposed, as will be outlined in further detail below. Generally, however, the optical sensors specifically may be partial diodes of a quadrant diode, with a center of the quadrant diode being off-centered from the optical axis of the detector. As an example, the four partial diodes may each form independent diodes having the full functionality of a diode. As an example, the four partial diodes may each have a square or rectangular shape, and the four partial diodes may be placed in one plane such that the four partial diodes, in total, form a 2 x 2 matrix having a rectangular or square shape. In a further example, the four partial diodes, in total, may form a 2 x 2 matrix having a circular or elliptical shape. The partial diodes, as an example, may be adjacent, with a minimum separation from one another.

In case a quadrant diode is used, having a 2x2 matrix of partial diodes, the center of the quadrant diode specifically may be off-centered or offset from the optical axis. Thus, as an example, the center of the quadrant diodes, which may be an intersection of the geometrical centers of the optical sensors of the quadrant diode, may be off-centered from the optical axis by at least

0.2 mm, more preferably by at least 0.5 mm, more preferably by at least 1.0 mm or even 2.0 mm. Similarly, when using other types of optical sensors setups having a plurality of optical sensors, an overall center of the optical sensors may be offset from the optical axis by the same distance.

5

In a further aspect of the present invention, a detector system for determining a position of at least one object is disclosed. The detector system comprises at least one detector according to the present invention, such as according to one or more of the embodiments disclosed above or according to one or more of the embodiments disclosed in further detail below. The detector
10 system further comprises at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object. Further details regarding the beacon device will be given below, including potential embodiments thereof. Thus, the at least one beacon device may be or may comprise at least one active beacon device, comprising one or more
15 illumination sources such as one or more light sources like lasers, LEDs, light bulbs or the like. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Alternatively, as outlined above, the infrared spectral range may be used, such as in the range of 780 nm to 3.0 μm . Specifically, the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm may be used. The light emitted by the
20 one or more beacon devices may be non-modulated or may be modulated, as outlined above, in order to distinguish two or more light beams. Additionally or alternatively, the at least one beacon device may be adapted to reflect one or more light beams towards the detector, such as by comprising one or more reflective elements. Further, the at least one beacon device may be or may comprise one or more scattering elements adapted for scattering a light beam. Therein,
25 elastic or inelastic scattering may be used. In case the at least one beacon device is adapted to reflect and/or scatter a primary light beam towards the detector, the beacon device may be adapted to leave the spectral properties of the light beam unaffected or, alternatively, may be adapted to change the spectral properties of the light beam, such as by modifying a wavelength of the light beam.

30

In a further aspect of the present invention, a human-machine interface for exchanging at least one item of information between a user and a machine is disclosed. The human-machine interface comprises at least one detector system according to the embodiments disclosed above and/or according to one or more of the embodiments disclosed in further detail below. Therein,
35 the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user or held by the user. The human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to assign to the position at least one item of information.

40

In a further aspect of the present invention, an entertainment device for carrying out at least one entertainment function is disclosed. The entertainment device comprises at least one human-machine interface according to the embodiment disclosed above and/or according to one or more of the embodiments disclosed in further detail below. The entertainment device is config-

ured to enable at least one item of information to be input by a player by means of the human-machine interface. The entertainment device is further configured to vary the entertainment function in accordance with the information.

- 5 In a further aspect of the present invention, a tracking system for tracking a position of at least one movable object is disclosed. The tracking system comprises at least one detector system according to one or more of the embodiments referring to a detector system as disclosed above and/or as disclosed in further detail below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time.

In a further aspect of the present invention, a camera for imaging at least one object is disclosed. The camera comprises at least one detector according to any one of the embodiments referring to a detector as disclosed above or as disclosed in further detail below.

15

- In a further aspect of the present invention, a readout device for optical storage media is proposed. The readout device comprises at least one detector according to any one of the preceding embodiments referring to a detector. As used therein, a readout device for optical storage media generally refers to a device which is capable of optically retrieving information stored in optical storage media such as optical storage discs, e.g. CCD, DVD or Blu-ray discs. Thus, the above-described measurement principle of the detector according to the present invention may be used for detecting data modules within an optical storage medium such as in optical storage discs. As an example, in case a reflective data module is present and reflects the illuminating light beam, the detector will not only detect the reflected light beam according to the above-mentioned measurement principle but will also detect a distance between the detector and the reflective data module, i.e. a depth of the reflective data module within the optical storage medium. Thus, as an example, the detector may be used for detecting different layers of information modules or data modules within the optical storage medium. Thereby, as an example, two layer discs or three layer discs or even discs having more than three layers may be generated and read out.

30

- In a further aspect of the present invention, a scanning system for determining a depth profile of a scenery, which may also imply determining at least one position of at least one object, is provided. The scanning system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The scanning system further comprises at least one illumination source adapted to scan the scenery with at least one light beam, which may also be referred to as an illumination light beam or scanning light beam. As used herein, the term "scenery" generally refers to a two-dimensional or three-dimensional range which is visible by the detector, such that at least one geometric or spatial property of the two-dimensional or three-dimensional range may be evaluated with the detector. As further used herein, the term "scan" generally refers to a consecutive measurement in different regions. Thus, the scanning specifically may imply at least one first measurement with the illumination

35

40

light beam being oriented or directed in a first fashion, and at least one second measurement with the illumination light beam being oriented or directed in a second fashion which is different from the first fashion. The scanning may be a continuous scanning or a stepwise scanning.

Thus, in a continuous or stepwise fashion, the illumination light beam may be directed into different regions of the scenery, and the detector may be detected to generate at least one item of information, such as at least one longitudinal coordinate, for each region. As an example, for scanning an object, one or more illumination light beams may, continuously or in a stepwise fashion, create light spots on the surface of the object, wherein longitudinal coordinates are generated for the light spots. Alternatively, however, a light pattern may be used for scanning.

The scanning may be a point scanning or a line scanning or even a scanning with more complex light patterns. The illumination source of the scanning system may be distinct from the optional illumination source of the detector. Alternatively, however, the illumination source of the scanning system may also be fully or partially identical with or integrated into the at least one optional illumination source of the detector.

Thus, the scanning system may comprise at least one illumination source which is adapted to emit the at least one light beam being configured for the illumination of the at least one dot located at the at least one surface of the at least one object. As used herein, the term "dot" refers to an area, specifically a small area, on a part of the surface of the object which may be selected, for example by a user of the scanning system, to be illuminated by the illumination source. Preferably, the dot may exhibit a size which may, on one hand, be as small as possible in order to allow the scanning system to determine a value for the distance between the illumination source comprised by the scanning system and the part of the surface of the object on which the dot may be located as exactly as possible and which, on the other hand, may be as large as possible in order to allow the user of the scanning system or the scanning system itself, in particular by an automatic procedure, to detect a presence of the dot on the related part of the surface of the object.

For this purpose, the illumination source may comprise an artificial illumination source, in particular at least one laser source and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Additionally or alternatively, light in the infrared spectral range may be used, such as in the range of 780 nm to 3.0 μm . Specifically, the light in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm may be used. On account of their generally defined beam profiles and other properties of handleability, the use of at least one laser source as the illumination source is particularly preferred. Herein, the use of a single laser source may be preferred, in particular in a case in which it may be important to provide a compact scanning system that might be easily storable and transportable by the user. The illumination source may thus, preferably be a constituent part of the detector and may, therefore, in particular be integrated into the detector, such as into the housing of the detector. In a preferred embodiment, particularly the housing of the scanning system may comprise at least one display configured for providing distance-

related information to the user, such as in an easy-to-read manner. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least one button which may be configured for operating at least one function related to the scanning system, such as for setting one or more operation modes. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least one fastening unit which may be configured for fastening the scanning system to a further surface, such as a rubber foot, a base plate or a wall holder, such as a base plate or holder comprising a magnetic material, in particular for increasing the accuracy of the distance measurement and/or the handleability of the scanning system by the user.

Particularly, the illumination source of the scanning system may, thus, emit a single laser beam which may be configured for the illumination of a single dot located at the surface of the object. By using at least one of the detectors according to the present invention at least one item of information about the distance between the at least one dot and the scanning system may, thus, be generated. Hereby, preferably, the distance between the illumination system as comprised by the scanning system and the single dot as generated by the illumination source may be determined, such as by employing the evaluation device as comprised by the at least one detector. However, the scanning system may, further, comprise an additional evaluation system which may, particularly, be adapted for this purpose. Alternatively or in addition, a size of the scanning system, in particular of the housing of the scanning system, may be taken into account and, thus, the distance between a specific point on the housing of the scanning system, such as a front edge or a back edge of the housing, and the single dot may, alternatively, be determined. The illumination source may be adapted to generate and/or to project a cloud of points, for example the illumination source may comprise one or more of at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources.

Alternatively, the illumination source of the scanning system may emit two individual laser beams which may be configured for providing a respective angle, such as a right angle, between the directions of an emission of the beams, whereby two respective dots located at the surface of the same object or at two different surfaces at two separate objects may be illuminated. However, other values for the respective angle between the two individual laser beams may also be feasible. This feature may, in particular, be employed for indirect measuring functions, such as for deriving an indirect distance which may not be directly accessible, such as due to a presence of one or more obstacles between the scanning system and the dot or which may otherwise be hard to reach. By way of example, it may, thus, be feasible to determine a value for a height of an object by measuring two individual distances and deriving the height by using the Pythagoras formula. In particular for being able to keep a predefined level with respect to the object, the scanning system may, further, comprise at least one leveling unit, in particular an integrated bubble vial, which may be used for keeping the predefined level by the user.

As a further alternative, the illumination source of the scanning system may emit a plurality of individual laser beams, such as an array of laser beams which may exhibit a respective pitch, in particular a regular pitch, with respect to each other and which may be arranged in a manner in order to generate an array of dots located on the at least one surface of the at least one object.

- 5 For this purpose, specially adapted optical elements, such as beam-splitting devices and mirrors, may be provided which may allow a generation of the described array of the laser beams. In particular, the illumination source may be directed to scan an area or a volume by using one or more movable mirrors to redirect the light beam in a periodic or non-periodic fashion.
- 10 Thus, the scanning system may provide a static arrangement of the one or more dots placed on the one or more surfaces of the one or more objects. Alternatively, the illumination source of the scanning system, in particular the one or more laser beams, such as the above described array of the laser beams, may be configured for providing one or more light beams which may exhibit a varying intensity over time and/or which may be subject to an alternating direction of emission
- 15 in a passage of time, in particular by moving one or more mirrors, such as the micro-mirrors comprised within the mentioned array of micro-mirrors. As a result, the illumination source may be configured for scanning a part of the at least one surface of the at least one object as an image by using one or more light beams with alternating features as generated by the at least one illumination source of the scanning device. In particular, the scanning system may, thus, use at
- 20 least one row scan and/or line scan, such as to scan the one or more surfaces of the one or more objects sequentially or simultaneously. Thus, the scanning system may be adapted to measure angles by measuring three or more dots, or the scanning system may be adapted to measure corners or narrow regions such as a gable of a roof, which may be hardly accessible using a conventional measuring stick. As non-limiting examples, the scanning system may be
- 25 used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a
- 30 scanning step. As non-limiting examples, the scanning system may be used in industrial safety curtain applications. As non-limiting examples, the scanning system may be used to perform sweeping, vacuuming, mopping, or waxing functions, or yard or garden care functions such as mowing or raking. As non-limiting examples, the scanning system may employ an LED illumination source with collimated optics and may be adapted to shift the frequency of the illumination
- 35 source to a different frequency to obtain more accurate results and/or employ a filter to attenuate certain frequencies while transmitting others. As non-limiting examples, the scanning system and/or the illumination source may be rotated as a whole or rotating only a particular optics package such as a mirror, beam splitter or the like, using a dedicated motor as such that in operation, the scanning system may have a full 360 degree view or even be moved and or rotated
- 40 out of plane to further increase the scanned area. Further, the illumination source may be actively aimed in a predetermined direction. Further, to allow the rotation of wired electrical systems, slip rings, optical data transmission, or inductive couplings may be employed.

As a non-limiting example, the scanning system may be attached to a tripod and point towards an object or region with a several corners and surfaces. One or more flexibly movable laser sources are attached to the scanning system. The one or more laser sources are moved as such that they illuminate points of interest. The position of the illuminated points with respect to the scanning system is measured when pressing a designated button on the scanning system and the position information is transmitted via a wireless interface to a mobile phone. The position information is stored in a mobile phone application. The laser sources are moved to illuminate further points of interest the position of which are measured and transmitted to the mobile phone application. The mobile phone application may transform the set of points into a 3d model by connecting adjacent points with planar surfaces. The 3d model may be stored and processed further. The distances and or angles between the measured points or surfaces may be displayed directly on a display attached to a scanning system or on the mobile phone to which the position information is transmitted.

As a non-limiting example, a scanning system may comprise two or more flexible movable laser sources to project points and further one movable laser source projecting a line. The line may be used to arrange the two or more laser spots along a line and the display of the scanning device may display the distance between the two or more laser spots that may be arranged along the line, such as at equal distance. In the case of two laser spots, a single laser source may be used whereas the distance of the projected points is modified using one or more beam-splitters or prisms, where a beam-splitter or prism can be moved as such that the projected laser spots move apart or closer together. Further, the scanning system may be adapted to project further patterns such as a right angle, a circle, a square, a triangle, or the like, along which a measurement can be done by projecting laser spots and measuring their position.

As a non-limiting example, the scanning system may be adapted as a line scanning device. In particular, the scanning device may comprise at least one sensor line or row. Triangulation systems require a sufficient baseline such that in the near field no detection may be possible. Near field detection may be possible if the laser spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. These near field and far field problems can be overcome by using the detector according to the present invention. In particular, the detector may comprise a CMOS line of optical sensors. The scanning system may be adapted to detect a plurality of light beams propagating from the object to the detector on the CMOS line. The light beams may be generated at different positions on the object or by movement of the illumination source. The scanning system may be adapted to determine at least one longitudinal coordinate for each of the light points by determining the quotient signal Q as described above and in more detail below.

As a non-limiting example, the scanning system may be adapted to support the work with tools, such as wood or metal processing tools, such as a saw, a driller, or the like. Thus, the scanning system may be adapted to measure the distance in two opposite directions and display the two measured distances or the sum of the distances in a display. Further, the scanning system may be adapted to measure the distance to the edge of a surface as such that when the scanning

system is placed on the surface, a laser point is moved automatically away from the scanning system along the surface, until the distance measurement shows a sudden change due to a corner or the edge of a surface. This makes it possible to measure the distance of the end of a wood plank while the scanning device is placed on the plank but remote from its end. Further, the scanning system may measure the distance of the end of a plank in one direction and project a line or circle or point in a designated distance in the opposite direction. The scanning system may be adapted to project the line or circle or point in a distance depending on the distance measured in the opposite direction such as depending on a predetermined sum distance. This allows working with a tool such as a saw or drill at the projected position while placing the scanning system in a safe distance from the tool and simultaneously perform a process using the tool in a predetermined distance to the edge of the plank. Further, the scanning system may be adapted to project points or lines or the like in two opposite directions in a predetermined distance. When the sum of the distances is changed, only one of the projected distances changes.

As a non-limiting example, the scanning system may be adapted to be placed onto a surface, such as a surface on which a task is performed, such as cutting, sawing, drilling, or the like, and to project a line onto the surface in a predetermined distance that can be adjusted such as with buttons on the scanning device.

As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step.

The transfer device can, as explained above, be designed to feed light propagating from the object to the detector to the optical sensor, preferably successively. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the optical sensor. The transfer device can also be wholly or partly a constituent part of at least one optional illumination source, for example by the illumination source being designed to provide a light beam having defined optical properties, for example having a defined or precisely known beam profile, for example at least one linear combination of Gaussian beams, in particular at least one laser beam having a known beam profile.

The beacon devices and/or the at least one optional illumination source generally may emit light in at least one of: the ultraviolet spectral range, preferably in the range of 200 nm to 380 nm; the visible spectral range (380 nm to 780 nm); the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers, more preferably in the part of the near infrared region where silicon

photodiodes are applicable specifically in the range of 700 nm to 1000 nm. For thermal imaging applications the target may emit light in the far infrared spectral range, preferably in the range of 3.0 micrometers to 20 micrometers. For example, the at least one illumination source is adapted to emit light in the visible spectral range, preferably in the range of 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm. For example, the at least one illumination source is adapted to emit light in the infrared spectral range. Other options, however, are feasible.

The feeding of the light beam to the optical sensor can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is produced on the optional sensor area of the optical sensor. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects can be detected. Preferably, the transfer device may be designed in such a way that the light spot, for example in the case of an object arranged within a visual range of the detector, is arranged completely on a sensor region and/or on a sensor area of the optical sensor. By way of example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

In a further aspect, the present invention discloses an inertial measurement unit for use in an electronic device. The electronic device may be a mobile electronic device. The electronic device may be a camera. The electronic device may be a mobile phone. The inertial measurement unit is adapted to receive data determined by at least one inertial measurement unit comprising at least one detector according to the present invention, such as according to one or more of the embodiments referring to a detector as disclosed above or as disclosed in further detail below. As used herein, the term "data determined by the at least one detector" refers to at least one information on the at least one longitudinal coordinate z . The inertial measurement unit further is adapted to receive data determined by at least one further sensor selected from the group consisting of: a wheel speed sensor, a turn rate sensor, an inclination sensor, an orientation sensor, a motion sensor, a magneto hydro dynamic sensor, a force sensor, an angular sensor, an angular rate sensor, a magnetic field sensor, a magnetometer, an accelerometer; a gyroscope. As used herein, the term "data determined by the at least one further sensor" refers to at least one information selected from the group consisting of: angle information; speed information; information on turn rate; information on inclination. The inertial measurement unit is adapted to determine by evaluating the data from the detector and the at least one further sensor at least one property of the electronic device selected from the group consisting of: position in space, relative or absolute motion in space, rotation, acceleration, orientation, angle position, inclination, turn rate, speed. The inertial measurement unit may comprise at least one processor. The processor may be adapted to evaluate data recorded by the further sensor. In particular, the processor may be adapted to determine and/or calculate one or more of spatial position, spatial orientation, movement and velocity. The inertial measurement unit may comprise a plurality of further sensors. The inertial measurement unit may be adapted to fuse information determined from at least two of the further sensors. The inertial measurement unit may be adapted to fuse information of at least two further sensors by using at least one Kalman filter. As outlined

above, the detector may be adapted to provide an absolute measurement of the longitudinal coordinate z . The processor, e.g. the evaluation device as described above, may be adapted to fuse the information of the at least two further sensors considering the longitudinal coordinate z . The various sensor signals may be used within a Kalman filter or a linear quadratic estimated to take into account that each sensor signal is subject to measurement errors and inaccuracies. Fusion of these sensor signals within a Kalman filter may yield an improved estimate such as for the measurement of the longitudinal coordinate.

In a further aspect, the present invention discloses a method for determining a position of at least one object by using a detector, such as a detector according to the present invention, such as according to one or more of the embodiments referring to a detector as disclosed above or as disclosed in further detail below. Still, other types of detectors may be used. The method comprises the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed. Further, one, more than one or even all of the method steps may be performed repeatedly.

The method comprises the following method steps:

- providing at least two optical sensors, each optical sensor having a light-sensitive area, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by the light beam, wherein the detector has at least one transfer device, wherein the transfer device has at least one focal length in response to the light beam propagating from the object to the detector;
- illuminating each of light-sensitive areas of at least two optical sensors of the detector with a light beam propagating from the object to the detector, wherein, thereby, each of the light-sensitive areas generates at least one sensor signal; and
- evaluating the sensor signals, thereby, determining at least one longitudinal coordinate z of the object, wherein the evaluating comprises deriving a quotient signal Q of the sensor signals.

The longitudinal coordinate z of the object may be determined in at least one measurement range independent from the object size in an object plane.

The deriving of the quotient signal Q may comprise one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

The method may comprise adjusting the measurement range by adjusting on one or more parameters selected from the group consisting of: a longitudinal distance from the object to the transfer device z_0 ; the focal length of the transfer device f ; a diameter of an exit pupil of the transfer device E_x ; a longitudinal distance from the transfer device to the light sensitive area z_s , a distance from the transfer device to an image of the object z_i ; an object size O_{size} of the object in the object plane.

The transfer device may have an optical axis. With respect to embodiments of the transfer device reference is made to the embodiments of the transfer device described with respect to a first aspect above.

5 For details, options and definitions, reference may be made to the detector as discussed above. Thus, specifically, as outlined above, the method may comprise using the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below.

10 In a first preferred embodiment the method may comprise the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed. Further, one, more than one or even all of the method steps may be performed repeatedly.

15 The method steps may be as follows:

- illuminating at least one first light-sensitive area of at least one first optical sensor of the detector with a light beam propagating from the object to the detector and, thereby, generating at least one first sensor signal;
- illuminating at least one second light-sensitive area of at least one second optical
20 sensor of the detector with the light beam and, thereby, generating at least one second sensor signal, wherein the first light-sensitive area is smaller than the second light-sensitive area; and
- evaluating the first and second sensor signals, thereby determining at least one longitudinal coordinate z of the object.

25

Specifically, evaluating the first and second sensor signal may comprise deriving the quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals. Further, the determining the longitudinal coordinate may comprise evaluating the quotient signal

30

Q .

In a second preferred embodiment the method may comprise the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed.

35 Further, one, more than one or even all of the method steps may be performed repeatedly.

The method steps may be as follows:

- illuminating at least one sensor element of the detector with at least one light beam propagating from the object to the detector, the detector having a matrix of optical
40 sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor generates at least one sensor signal in response to the illumination;
- evaluating the sensor signals, by

- determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
 - a) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;
 - b) determining at least one combined signal by combining the center signal and the sum signal; and
 - c) determining at least one longitudinal coordinate z of the object by evaluating the combined signal.

Specifically, the evaluation of the first and second sensor signal may comprise deriving the quotient signal Q by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal. Further, the determination of the longitudinal coordinate may comprise evaluating the quotient signal Q . The evaluation of the quotient signal specifically may comprise using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate, in order to determine the longitudinal coordinate.

In a third preferred embodiment the method may comprise the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed. Further, one, more than one or even all of the method steps may be performed repeatedly.

The method steps may be as follows:

- providing at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different separations, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by a light;
- illuminating the at least two light-sensitive areas of the at least two optical sensors of the detector with a light beam propagating from the object to the detector and, thereby, generating at least two sensor signals; and
- evaluating the sensor signals by combining the at least two sensor signals, thereby determining at least one longitudinal coordinate z of the object.

Specifically, evaluating the first and second sensor signal may comprise deriving the quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals, and wherein the determining of the longitudinal coordinate comprises evaluating the quotient signal Q . Further, the determining of the longitudinal coordinate may comprise evaluating the quotient signal Q .

In a further preferred embodiment the method may comprise the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed. Further, one, more than one or even all of the method steps may be performed repeatedly.

The method steps may be as follows:

- illuminating at least one first light-sensitive area of at least one first optical sensor with a light beam propagating from the object to the detector and generating at least one first sensor signal by the first optical sensor, in response to the illumination of the first light-sensitive area;
 - illuminating at least one second light-sensitive area of at least one second optical sensor with the light beam and generating at least one second sensor signal by the second optical sensor, in response to the illumination of the second light-sensitive area, the second optical sensor having:
 - o at least one fluorescent waveguiding sheet forming a second light-sensitive area, wherein the fluorescent waveguiding sheet is oriented towards the object such that at least one light beam propagating from the object towards the detector generates at least one light spot in the second light-sensitive area, wherein the fluorescent waveguiding sheet contains at least one fluorescent material, wherein the fluorescent material is adapted to generate fluorescence light in response to the illumination by the light beam; and
 - o at least one photosensitive element located at at least one edge of the fluorescent waveguiding sheet, capable of detecting fluorescence light guided from the light spot towards the photosensitive element by the fluorescent waveguiding sheet and capable of generating the at least one second sensor signal in response to the illumination of the second light-sensitive area by the light beam, wherein the first light-sensitive area is smaller than the second light-sensitive area; and
 - determining at least one longitudinal coordinate z of the object by evaluating the first and second sensor signals.
- Specifically, as discussed above, the evaluating the first and second sensor signals may comprise deriving a quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals. The determining the at least one longitudinal coordinate of the object may comprise evaluating the quotient signal Q . as discussed above, at least one predetermined relationship between the quotient signal and the longitudinal coordinate may be used for determining the longitudinal coordinate.

As also discussed above, the second optical sensor specifically may comprise at least two photosensitive elements. The method may further comprise determining at least one transversal coordinate x , y of the object by evaluating the sensor signals of the photosensitive elements.

For details, options and definitions, reference may be made to the detector as discussed above. Thus, specifically, as outlined above, the method may comprise using the detector according to

the present invention, such as according to one or more of the embodiments given above or given in further detail below.

In a further preferred embodiment, the method comprises the following steps:

- 5 - providing at least one angle dependent optical element and generating at least one light beam having at least one beam profile depending on an angle of incidence;
- providing at least two optical sensors, wherein each optical sensor has at least one light sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by the light
- 10 beam generated by the angle dependent optical element;
- illuminating each of the light-sensitive areas of the at least two optical sensors of the detector with the light beam generated by the angle dependent optical element, wherein, thereby, each of the light-sensitive areas generates at least one sensor signal; and
- 15 evaluating the sensor signals, thereby, determining at least one longitudinal coordinate z of the object, wherein the evaluating comprises deriving the quotient signal Q of the sensor signals.

Specifically, evaluating the first and second sensor signal may comprise deriving the quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals.

20 Further, the determining the longitudinal coordinate may comprise evaluating the quotient signal Q .

As also discussed above, the second optical sensor specifically may comprise at least two photosensitive elements. The method may further comprise determining at least one transversal

25 coordinate x , y of the object by evaluating the sensor signals of the photosensitive elements.

For details, options and definitions, reference may be made to the detector as discussed above. Thus, specifically, as outlined above, the method may comprise using the detector according to the present invention, such as according to one or more of the embodiments given above or

30 given in further detail below.

In a further aspect of the present invention, use of the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below, is proposed, for a purpose of use, selected from the group consisting of: a position

35 measurement in traffic technology; an entertainment application; an optical data storage application; a security application; a surveillance application; a safety application; a human-machine interface application; a tracking application; a photography application; an imaging application or camera application; a mapping application for generating maps of at least one space; a homing or tracking beacon detector for vehicles; a machine vision application; a robotics application;

40 a quality control application; a manufacturing application.

The object generally may be a living or non-living object. The detector or the detector system even may comprise the at least one object, the object thereby forming part of the detector sys-

tem. Preferably, however, the object may move independently from the detector, in at least one spatial dimension. The object generally may be an arbitrary object. In one embodiment, the object may be a rigid object. Other embodiments are feasible, such as embodiments in which the object is a non-rigid object or an object which may change its shape.

5

As will be outlined in further detail below, the present invention may specifically be used for tracking positions and/or motions of a person, such as for the purpose of controlling machines, gaming or simulation of sports. In this or other embodiments, specifically, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat; an article of clothing; a hat; a shoe.

10

Thus, generally, the devices according to the present invention, such as the detector, may be applied in various fields of uses. Specifically, the detector may be applied for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a human-machine interface application; a tracking application; a photography application; a mapping application for generating maps of at least one space, such as at least one space selected from the group of a room, a building and a street; a mobile application; a webcam; an audio device; a dolby surround audio system; a computer peripheral device; a gaming application; a camera or video application; a security application; a surveillance application; an automotive application; a transport application; a medical application; a sports' application; a machine vision application; a vehicle application; an airplane application; a ship application; a spacecraft application; a building application; a construction application; a cartography application; a manufacturing application. Additionally or alternatively, applications in local and/or global positioning systems may be named, especially landmark-based positioning and/or navigation, specifically for use in cars or other vehicles (such as trains, motorcycles, bicycles, trucks for cargo transportation), robots or for use by pedestrians. Further, indoor positioning systems may be named as potential applications, such as for household applications and/or for robots used in manufacturing, logistics, surveillance, or maintenance technology.

15

20

25

30

The devices according to the present invention may be used in mobile phones, tablet computers, laptops, smart panels or other stationary or mobile or wearable computer or communication applications. Thus, the devices according to the present invention may be combined with at least one active light source, such as a light source emitting light in the visible range or infrared spectral range, in order to enhance performance. Thus, as an example, the devices according to the present invention may be used as cameras and/or sensors, such as in combination with mobile software for scanning and/or detecting environment, objects and living beings. The devices according to the present invention may even be combined with 2D cameras, such as conventional cameras, in order to increase imaging effects. The devices according to the present invention may further be used for surveillance and/or for recording purposes or as input devices to control mobile devices, especially in combination with voice and/or gesture recognition. Thus, specifically, the devices according to the present invention acting as human-machine interfaces, also referred to as input devices, may be used in mobile applications, such as for controlling

35

40

other electronic devices or components via the mobile device, such as the mobile phone. As an example, the mobile application including at least one device according to the present invention may be used for controlling a television set, a game console, a music player or music device or other entertainment devices.

5

Further, the devices according to the present invention may be used in webcams or other peripheral devices for computing applications. Thus, as an example, the devices according to the present invention may be used in combination with software for imaging, recording, surveillance, scanning or motion detection. As outlined in the context of the human-machine interface and/or the entertainment device, the devices according to the present invention are particularly useful for giving commands by facial expressions and/or body expressions. The devices according to the present invention can be combined with other input generating devices like e.g. mouse, keyboard, touchpad, microphone etc. Further, the devices according to the present invention may be used in applications for gaming, such as by using a webcam. Further, the devices according to the present invention may be used in virtual training applications and/or video conferences. Further, devices according to the present invention may be used to recognize or track hands, arms, or objects used in a virtual or augmented reality application, especially when wearing head-mounted displays.

10

15

20

25

Further, the devices according to the present invention may be used in mobile audio devices, television devices and gaming devices, as partially explained above. Specifically, the devices according to the present invention may be used as controls or control devices for electronic devices, entertainment devices or the like. Further, the devices according to the present invention may be used for eye detection or eye tracking, such as in 2D- and 3D-display techniques, especially with transparent displays for augmented reality applications and/or for recognizing whether a display is being looked at and/or from which perspective a display is being looked at. Further, devices according to the present invention may be used to explore a room, boundaries, obstacles, in connection with a virtual or augmented reality application, especially when wearing a head-mounted display.

30

Further, the devices according to the present invention may be used in or as digital cameras such as DSC cameras and/or in or as reflex cameras such as SLR cameras. For these applications, reference may be made to the use of the devices according to the present invention in mobile applications such as mobile phones, as disclosed above.

35

Further, the devices according to the present invention may be used for security or surveillance applications. Thus, as an example, at least one device according to the present invention can be combined with one or more digital and/or analogue electronics that will give a signal if an object is within or outside a predetermined area (e.g. for surveillance applications in banks or museums). Specifically, the devices according to the present invention may be used for optical encryption. Detection by using at least one device according to the present invention can be combined with other detection devices to complement wavelengths, such as with IR, x-ray, UV-VIS, radar or ultrasound detectors. The devices according to the present invention may further

40

be combined with an active infrared light source to allow detection in low light surroundings. The devices according to the present invention are generally advantageous as compared to active detector systems, specifically since the devices according to the present invention avoid actively sending signals which may be detected by third parties, as is the case e.g. in radar applications, ultrasound applications, LIDAR or similar active detector devices. Thus, generally, the devices according to the present invention may be used for an unrecognized and undetectable tracking of moving objects. Additionally, the devices according to the present invention generally are less prone to manipulations and irritations as compared to conventional devices.

Further, given the ease and accuracy of 3D detection by using the devices according to the present invention, the devices according to the present invention generally may be used for facial, body and person recognition and identification. Therein, the devices according to the present invention may be combined with other detection means for identification or personalization purposes such as passwords, finger prints, iris detection, voice recognition or other means. Thus, generally, the devices according to the present invention may be used in security devices and other personalized applications.

Further, the devices according to the present invention may be used as 3D barcode readers for product identification.

In addition to the security and surveillance applications mentioned above, the devices according to the present invention generally can be used for surveillance and monitoring of spaces and areas. Thus, the devices according to the present invention may be used for surveying and monitoring spaces and areas and, as an example, for triggering or executing alarms in case prohibited areas are violated. Thus, generally, the devices according to the present invention may be used for surveillance purposes in building surveillance or museums, optionally in combination with other types of sensors, such as in combination with motion or heat sensors, in combination with image intensifiers or image enhancement devices and/or photomultipliers. Further, the devices according to the present invention may be used in public spaces or crowded spaces to detect potentially hazardous activities such as commitment of crimes such as theft in a parking lot or unattended objects such as unattended baggage in an airport.

Further, the devices according to the present invention may advantageously be applied in camera applications such as video and camcorder applications. Thus, the devices according to the present invention may be used for motion capture and 3D-movie recording. Therein, the devices according to the present invention generally provide a large number of advantages over conventional optical devices. Thus, the devices according to the present invention generally require a lower complexity with regard to optical components. Thus, as an example, the number of lenses may be reduced as compared to conventional optical devices, such as by providing the devices according to the present invention having one lens only. Due to the reduced complexity, very compact devices are possible, such as for mobile use. Conventional optical systems having two or more lenses with high quality generally are voluminous, such as due to the general need for voluminous beam-splitters. Further, the devices according to the present invention

generally may be used for focus/autofocus devices, such as autofocus cameras. Further, the devices according to the present invention may also be used in optical microscopy, especially in confocal microscopy.

- 5 Further, the devices according to the present invention generally are applicable in the technical field of automotive technology and transport technology. Thus, as an example, the devices according to the present invention may be used as distance and surveillance sensors, such as for adaptive cruise control, emergency brake assist, lane departure warning, surround view, blind spot detection, traffic sign detection, traffic sign recognition, lane recognition, rear cross traffic alert, light source recognition for adapting the head light intensity and range depending on approaching traffic or vehicles driving ahead, adaptive frontlighting systems, automatic control of high beam head lights, adaptive cut-off lights in front light systems, glare-free high beam front lighting systems, marking animals, obstacles, or the like by headlight illumination, rear cross traffic alert, and other driver assistance systems such as advanced driver assistance systems, or other automotive and traffic applications. Further, devices according to the present invention may be used in driver assistance systems anticipating maneuvers of the driver beforehand for collision avoidance or the like. Further, the devices according to the present invention can also be used for velocity and/or acceleration measurements, such as by analyzing a first and second time-derivative of position information gained by using the detector according to the present invention. This feature generally may be applicable in automotive technology, transportation technology or general traffic technology. Applications in other fields of technology are feasible. A specific application in an indoor positioning system may be the detection of positioning of passengers in transportation, more specifically to electronically control the use of safety systems such as airbags. The use of an airbag may be prevented in case the passenger is located as such, that the use of an airbag will cause a severe injury. Further, in vehicles such as cars, trains, planes or the like, especially in autonomous vehicles, devices according to the present invention may be used to determine whether a driver pays attention to the traffic or is distracted, or asleep, or tired, or incapable of driving such as due to the consumption of alcohol or the like.
- 30 In these or other applications, generally, the devices according to the present invention may be used as standalone devices or in combination with other sensor devices, such as in combination with radar and/or ultrasonic devices. Specifically, the devices according to the present invention may be used for autonomous driving and safety issues. Further, in these applications, the devices according to the present invention may be used in combination with infrared sensors, radar sensors, which are sonic sensors, two-dimensional cameras or other types of sensors. In these applications, the generally passive nature of the devices according to the present invention is advantageous. Thus, since the devices according to the present invention generally do not require emitting signals, the risk of interference of active sensor signals with other signal sources may be avoided. The devices according to the present invention specifically may be used in combination with recognition software, such as standard image recognition software. Thus, signals and data as provided by the devices according to the present invention typically are readily processable and, therefore, generally require lower calculation power than established 3D measurement systems. Given the low space demand, the devices according to the

present invention such as cameras may be placed at virtually any place in a vehicle, such as on or behind a window screen, on a front hood, on bumpers, on lights, on mirrors or other places and the like. Various detectors according to the present invention such as one or more detectors based on the effect disclosed within the present invention can be combined, such as in order to allow autonomously driving vehicles or in order to increase the performance of active safety concepts. Thus, various devices according to the present invention may be combined with one or more other devices according to the present invention and/or conventional sensors, such as in the windows like rear window, side window or front window, on the bumpers or on the lights.

A combination of at least one device according to the present invention such as at least one detector according to the present invention with one or more rain detection sensors is also possible. This is due to the fact that the devices according to the present invention generally are advantageous over conventional sensor techniques such as radar, specifically during heavy rain. A combination of at least one device according to the present invention with at least one conventional sensing technique such as radar may allow for a software to pick the right combination of signals according to the weather conditions.

Further, the devices according to the present invention generally may be used as break assist and/or parking assist and/or for speed measurements. Speed measurements can be integrated in the vehicle or may be used outside the vehicle, such as in order to measure the speed of other cars in traffic control. Further, the devices according to the present invention may be used for detecting free parking spaces in parking lots.

Further, the devices according to the present invention may be used in the fields of medical systems and sports. Thus, in the field of medical technology, surgery robotics, e.g. for use in endoscopes, may be named, since, as outlined above, the devices according to the present invention may require a low volume only and may be integrated into other devices. Specifically, the devices according to the present invention having one lens, at most, may be used for capturing 3D information in medical devices such as in endoscopes. Further, the devices according to the present invention may be combined with an appropriate monitoring software, in order to enable tracking and analysis of movements. This may allow an instant overlay of the position of a medical device, such as an endoscope or a scalpel, with results from medical imaging, such as obtained from magnetic resonance imaging, x-ray imaging, or ultrasound imaging. These applications are specifically valuable e.g. in medical treatments where precise location information is important such as in brain surgery and long-distance diagnosis and tele-medicine. Further, the devices according to the present invention may be used in 3D-body scanning. Body scanning may be applied in a medical context, such as in dental surgery, plastic surgery, bariatric surgery, or cosmetic plastic surgery, or it may be applied in the context of medical diagnosis such as in the diagnosis of myofascial pain syndrome, cancer, body dysmorphic disorder, or further diseases. Body scanning may further be applied in the field of sports to assess ergonomic use or fit of sports equipment. Further, the devices according to the present invention may be used in wearable robots such as in exoskeletons or prosthesis or the like.

Body scanning may further be used in the context of clothing, such as to determine a suitable size and fitting of clothes. This technology may be used in the context of tailor-made clothes or in the context of ordering clothes or shoes from the internet or at a self-service shopping device such as a micro kiosk device or customer concierge device. Body scanning in the context of clothing is especially important for scanning fully dressed customers.

Further, the devices according to the present invention may be used in the context of people counting systems, such as to count the number of people in an elevator, a train, a bus, a car, or a plane, or to count the number of people passing a hallway, a door, an aisle, a retail store, a stadium, an entertainment venue, a museum, a library, a public location, a cinema, a theater, or the like. Further, the 3D-function in the people counting system may be used to obtain or estimate further information about the people that are counted such as height, weight, age, physical fitness, or the like. This information may be used for business intelligence metrics, and/or for further optimizing the locality where people may be counted to make it more attractive or safe.

In a retail environment, the devices according to the present invention in the context of people counting may be used to recognize returning customers or cross shoppers, to assess shopping behavior, to assess the percentage of visitors that make purchases, to optimize staff shifts, or to monitor the costs of a shopping mall per visitor. Further, people counting systems may be used for anthropometric surveys. Further, the devices according to the present invention may be used in public transportation systems for automatically charging passengers depending on the length of transport. Further, the devices according to the present invention may be used in playgrounds for children, to recognize injured children or children engaged in dangerous activities, to allow additional interaction with playground toys, to ensure safe use of playground toys or the like.

Further the devices according to the present invention may be used in construction tools, such as a range meter that determines the distance to an object or to a wall, to assess whether a surface is planar, to align objects or place objects in an ordered manner, or in inspection cameras for use in construction environments or the like.

Further, the devices according to the present invention may be applied in the field of sports and exercising, such as for training, remote instructions or competition purposes. Specifically, the devices according to the present invention may be applied in the fields of dancing, aerobic, football, soccer, basketball, baseball, cricket, hockey, track and field, swimming, polo, handball, volleyball, rugby, sumo, judo, fencing, boxing, golf, car racing, laser tag, battlefield simulation etc. The devices according to the present invention can be used to detect the position of a ball, a bat, a sword, motions, etc., both in sports and in games, such as to monitor the game, support the referee or for judgment, specifically automatic judgment, of specific situations in sports, such as for judging whether a point or a goal actually was made.

Further, the devices according to the present invention may be used in the field of auto racing or car driver training or car safety training or the like to determine the position of a car or the track of a car, or the deviation from a previous track or an ideal track or the like.

The devices according to the present invention may further be used to support a practice of musical instruments, in particular remote lessons, for example lessons of string instruments, such as fiddles, violins, violas, celli, basses, harps, guitars, banjos, or ukuleles, keyboard instruments, such as pianos, organs, keyboards, harpsichords, harmoniums, or accordions, and/or percussion instruments, such as drums, timpani, marimbas, xylophones, vibraphones, bongos, congas, timbales, djembes or tablas.

The devices according to the present invention further may be used in rehabilitation and physiotherapy, in order to encourage training and/or in order to survey and correct movements. Therein, the devices according to the present invention may also be applied for distance diagnostics.

Further, the devices according to the present invention may be applied in the field of machine vision. Thus, one or more of the devices according to the present invention may be used e.g. as a passive controlling unit for autonomous driving and or working of robots. In combination with moving robots, the devices according to the present invention may allow for autonomous movement and/or autonomous detection of failures in parts. The devices according to the present invention may also be used for manufacturing and safety surveillance, such as in order to avoid accidents including but not limited to collisions between robots, production parts and living beings. In robotics, the safe and direct interaction of humans and robots is often an issue, as robots may severely injure humans when they are not recognized. Devices according to the present invention may help robots to position objects and humans better and faster and allow a safe interaction. Given the passive nature of the devices according to the present invention, the devices according to the present invention may be advantageous over active devices and/or may be used complementary to existing solutions like radar, ultrasound, 2D cameras, IR detection etc. One particular advantage of the devices according to the present invention is the low likelihood of signal interference. Therefore multiple sensors can work at the same time in the same environment, without the risk of signal interference. Thus, the devices according to the present invention generally may be useful in highly automated production environments like e.g. but not limited to automotive, mining, steel, etc. The devices according to the present invention can also be used for quality control in production, e.g. in combination with other sensors like 2-D imaging, radar, ultrasound, IR etc., such as for quality control or other purposes. Further, the devices according to the present invention may be used for assessment of surface quality, such as for surveying the surface evenness of a product or the adherence to specified dimensions, from the range of micrometers to the range of meters. Other quality control applications are feasible. In a manufacturing environment, the devices according to the present invention are especially useful for processing natural products such as food or wood, with a complex 3-dimensional structure to avoid large amounts of waste material. Further, devices according to the present invention may be used to monitor the filling level of tanks, silos etc. Further, devices according to the present invention may be used to inspect complex products for missing parts, incomplete parts, loose parts, low quality parts, or the like, such as in automatic optical inspection, such as of printed circuit boards, inspection of assemblies or sub-assemblies, verification of engineered components, engine part inspections, wood quality inspection, label inspections,

inspection of medical devices, inspection of product orientations, packaging inspections, food pack inspections, or the like.

Further, the devices according to the present invention may be used in vehicles, trains, air-
5 planes, ships, spacecraft and other traffic applications. Thus, besides the applications mentioned above in the context of traffic applications, passive tracking systems for aircraft, vehicles and the like may be named. The use of at least one device according to the present invention, such as at least one detector according to the present invention, for monitoring the speed
10 and/or the direction of moving objects is feasible. Specifically, the tracking of fast moving objects on land, sea and in the air including space may be named. The at least one device according to the present invention, such as the at least one detector according to the present invention, specifically may be mounted on a still-standing and/or on a moving device. An output signal of the at least one device according to the present invention can be combined e.g. with a
15 guiding mechanism for autonomous or guided movement of another object. Thus, applications for avoiding collisions or for enabling collisions between the tracked and the steered object are feasible. The devices according to the present invention generally are useful and advantageous due to the low calculation power required, the instant response and due to the passive nature of the detection system which generally is more difficult to detect and to disturb as compared to
20 active systems, like e.g. radar. The devices according to the present invention are particularly useful but not limited to e.g. speed control and air traffic control devices. Further, the devices according to the present invention may be used in automated tolling systems for road charges.

The devices according to the present invention generally may be used in passive applications. Passive applications include guidance for ships in harbors or in dangerous areas, and for air-
25 craft when landing or starting. Wherein, fixed, known active targets may be used for precise guidance. The same can be used for vehicles driving on dangerous but well defined routes, such as mining vehicles. Further, the devices according to the present invention may be used to detect rapidly approaching objects, such as cars, trains, flying objects, animals, or the like. Further, the devices according to the present invention can be used for detecting velocities or ac-
30 celerations of objects, or to predict the movement of an object by tracking one or more of its position, speed, and/or acceleration depending on time.

Further, as outlined above, the devices according to the present invention may be used in the field of gaming. Thus, the devices according to the present invention can be passive for use
35 with multiple objects of the same or of different size, color, shape, etc., such as for movement detection in combination with software that incorporates the movement into its content. In particular, applications are feasible in implementing movements into graphical output. Further, applications of the devices according to the present invention for giving commands are feasible, such as by using one or more of the devices according to the present invention for gesture or
40 facial recognition. The devices according to the present invention may be combined with an active system in order to work under e.g. low light conditions or in other situations in which enhancement of the surrounding conditions is required. Additionally or alternatively, a combination of one or more devices according to the present invention with one or more IR or VIS light

sources is possible. A combination of a detector according to the present invention with special devices is also possible, which can be distinguished easily by the system and its software, e.g. and not limited to, a special color, shape, relative position to other devices, speed of movement, light, frequency used to modulate light sources on the device, surface properties, material used, reflection properties, transparency degree, absorption characteristics, etc. The device can, amongst other possibilities, resemble a stick, a racket, a club, a gun, a knife, a wheel, a ring, a steering wheel, a bottle, a ball, a glass, a vase, a spoon, a fork, a cube, a dice, a figure, a puppet, a teddy, a beaker, a pedal, a switch, a glove, jewelry, a musical instrument or an auxiliary device for playing a musical instrument, such as a plectrum, a drumstick or the like. Other options are feasible.

Further, the devices according to the present invention may be used to detect and or track objects that emit light by themselves, such as due to high temperature or further light emission processes. The light emitting part may be an exhaust stream or the like. Further, the devices according to the present invention may be used to track reflecting objects and analyze the rotation or orientation of these objects.

Further, the devices according to the present invention generally may be used in the field of building, construction and cartography. Thus, generally, one or more devices according to the present invention may be used in order to measure and/or monitor environmental areas, e.g. countryside or buildings. Therein, one or more devices according to the present invention may be combined with other methods and devices or can be used solely in order to monitor progress and accuracy of building projects, changing objects, houses, etc. The devices according to the present invention can be used for generating three-dimensional models of scanned environments, in order to construct maps of rooms, streets, houses, communities or landscapes, both from ground or from air. Potential fields of application may be construction, cartography, real estate management, land surveying or the like. As an example, the devices according to the present invention may be used in drones or multicopters to monitor buildings, production sites, chimneys, agricultural production environments such as fields, production plants, or landscapes, to support rescue operations, to support work in dangerous environments, to support fire brigades in a burning location indoors or outdoors, or to find or monitor one or more persons or animals, or the like, or for entertainment purposes, such as a drone following and recording one or more persons doing sports such as skiing or cycling or the like, which could be realized by following a helmet, a mark, a beacon device, or the like. Devices according to the present invention could be used recognize obstacles, follow a predefined route, follow an edge, a pipe, a building, or the like, or to record a global or local map of the environment. Further, devices according to the present invention could be used for indoor or outdoor localization and positioning of drones, for stabilizing the height of a drone indoors where barometric pressure sensors are not accurate enough, or for the interaction of multiple drones such as concertized movements of several drones or recharging or refueling in the air or the like.

Further, the devices according to the present invention may be used within an interconnecting network of home appliances such as CHAIN (Cedec Home Appliances Interoperating Network)

to interconnect, automate, and control basic appliance-related services in a home, e.g. energy or load management, remote diagnostics, pet related appliances, child related appliances, child surveillance, appliances related surveillance, support or service to elderly or ill persons, home security and/or surveillance, remote control of appliance operation, and automatic maintenance support. Further, the devices according to the present invention may be used in heating or cooling systems such as an air-conditioning system, to locate which part of the room should be brought to a certain temperature or humidity, especially depending on the location of one or more persons. Further, the devices according to the present invention may be used in domestic robots, such as service or autonomous robots which may be used for household chores. The devices according to the present invention may be used for a number of different purposes, such as to avoid collisions or to map the environment, but also to identify a user, to personalize the robot's performance for a given user, for security purposes, or for gesture or facial recognition. As an example, the devices according to the present invention may be used in robotic vacuum cleaners, floor-washing robots, dry-sweeping robots, ironing robots for ironing clothes, animal litter robots, such as dog or cat litter robots, charging robot for electrical vehicles, security robots that detect intruders, robotic lawn mowers, automated pool cleaners, rain gutter cleaning robots, robotic shopping carts, luggage carrying robots, line following robots, laundry robots, ironing robots, window washing robots, toy robots, , patient monitoring robots, baby monitoring robots, elderly monitoring robots, children monitoring robots, transport robots, telepresence robots, professional service robots, programmable toy robots, pathfinder robots, social robots providing company to less mobile people, following robots, smart card following robots, psychotherapy robots, or robots translating and speech to sign language or sign language to speech. In the context of less mobile people, such as elderly persons, household robots with the devices according to the present invention may be used for picking up objects, transporting objects, and interacting with the objects and the user in a safe way. Further, the devices according to the present invention may be used in humanoid robots, especially in the context of using humanoid hands to pick up or hold or place objects. Further, the devices according to the present invention may be used in combination with audio interfaces especially in combination with household robots which may serve as a digital assistant with interfaces to online or offline computer applications. Further, the devices according to the present invention may be used in robots that can control switches and buttons in industrial and household purposes. Further, the devices according to the present invention may be used in smart home robots such as Mayfield's Kuri. Further the devices according to the present invention may be used in robots operating with hazardous materials or objects or in dangerous environments. As a non-limiting example, the devices according to the present invention may be used in robots or unmanned remote-controlled vehicles to operate with hazardous materials such as chemicals or radioactive materials especially after disasters, or with other hazardous or potentially hazardous objects such as mines, unexploded arms, or the like, or to operate in or to investigate insecure environments such as near burning objects or post disaster areas or for manned or unmanned rescue operations in the air, in the sea, underground, or the like.

Further, devices according to the present invention may be used for the inspection of adhesive beads, sealing beads, or the like, such as to recognize disruptions, slubs, contractions, asy-

metries, local defects, or the like. Further, devices according to the present invention may be used to count objects such as dry fruits on a conveyer belt, such as in difficult situations, such as when fruit of similar color and shape may be in direct contact with each other. Further, devices according to the present invention may be used in quality control of die cast or injection molded parts such as to ensure flawless casting or molding, recognize surface damages, worn out toolings or the like. Further, devices according to the present invention may be used for laserscribing such as for quality control and positioning of the laser. Further, devices according to the present invention may be used for sorting systems, such as to detect position, rotation, and shape of an object, compare it to a database of objects, and classify the object. Further, devices according to the present invention may be used for stamping part inspection, packaging inspection, such as food and pharma packaging inspection, filament inspection, or the like.

Further, devices according to the present invention may be used for navigation purposes, where Global Positioning Systems (GPS) are not sufficiently reliable. GPS signals commonly use radio waves that are can be blocked or difficult to receive indoors or outdoors in valleys or in forests below the treeline. Further, especially in unmanned autonomous vehicles, the weight of the system may be critical. Especially unmanned autonomous vehicles need high-speed position data for reliable feedback and stability of their control systems. Using devices according to the present invention may allow short time response and positioning without adding weight due to a heavy device.

Further, the devices according to the present invention may be used in household, mobile or entertainment devices, such as a refrigerator, a microwave, a washing machine, a window blind or shutter, a household alarm, an air condition devices, a heating device, a television, an audio device, a smart watch, a mobile phone, a phone, a dishwasher, a stove or the like, to detect the presence of a person, to monitor the contents or function of the device, or to interact with the person and/or share information about the person with further household, mobile or entertainment devices.

Further, the devices according to the present invention may be used to support elderly or disabled persons or persons with limited or no vision, such as in household chores or at work such as in devices for holding, carrying, or picking objects, or in a safety system with optical or acoustical signals signaling obstacles in the environment.

The devices according to the present invention may further be used in agriculture, for example to detect and sort out vermin, weeds, and/or infected crop plants, fully or in parts, wherein crop plants may be infected by fungus or insects. Further, for harvesting crops, the devices according to the present invention may be used to detect animals, such as deer, which may otherwise be harmed by harvesting devices. Further, the devices according to the present invention may be used to monitor the growth of plants in a field or greenhouse, in particular to adjust the amount of water or fertilizer or crop protection products for a given region in the field or green-

house or even for a given plant. Further, in agricultural biotechnology, the devices according to the present invention may be used to monitor the size and shape of plants.

Further, devices according to the present invention may be used to automatically remove weeds such as with mechanical means, such as to avoid the use of herbicides. Further, devices according to the present invention may be used in the field of agriculture, in particular to detect and/or locate specific insects such as to decide whether or not to apply a crop protection or fertilization substance, such as to reduce the amount of applied substance or to protect specific groups of animals such as bees.

Further, devices according to the present invention may be used to guide users during a shaving, hair cutting, or cosmetics procedure, or the like. Further, devices according to the present invention may be used to record or monitor what is played on an instrument, such as a violin. Further, devices according to the present invention may be used in smart household appliances such as a smart refrigerator, such as to monitor the contents of the refrigerator and transmit notifications depending on the contents. Further, devices according to the present invention may be used for monitoring or tracking populations of humans, animals, or plants, such as deer or tree populations in forests. Further, devices according to the present invention may be used in harvesting machines, such as for harvesting crops, flowers or fruits, such as grapes, corn, hops, apples, grains, rice, strawberries, asparagus, tulips, roses, soy beans, or the like. Further, devices according to the present invention may be used to monitor the growth of plants, animals, algae, fish, or the like, such as in breeding, food production, agriculture or research applications, to control irrigation, fertilization, humidity, temperature, use of herbicides, insecticides, fungicides, rodenticides, or the like. Further, devices according to the present invention may be used in feeding machines for animals or pets, such as for cows, pigs, cats, dogs, birds, fish, or the like. Further, devices according to the present invention may be used in animal product production processes, such as for collecting milk, eggs, fur, meat, or the like, such as in automated milking or butchering processes. Further, devices according to the present invention may be used for automated seeding machines, or sowing machines, or planting machines such as for planting corn, garlic, trees, salad or the like. Further, devices according to the present invention may be used to assess or monitor weather phenomena, such as clouds, fog, or the like, or to warn from danger of avalanches, tsunamis, gales, earthquakes, thunder storms, or the like. Further, devices according to the present invention may be used to measure motions, shocks, concussions, or the like such as to monitor earthquake risk. Further, devices according to the present invention may be used in traffic technology to monitor dangerous crossings, to control traffic lights depending on traffic, to monitor public spaces, to monitor roads, gyms, stadiums, ski resorts, public events, or the like. Further, devices according to the present invention may be used in medical applications such as to monitor or analyze tissues, medical or biological assays, changes in tissues such as in moles or melanoma or the like, to count bacteria, blood cells, cells, algae, or the like, for retina scans, breath or pulse measurements, gastroscopy, patient surveillance, or the like. Further, devices according to the present invention may be used to monitor the shape, size, or circumference of drops, streams, jets, or the like or to analyze, assess, or monitor profiles or gas or liquid currents such as in a wind channel, or the like. Further,

devices according to the present invention may be used to warn drivers such as car or train drivers when they are getting sick or tired or the like. Further, devices according to the present invention may be used in material testing to recognize strains or tensions or fissures, or the like. Further, devices according to the present invention may be used in sailing to monitor and optimize sail positions such as automatically. Further, devices according to the present invention may be used for fuel level gauges.

Further, the devices according to the present invention may be combined with sensors to detect chemicals or pollutants, electronic nose chips, microbe sensor chips to detect bacteria or viruses or the like, Geiger counters, tactile sensors, heat sensors, or the like. This may for example be used in constructing smart robots which are configured for handling dangerous or difficult tasks, such as in treating highly infectious patients, handling or removing highly dangerous substances, cleaning highly polluted areas, such as highly radioactive areas or chemical spills, or for pest control in agriculture.

One or more devices according to the present invention can further be used for scanning of objects, such as in combination with CAD or similar software, such as for additive manufacturing and/or 3D printing. Therein, use may be made of the high dimensional accuracy of the devices according to the present invention, e.g. in x-, y- or z- direction or in any arbitrary combination of these directions, such as simultaneously. Further, the devices according to the present invention may be used in inspections and maintenance, such as pipeline inspection gauges. Further, in a production environment, the devices according to the present invention may be used to work with objects of a badly defined shape such as naturally grown objects, such as sorting vegetables or other natural products by shape or size or cutting products such as meat or objects that are manufactured with a precision that is lower than the precision needed for a processing step.

Further the devices according to the present invention may be used in local navigation systems to allow autonomously or partially autonomously moving vehicles or multicopters or the like through an indoor or outdoor space. A non-limiting example may comprise vehicles moving through an automated storage for picking up objects and placing them at a different location. Indoor navigation may further be used in shopping malls, retail stores, museums, airports, or train stations, to track the location of mobile goods, mobile devices, baggage, customers or employees, or to supply users with a location specific information, such as the current position on a map, or information on goods sold, or the like.

Further, the devices according to the present invention may be used to ensure safe driving of motorcycles such as driving assistance for motorcycles by monitoring speed, inclination, upcoming obstacles, unevenness of the road, or curves or the like. Further, the devices according to the present invention may be used in trains or trams to avoid collisions.

Further, the devices according to the present invention may be used in handheld devices, such as for scanning packaging or parcels to optimize a logistics process. Further, the devices ac-

According to the present invention may be used in further handheld devices such as personal shopping devices, RFID-readers, handheld devices for use in hospitals or health environments such as for medical use or to obtain, exchange or record patient or patient health related information, smart badges for retail or health environments, or the like.

5

As outlined above, the devices according to the present invention may further be used in manufacturing, quality control or identification applications, such as in product identification or size identification (such as for finding an optimal place or package, for reducing waste etc.). Further, the devices according to the present invention may be used in logistics applications. Thus, the devices according to the present invention may be used for optimized loading or packing containers or vehicles. Further, the devices according to the present invention may be used for monitoring or controlling of surface damages in the field of manufacturing, for monitoring or controlling rental objects such as rental vehicles, and/or for insurance applications, such as for assessment of damages. Further, the devices according to the present invention may be used for identifying a size of material, object or tools, such as for optimal material handling, especially in combination with robots. Further, the devices according to the present invention may be used for process control in production, e.g. for observing filling level of tanks. Further, the devices according to the present invention may be used for maintenance of production assets like, but not limited to, tanks, pipes, reactors, tools etc. Further, the devices according to the present invention may be used for analyzing 3D-quality marks. Further, the devices according to the present invention may be used in manufacturing tailor-made goods such as tooth inlays, dental braces, prosthesis, clothes or the like. The devices according to the present invention may also be combined with one or more 3D-printers for rapid prototyping, 3D-copying or the like. Further, the devices according to the present invention may be used for detecting the shape of one or more articles, such as for anti-product piracy and for anti-counterfeiting purposes.

Thus, specifically, the present application may be applied in the field of photography. Thus, the detector may be part of a photographic device, specifically of a digital camera. Specifically, the detector may be used for 3D photography, specifically for digital 3D photography. Thus, the detector may form a digital 3D camera or may be part of a digital 3D camera. As used herein, the term photography generally refers to the technology of acquiring image information of at least one object. As further used herein, a camera generally is a device adapted for performing photography. As further used herein, the term digital photography generally refers to the technology of acquiring image information of at least one object by using a plurality of light-sensitive elements adapted to generate electrical signals indicating an intensity and/or color of illumination, preferably digital electrical signals. As further used herein, the term 3D photography generally refers to the technology of acquiring image information of at least one object in three spatial dimensions. Accordingly, a 3D camera is a device adapted for performing 3D photography. The camera generally may be adapted for acquiring a single image, such as a single 3D image, or may be adapted for acquiring a plurality of images, such as a sequence of images. Thus, the camera may also be a video camera adapted for video applications, such as for acquiring digital video sequences.

Thus, generally, the present invention further refers to a camera, specifically a digital camera, more specifically a 3D camera or digital 3D camera, for imaging at least one object. As outlined above, the term imaging, as used herein, generally refers to acquiring image information of at least one object. The camera comprises at least one detector according to the present invention. The camera, as outlined above, may be adapted for acquiring a single image or for acquiring a plurality of images, such as image sequence, preferably for acquiring digital video sequences. Thus, as an example, the camera may be or may comprise a video camera. In the latter case, the camera preferably comprises a data memory for storing the image sequence.

As used within the present invention, the expression "position" generally refers to at least one item of information regarding one or more of an absolute position and an orientation of one or more points of the object. Thus, specifically, the position may be determined in a coordinate system of the detector, such as in a Cartesian coordinate system. Additionally or alternatively, however, other types of coordinate systems may be used, such as polar coordinate systems and/or spherical coordinate systems.

As outlined above and as will be outlined in further detail below, the present invention preferably may be applied in the field of human-machine interfaces, in the field of sports and/or in the field of computer games. Thus, preferably, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat, an article of clothing, a hat, a shoe. Other embodiments are feasible.

As used herein, the object generally may be an arbitrary object, chosen from a living object and a non-living object. Thus, as an example, the at least one object may comprise one or more articles and/or one or more parts of an article. Additionally or alternatively, the object may be or may comprise one or more living beings and/or one or more parts thereof, such as one or more body parts of a human being, e.g. a user, and/or an animal.

With regard to the coordinate system for determining the position of the object, which may be a coordinate system of the detector, the detector may constitute a coordinate system in which an optical axis of the detector forms the z-axis and in which, additionally, an x-axis and a y-axis may be provided which are perpendicular to the z-axis and which are perpendicular to each other. As an example, the detector and/or a part of the detector may rest at a specific point in this coordinate system, such as at the origin of this coordinate system. In this coordinate system, a direction parallel or antiparallel to the z-axis may be regarded as a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. An arbitrary direction perpendicular to the longitudinal direction may be considered a transversal direction, and an x- and/or y-coordinate may be considered a transversal coordinate.

Alternatively, other types of coordinate systems may be used. Thus, as an example, a polar coordinate system may be used in which the optical axis forms a z-axis and in which a distance from the z-axis and a polar angle may be used as additional coordinates. Again, a direction parallel or antiparallel to the z-axis may be considered a longitudinal direction, and a coordinate

along the z-axis may be considered a longitudinal coordinate. Any direction perpendicular to the z-axis may be considered a transversal direction, and the polar coordinate and/or the polar angle may be considered a transversal coordinate.

- 5 The detector may be a device configured for providing at least one item of information on the position of the at least one object and/or a part thereof. Thus, the position may refer to an item of information fully describing the position of the object or a part thereof, preferably in the coordinate system of the detector, or may refer to a partial information, which only partially describes the position. The detector generally may be a device adapted for detecting light beams, such as
10 the light beams propagating from the beacon devices towards the detector.

The evaluation device and the detector may fully or partially be integrated into a single device. Thus, generally, the evaluation device also may form part of the detector. Alternatively, the evaluation device and the detector may fully or partially be embodied as separate devices. The
15 detector may comprise further components.

The detector may be a stationary device or a mobile device. Further, the detector may be a stand-alone device or may form part of another device, such as a computer, a vehicle or any other device. Further, the detector may be a hand-held device. Other embodiments of the de-
20 tector are feasible.

The detector specifically may be used to record a light-field behind a lens or lens system of the detector, comparable to a plenoptic or light-field camera. Thus, specifically, the detector may be embodied as a light-field camera adapted for acquiring images in multiple focal planes, such as
25 simultaneously. The term light-field, as used herein, generally refers to the spatial light propagation of light inside the detector such as inside camera. The detector according to the present invention, specifically having a stack of optical sensors, may have the capability of directly recording a light-field within the detector or camera, such as behind a lens. The plurality of sensors may record images at different distances from the lens. Using, e.g., convolution-based al-
30 gorithms such as "depth from focus" or "depth from defocus", the propagation direction, focus points, and spread of the light behind the lens can be modeled. From the modeled propagation of light behind the lens, images at various distances to the lens can be extracted, the depth of field can be optimized, pictures that are in focus at various distances can be extracted, or distances of objects can be calculated. Further information may be extracted.

35 The use of several optical sensors further allows for correcting lens errors in an image processing step after recording the images. Optical instruments often become expensive and challenging in construction, when lens errors need to be corrected. These are especially problematic in microscopes and telescopes. In microscopes, a typical lens error is that rays of varying
40 distance to the optical axis are distorted differently (spherical aberration). In telescopes, varying the focus may occur from differing temperatures in the atmosphere. Static errors such as spherical aberration or further errors from production may be corrected by determining the errors in a calibration step and then using a fixed image processing such as fixed set of pixels and sensor,

or more involved processing techniques using light propagation information. In cases in which lens errors are strongly time-dependent, i.e. dependent on weather conditions in telescopes, the lens errors may be corrected by using the light propagation behind the lens, calculating extended depth of field images, using depth from focus techniques, and others.

5

The detector according to the present invention may further allow for color detection. For color detection, a plurality of optical sensors having different spectral properties may be used, and sensor signals of these optical sensors may be compared. Further, the devices according to the present invention may be used in the context of gesture recognition. In this context, gesture
10 recognition in combination with devices according to the present invention may, in particular, be used as a human-machine interface for transmitting information via motion of a body, of body parts or of objects to a machine. Herein, the information may, preferably, be transmitted via a motion of hands or hand parts, such as fingers, in particular, by pointing at objects, applying sign language, such as for deaf people, making signs for numbers, approval, disapproval, or the
15 like, by waving the hand, such as when asking someone to approach, to leave, or to greet a person, to press an object, to take an object, or, in the field of sports or music, in a hand or finger exercise, such as a warm-up exercise. Further, the information may be transmitted by motion of arms or legs, such as rotating, kicking, grabbing, twisting, rotating, scrolling, browsing, pushing, bending, punching, shaking, arms, legs, both arms, or both legs, or a combination of
20 arms and legs, such as for a purpose of sports or music, such as for entertainment, exercise, or training function of a machine. Further, the information may be transmitted by motion of the whole body or major parts thereof, such as jumping, rotating, or making complex signs, such as sign language used at airports or by traffic police in order to transmit information, such as "turn right", "turn left", "proceed", "slow down", "stop", or "stop engines", or by pretending to swim, to
25 dive, to run, to shoot, or the like, or by making complex motions or body positions such as in yoga, pilates, judo, karate, dancing, or ballet. Further, the information may be transmitted by using a real or mock-up device for controlling a virtual device corresponding to the mock-up device, such as using a mock-up guitar for controlling a virtual guitar function in a computer program, using a real guitar for controlling a virtual guitar function in a computer program, using
30 a real or a mock-up book for reading an e-book or moving pages or browsing through in a virtual document, using a real or mock-up pen for drawing in a computer program, or the like. Further, the transmission of the information may be coupled to a feedback to the user, such as a sound, a vibration, or a motion.

35 In the context of music and/or instruments, devices according to the present invention in combination with gesture recognition may be used for exercising purposes, control of instruments, recording of instruments, playing or recording of music via use of a mock-up instrument or by only pretending to have a instrument present such as playing air guitar, such as to avoid noise or make recordings, or, for conducting of a virtual orchestra, ensemble, band, big band, choir, or
40 the like, for practicing, exercising, recording or entertainment purposes or the like.

Further, in the context of safety and surveillance, devices according to the present invention in combination with gesture recognition may be used to recognize motion profiles of persons, such

as recognizing a person by the way of walking or moving the body, or to use hand signs or movements or signs or movements of body parts or the whole body as access or identification control such as a personal identification sign or a personal identification movement.

- 5 Further, in the context of smart home applications or internet of things, devices according to the present invention in combination with gesture recognition may be used for central or non-central control of household devices which may be part of an interconnecting network of home appliances and/or household devices, such as refrigerators, central heating, air condition, microwave ovens, ice cube makers, or water boilers, or entertainment devices, such as television sets,
10 smart phones, game consoles, video recorders, DVD players, personal computers, laptops, tablets, or combinations thereof, or a combination of household devices and entertainment devices.

- 15 Further, in the context of virtual reality or of augmented reality, devices according to the present invention in combination with gesture recognition may be used to control movements or function of the virtual reality application or of the augmented reality application, such as playing or controlling a game using signs, gestures, body movements or body part movements or the like, moving through a virtual world, manipulating virtual objects, practicing, exercising or playing sports, arts, crafts, music or games using virtual objects such as a ball, chess figures, go
20 stones, instruments, tools, brushes.

- Further, in the context of medicine, devices according to the present invention in combination with gesture recognition may be used to support rehabilitation training, remote diagnostics, or to monitor or survey surgery or treatment, to overlay and display medical images with positions of
25 medical devices, or to overlay display prerecorded medical images such as from magnetic resonance tomography or x-ray or the like with images from endoscopes or ultra sound or the like that are recorded during an surgery or treatment.

- 30 Further, in the context of manufacturing and process automation, devices according to the present invention in combination with gesture recognition may be used to control, teach, or program robots, drones, unmanned autonomous vehicles, service robots, movable objects, or the like, such as for programming, controlling, manufacturing, manipulating, repairing, or teaching purposes, or for remote manipulating of objects or areas, such as for safety reasons, or for maintenance purposes.

- 35 Further, in the context of business intelligence metrics, devices according to the present invention in combination with gesture recognition may be used for people counting, surveying customer movements, areas where customers spend time, objects, customers test, take, probe, or the like.

- 40 Further, devices according to the present invention may be used in the context of do-it-yourself or professional tools, especially electric or motor driven tools or power tools, such as drilling machines, saws, chisels, hammers, wrenches, staple guns, disc cutters, metals shears and nib-

blers, angle grinders, die grinders, drills, hammer drills, heat guns, wrenches, sanders, engravers, nailers, jig saws, biscuit joiners, wood routers, planers, polishers, tile cutters, washers, rollers, wall chasers, lathes, impact drivers, jointers, paint rollers, spray guns, morticers, or welders, in particular, to support precision in manufacturing, keeping a minimum or maximum distance, or for safety measures.

Further, the devices according to the present invention may be used to aid visually impaired persons. Further, devices according to the present invention may be used in touch screen such as to avoid direct contact such as for hygienic reasons, which may be used in retail environments, in medical applications, in production environments, or the like. Further, devices according to the present invention may be used in agricultural production environments such as in stable cleaning robots, egg collecting machines, milking machines, harvesting machines, farm machinery, harvesters, forwarders, combine harvesters, tractors, cultivators, ploughs, destoners, harrows, strip tills, broadcast seeders, planters such as potato planters, manure spreaders, sprayers, sprinkler systems, swathers, balers, loaders, forklifts, mowers, or the like.

Further, devices according to the present invention may be used for selection and/or adaption of clothing, shoes, glasses, hats, prosthesis, dental braces, for persons or animals with limited communication skills or possibilities, such as children or impaired persons, or the like. Further, devices according to the present invention may be used in the context of warehouses, logistics, distribution, shipping, loading, unloading, smart manufacturing, industry 4.0, or the like. Further, in a manufacturing context, devices according to the present invention may be used in the context of processing, dispensing, bending, material handling, or the like.

The evaluation device may be or may comprise one or more integrated circuits, such as one or more application-specific integrated circuits (ASICs), and/or one or more data processing devices, such as one or more computers, preferably one or more microcomputers and/or microcontrollers, Field Programmable Arrays, or Digital Signal Processors. Additional components may be comprised, such as one or more preprocessing devices and/or data acquisition devices, such as one or more devices for receiving and/or preprocessing of the sensor signals, such as one or more AD-converters and/or one or more filters. Further, the evaluation device may comprise one or more measurement devices, such as one or more measurement devices for measuring electrical currents and/or electrical voltages. Further, the evaluation device may comprise one or more data storage devices. Further, the evaluation device may comprise one or more interfaces, such as one or more wireless interfaces and/or one or more wire-bound interfaces.

The at least one evaluation device may be adapted to perform at least one computer program, such as at least one computer program adapted for performing or supporting one or more or even all of the method steps of the method according to the present invention. As an example, one or more algorithms may be implemented which, by using the sensor signals as input variables, may determine the position of the object.

The evaluation device can be connected to or may comprise at least one further data processing device that may be used for one or more of displaying, visualizing, analyzing, distributing, communicating or further processing of information, such as information obtained by the optical sensor and/or by the evaluation device. The data processing device, as an example, may be connected or incorporate at least one of a display, a projector, a monitor, an LCD, a TFT, a loudspeaker, a multichannel sound system, an LED pattern, or a further visualization device. It may further be connected or incorporate at least one of a communication device or communication interface, a connector or a port, capable of sending encrypted or unencrypted information using one or more of email, text messages, telephone, Bluetooth, Wi-Fi, infrared or internet interfaces, ports or connections. It may further be connected or incorporate at least one of a processor, a graphics processor, a CPU, an Open Multimedia Applications Platform (OMAP™), an integrated circuit, a system on a chip such as products from the Apple A series or the Samsung S3C2 series, a microcontroller or microprocessor, one or more memory blocks such as ROM, RAM, EEPROM, or flash memory, timing sources such as oscillators or phase-locked loops, counter-timers, real-time timers, or power-on reset generators, voltage regulators, power management circuits, or DMA controllers. Individual units may further be connected by buses such as AMBA buses or be integrated in an Internet of Things or Industry 4.0 type network.

The evaluation device and/or the data processing device may be connected by or have further external interfaces or ports such as one or more of serial or parallel interfaces or ports, USB, Centronics Port, FireWire, HDMI, Ethernet, Bluetooth, RFID, Wi-Fi, USART, or SPI, or analogue interfaces or ports such as one or more of ADCs or DACs, or standardized interfaces or ports to further devices such as a 2D-camera device using an RGB-interface such as CameraLink. The evaluation device and/or the data processing device may further be connected by one or more of interprocessor interfaces or ports, FPGA-FPGA-interfaces, or serial or parallel interfaces ports. The evaluation device and the data processing device may further be connected to one or more of an optical disc drive, a CD-RW drive, a DVD+RW drive, a flash drive, a memory card, a disk drive, a hard disk drive, a solid state disk or a solid state hard disk.

The evaluation device and/or the data processing device may be connected by or have one or more further external connectors such as one or more of phone connectors, RCA connectors, VGA connectors, hermaphrodite connectors, USB connectors, HDMI connectors, 8P8C connectors, BCN connectors, IEC 60320 C14 connectors, optical fiber connectors, D-subminiature connectors, RF connectors, coaxial connectors, SCART connectors, XLR connectors, and/or may incorporate at least one suitable socket for one or more of these connectors.

Possible embodiments of a single device incorporating one or more of the detectors according to the present invention, the evaluation device or the data processing device, such as incorporating one or more of the optical sensor, optical systems, evaluation device, communication device, data processing device, interfaces, system on a chip, display devices, or further electronic devices, are: mobile phones, personal computers, tablet PCs, televisions, game consoles or further entertainment devices. In a further embodiment, the 3D-camera functionality which

will be outlined in further detail below may be integrated in devices that are available with conventional 2D-digital cameras, without a noticeable difference in the housing or appearance of the device, where the noticeable difference for the user may only be the functionality of obtaining and or processing 3D information. Further, devices according to the present invention may be used in 360° digital cameras or surround view cameras.

Specifically, an embodiment incorporating the detector and/or a part thereof such as the evaluation device and/or the data processing device may be: a mobile phone incorporating a display device, a data processing device, the optical sensor, optionally the sensor optics, and the evaluation device, for the functionality of a 3D camera. The detector according to the present invention specifically may be suitable for integration in entertainment devices and/or communication devices such as a mobile phone.

A further embodiment of the present invention may be an incorporation of the detector or a part thereof such as the evaluation device and/or the data processing device in a device for use in automotive, for use in autonomous driving or for use in car safety systems such as Daimler's Intelligent Drive system, wherein, as an example, a device incorporating one or more of the optical sensors, optionally one or more optical systems, the evaluation device, optionally a communication device, optionally a data processing device, optionally one or more interfaces, optionally a system on a chip, optionally one or more display devices, or optionally further electronic devices may be part of a vehicle, a car, a truck, a train, a bicycle, an airplane, a ship, a motorcycle. In automotive applications, the integration of the device into the automotive design may necessitate the integration of the optical sensor, optionally optics, or device at minimal visibility from the exterior or interior. The detector or a part thereof such as the evaluation device and/or the data processing device may be especially suitable for such integration into automotive design.

As used herein, the term light generally refers to electromagnetic radiation in one or more of the visible spectral range, the ultraviolet spectral range and the infrared spectral range. Therein, the term visible spectral range generally refers to a spectral range of 380 nm to 780 nm. The term infrared spectral range generally refers to electromagnetic radiation in the range of 780 nm to 1 mm, preferably in the range of 780 nm to 3.0 micrometers. The term ultraviolet spectral range generally refers to electromagnetic radiation in the range of 1 nm to 380 nm, preferably in the range of 100 nm to 380 nm. Preferably, light as used within the present invention is visible light, i.e. light in the visible spectral range.

The term light beam generally may refer to an amount of light emitted and/or reflected into a specific direction. Thus, the light beam may be a bundle of the light rays having a predetermined extension in a direction perpendicular to a direction of propagation of the light beam. Preferably, the light beams may be or may comprise one or more Gaussian light beams such as a linear combination of Gaussian light beams, which may be characterized by one or more Gaussian beam parameters, such as one or more of a beam waist, a Rayleigh-length or any other beam parameter or combination of beam parameters suited to characterize a development of a beam diameter and/or a beam propagation in space.

The detector according to the present invention may further be combined with one or more other types of sensors or detectors. Thus, the detector may further comprise at least one additional detector. The at least one additional detector may be adapted for detecting at least one parameter, such as at least one of: a parameter of a surrounding environment, such as a temperature and/or a brightness of a surrounding environment; a parameter regarding a position and/or orientation of the detector; a parameter specifying a state of the object to be detected, such as a position of the object, e.g. an absolute position of the object and/or an orientation of the object in space. Thus, generally, the principles of the present invention may be combined with other measurement principles in order to gain additional information and/or in order to verify measurement results or reduce measurement errors or noise.

As outlined above, the human-machine interface may comprise a plurality of beacon devices which are adapted to be at least one of directly or indirectly attached to the user and held by the user. Thus, the beacon devices each may independently be attached to the user by any suitable means, such as by an appropriate fixing device. Additionally or alternatively, the user may hold and/or carry the at least one beacon device or one or more of the beacon devices in his or her hands and/or by wearing the at least one beacon device and/or a garment containing the beacon device on a body part.

The beacon device generally may be an arbitrary device which may be detected by the at least one detector and/or which facilitates detection by the at least one detector. Thus, as outlined above or as will be outlined in further detail below, the beacon device may be an active beacon device adapted for generating the at least one light beam to be detected by the detector, such as by having one or more illumination sources for generating the at least one light beam. Additionally or alternatively, the beacon device may fully or partially be designed as a passive beacon device, such as by providing one or more reflective elements adapted to reflect a light beam generated by a separate illumination source. The at least one beacon device may permanently or temporarily be attached to the user in a direct or indirect way and/or may be carried or held by the user. The attachment may take place by using one or more attachment means and/or by the user himself or herself, such as by the user holding the at least one beacon device by hand and/or by the user wearing the beacon device.

Additionally or alternatively, the beacon devices may be at least one of attached to an object and integrated into an object held by the user, which, in the sense of the present invention, shall be included into the meaning of the option of the user holding the beacon devices. Thus, as will be outlined in further detail below, the beacon devices may be attached to or integrated into a control element which may be part of the human-machine interface and which may be held or carried by the user, and of which the orientation may be recognized by the detector device.

Thus, generally, the present invention also refers to a detector system comprising at least one detector device according to the present invention and which, further, may comprise at least one object, wherein the beacon devices are one of attached to the object, held by the object and integrated into the object. As an example, the object preferably may form a control element,

the orientation of which may be recognized by a user. Thus, the detector system may be part of the human-machine interface as outlined above or as outlined in further detail below. As an example, the user may handle the control element in a specific way in order to transmit one or more items of information to a machine, such as in order to transmit one or more commands to the machine.

Alternatively, the detector system may be used in other ways. Thus, as an example, the object of the detector system may be different from a user or a body part of the user and, as an example, may be an object which moves independently from the user. As an example, the detector system may be used for controlling apparatuses and/or industrial processes, such as manufacturing processes and/or robotics processes. Thus, as an example, the object may be a machine and/or a machine part, such as a robot arm, the orientation of which may be detected by using the detector system.

The human-machine interface may be adapted in such a way that the detector device generates at least one item of information on the position of the user or of at least one body part of the user. Specifically in case a manner of attachment of the at least one beacon device to the user is known, by evaluating the position of the at least one beacon device, at least one item of information on a position and/or an orientation of the user or of a body part of the user may be gained.

The beacon device preferably is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user. As outlined above, the beacon device may fully or partially be designed as an active beacon device. Thus, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be transmitted to the detector, preferably at least one light beam having known beam properties. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

The object, which may form part of the detector system, may generally have an arbitrary shape. Preferably, the object being part of the detector system, as outlined above, may be a control element which may be handled by a user, such as manually. As an example, the control element may be or may comprise at least one element selected from the group consisting of: a glove, a jacket, a hat, shoes, trousers and a suit, a stick that may be held by hand, a bat, a club, a racket, a cane, a toy, such as a toy gun. Thus, as an example, the detector system may be part of the human-machine interface and/or of the entertainment device.

As used herein, an entertainment device is a device which may serve the purpose of leisure and/or entertainment of one or more users, in the following also referred to as one or more players. As an example, the entertainment device may serve the purpose of gaming, preferably computer gaming. Thus, the entertainment device may be implemented into a computer, a

computer network or a computer system or may comprise a computer, a computer network or a computer system which runs one or more gaming software programs.

5 The entertainment device comprises at least one human-machine interface according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed below. The entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface. The at least one item of information may be transmitted to and/or may be used by a controller and/or a computer of the entertainment device. The at least one
10 item of information preferably may comprise at least one command adapted for influencing the course of a game. Thus, as an example, the at least one item of information may include at least one item of information on at least one orientation of the player and/or of one or more body parts of the player, thereby allowing for the player to simulate a specific position and/or orientation and/or action required for gaming. As an example, one or more of the following movements
15 may be simulated and communicated to a controller and/or a computer of the entertainment device: dancing; running; jumping; swinging of a racket; swinging of a bat; swinging of a club; pointing of an object towards another object, such as pointing of a toy gun towards a target.

20 The entertainment device as a part or as a whole, preferably a controller and/or a computer of the entertainment device, is designed to vary the entertainment function in accordance with the information. Thus, as outlined above, a course of a game might be influenced in accordance with the at least one item of information. Thus, the entertainment device might include one or more controllers which might be separate from the evaluation device of the at least one detector and/or which might be fully or partially identical to the at least one evaluation device or which
25 might even include the at least one evaluation device. Preferably, the at least one controller might include one or more data processing devices, such as one or more computers and/or microcontrollers.

30 As further used herein, a tracking system is a device which is adapted to gather information on a series of past positions of the at least one object and/or at least one part of the object. Additionally, the tracking system may be adapted to provide information on at least one predicted future position and/or orientation of the at least one object or the at least one part of the object. The tracking system may have at least one track controller, which may fully or partially be embodied as an electronic device, preferably as at least one data processing device, more preferably as at least one computer or microcontroller. Again, the at least one track controller may
35 fully or partially comprise the at least one evaluation device and/or may be part of the at least one evaluation device and/or may fully or partially be identical to the at least one evaluation device.

40 The tracking system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the

object at specific points in time, such as by recording groups of data or data pairs, each group of data or data pair comprising at least one position information and at least one time information.

- 5 The tracking system may further comprise the at least one detector system according to the present invention. Thus, besides the at least one detector and the at least one evaluation device and the optional at least one beacon device, the tracking system may further comprise the object itself or a part of the object, such as at least one control element comprising the beacon devices or at least one beacon device, wherein the control element is directly or indirectly at-
10 tachable to or integratable into the object to be tracked.

The tracking system may be adapted to initiate one or more actions of the tracking system itself and/or of one or more separate devices. For the latter purpose, the tracking system, preferably the track controller, may have one or more wireless and/or wire-bound interfaces and/or other
15 types of control connections for initiating at least one action. Preferably, the at least one track controller may be adapted to initiate at least one action in accordance with at least one actual position of the object. As an example, the action may be selected from the group consisting of: a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detec-
20 tor.

As an example of application of a tracking system, the tracking system may be used for continuously pointing at least one first object to at least one second object even though the first object and/or the second object might move. Potential examples, again, may be found in industrial
25 applications, such as in robotics and/or for continuously working on an article even though the article is moving, such as during manufacturing in a manufacturing line or assembly line. Additionally or alternatively, the tracking system might be used for illumination purposes, such as for continuously illuminating the object by continuously pointing an illumination source to the object even though the object might be moving. Further applications might be found in communication
30 systems, such as in order to continuously transmit information to a moving object by pointing a transmitter towards the moving object.

The detector according to the present invention may be realized as a simple device combining the functionality of distance measurement or measurement of z-coordinates, with the additional
35 option of measuring one or more transversal coordinates, thereby integrating the functionality of a PSD.

When mentioning a range of measurement, the range of measurement may both refer to a range of brightness which may be used with the detector according to the present invention,
40 such as a range of total powers of the light beam, or may refer to a range of distances between the detector and the object which may be measured. Conventional detectors, such as according to one or more of the documents listed above, are typically limited in both ranges of measurement. The use of the quotient signal, as mentioned above, contrarily, provides a wide range of a

continuously and monotonously decreasing or increasing functions which may be used to determine the longitudinal coordinate from the quotient signal. Consequently, a very wide range of measurement in terms of distance between the object and the detector is given. Similarly, due to the general independence of the quotient signal from the total power of the light beam, at least as long as no saturation of one or both of the optical sensors is reached, also provides a very wide range of measurement in terms of brightness, i.e. in terms of total power of the light beam.

The light beam, within the detector, generally may propagate along an optical axis of the detector. The first and second optical sensors may be placed on the optical axis. The light beam, however, may also propagate in other ways than along the optical axis. As an example, an illumination light beam may be generated which propagates along the optical axis or which propagates parallel to the optical axis or at an angle to the optical axis which is different from 0° , such as an angle of 1° to 20° . Other embodiments are feasible.

Overall, in the context of the present invention, the following embodiments are regarded as preferred:

Embodiment 1: A detector for determining a position of at least one object, the detector comprising:

- at least one transfer device, wherein the transfer device has at least one focal length in response to at least one incident light beam propagating from the object to the detector;
- at least two optical sensors, wherein each optical sensor has at least one light sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by the light beam,
- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating a quotient signal Q from the sensor signals.

Embodiment 2: The detector according to the preceding embodiment, wherein the detector is adapted to determine the longitudinal coordinate z of the object in at least one measurement range independent from the object size in an object plane.

Embodiment 3: The detector according to any one of the preceding embodiments, wherein the measurement range is adjustable by adjusting on one or more parameters selected from the group consisting of: a longitudinal distance from the object to the transfer device z_0 ; the focal length of the transfer device f ; a diameter of an exit pupil of the transfer device E_x ; a longitudinal distance from the transfer device to the light sensitive area z_s , a distance from the transfer device to an image of the object z_i ; an object size O_{size} of the object in the object plane.

Embodiment 4: The detector according to the preceding embodiment, wherein the detector is adapted to determine the longitudinal coordinate z of the object independent from the object

size if a circle of confusion of at least one light beam emitted from at least one point of the object is greater than an image size of the object.

Embodiment 5: The detector according to the preceding embodiment, wherein the detector is adapted to determine the longitudinal coordinate z of the object independent from the object size if $O_{size} < \frac{z_0 E_x}{z_i^2} |z_s - z_i|$ holds true for at least one distance.

Embodiment 6: The detector according to the preceding embodiment, wherein the evaluation device is configured for deriving the quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

Embodiment 7: The detector according to the preceding embodiment, wherein the evaluation device is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate for determining the longitudinal coordinate.

Embodiment 8: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for deriving the quotient signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A_1 and A_2 are areas of the beam profile at the sensor position, and $E(x, y, z_o)$ denotes the beam profile given at the object distance z_o .

Embodiment 9: The detector according to any one of the preceding embodiments, wherein the optical sensors are positioned off focus.

Embodiment 10: The detector according to any one of the preceding embodiments, wherein the transfer device has an optical axis, wherein the transfer device constitutes a coordinate system, wherein a longitudinal coordinate l is a coordinate along the optical axis and wherein d is a spatial offset from the optical axis, wherein the optical sensors are arranged such that the light-sensitive areas of the optical sensors differ in at least one of: their longitudinal coordinate, their spatial offset, or their surface areas.

Embodiment 11: The detector according to any one of the preceding embodiments, wherein the light beam may be a monochromatic light beam.

Embodiment 12: The detector according to any one of the preceding embodiments, wherein each of the sensor signals comprises at least one information of at least one area of the beam profile of at least one beam profile of the light beam.

Embodiment 13: The detector according to the preceding embodiment, wherein the beam profile is selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles.

5

Embodiment 14: The detector according to any one of the two preceding embodiments, wherein the light-sensitive regions are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.

10

Embodiment 15: The detector according to the preceding embodiment, wherein the evaluation device is configured to determine the first area of the beam profile and the second area of the beam profile.

15

Embodiment 16: The detector according to any one of the four preceding embodiments, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile.

20

Embodiment 17: The detector according to any one of the preceding embodiments, wherein the edge information comprises an information relating to a number of photons in the first area of the beam profile and the center information comprises an information relating to a number of photons in the second area of the beam profile.

25

Embodiment 18: The detector according to any one of the two the preceding embodiments, wherein the evaluation device is configured to derive the quotient signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information.

30

Embodiment 19: The detector according to any one of the three preceding embodiments, wherein the light beam propagating from the object to the detector illuminates the optical sensors with at least one line pattern, wherein A1 corresponds to an area with a full line width of the line pattern on the optical sensors, wherein A2 is a central area of the line pattern on the optical sensors.

35

Embodiment 20: The detector according to any one of the four preceding embodiments, wherein the light beam propagating from the object to the detector illuminates the optical sensor with at least one point pattern, wherein A1 corresponds to an area with a full radius of a point of the point pattern on the optical sensors, wherein A2 is a central area of the point in the point pattern on the optical sensors.

40

Embodiment 21: The detector according to any one of the preceding embodiments, wherein the optical sensors comprise a first optical sensor having a first light sensitive area and a second optical sensor having a second light sensitive area, wherein the first and the second light sensitive areas are arranged such that a condition

$$\frac{a}{c} \neq \frac{b}{d}$$

- 5 is satisfied, wherein "a" is a ratio of photons hitting both an inner region of a plane perpendicular to the optical axis intersecting the optical axis at a distance equal to half of a focal length of the transfer device and the first light sensitive area, "b" is a ratio of photons hitting both the inner region of the plane and the second light sensitive area, "c" is a ratio of photons hitting both an outer region of the plane and the first light-sensitive area, "d" is a ratio of the photons hitting
10 both the outer region of the plane and the second light sensitive area.

Embodiment 22: The detector according to the preceding embodiment, wherein the first light sensitive area and the second light sensitive area are arranged such that the inner region has an area with a geometrical center point on the optical axis and an extension such that half of the
15 photons hit the plane within the inner region and the other half hit the plane outside the inner region.

Embodiment 23: The detector according to the preceding embodiment, wherein the first light sensitive area and the second light sensitive area are arranged such that the inner region is
20 designed as a circle with a center point on the optical axis and a radius r which is chosen such that half of the photons hit the plane within the circle and the other half hit the plane outside the circle.

- Embodiment 24: A detector for determining a position of at least one object, the detector having
25
- at least one first optical sensor having a first light-sensitive area, wherein the first optical sensor is configured to generate at least one first sensor signal in response to an illumination of the first light-sensitive area by a light beam propagating from the object to the detector;
 - at least one second optical sensor having a second light-sensitive area, wherein the
30 second optical sensor is configured to generate at least one second sensor signal in response to an illumination of the second light-sensitive area by the light beam, wherein the first light-sensitive area is smaller than the second light-sensitive area; and
 - at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating the first and second sensor signals.
35

Embodiment 25: The detector according to the preceding embodiment, wherein the evaluation device is configured for deriving a quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals, wherein the evaluation device is configured for determining the longitudinal coordinate by evaluating the quotient signal Q.
40

Embodiment 26: The detector according to the preceding embodiment, wherein the evaluation device is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate.

- 5 Embodiment 27: The detector according to the preceding embodiment, wherein the predetermined relationship is one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship.

- 10 Embodiment 28: The detector according to any one of the two preceding embodiments, wherein the evaluation device comprises at least one data storage device for storing the predetermined relationship.

- 15 Embodiment 29: The detector according to any one of the four preceding embodiments, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the quotient signal.

Embodiment 30: The detector according to the preceding embodiment, wherein the divider is fully or partially embodied as one or both of a software divider or a hardware divider.

- 20 Embodiment 31: The detector according to any one of the seven preceding embodiments, wherein the first and second optical sensors are arranged linearly in one and the same beam path of the detector.

- 25 Embodiment 32: The detector according to the preceding embodiment, wherein the first and second optical sensors are arranged concentrically with respect to an optical axis of the detector.

- 30 Embodiment 33: The detector according to any one of the eight preceding embodiments, wherein the first optical sensor is arranged in front of the second optical sensor and is spaced apart from the second optical sensor by no more than five times the square root of a surface area of the first light-sensitive area.

- 35 Embodiment 34: The detector according to any one of the nine preceding embodiments, wherein the first optical sensor is arranged in front of the second optical sensor and is spaced apart from the second optical sensor by no more than 50 mm, preferably by no more than 15 mm.

- 40 Embodiment 35: The detector according to any one of the ten preceding embodiments, wherein the second light-sensitive area is larger by at least a factor of two, more preferably by at least a factor of three and most preferably by at least a factor of five as compared to the first light-sensitive area.

Embodiment 36: The detector according to any one of the eleven preceding embodiments, wherein the first light-sensitive area has a surface area of 1 mm² to 150 mm², more preferably a surface area of 10 mm² to 100 mm².

- 5 Embodiment 37: The detector according to any one of the twelve preceding embodiments, specifically according to the preceding embodiment, wherein the second light-sensitive area has a surface area of 160 mm² to 1000 mm², more preferably a surface area of 200 mm² to 600 mm².

- 10 Embodiment 38: The detector according to any one of the thirteen preceding embodiments, wherein the first and second optical sensor each have, at least within a range of measurement, a linear signal characteristic such that the respective first and second sensor signals are dependent on the total power of illumination of the respective optical sensor and are independent from a diameter of a light spot of the illumination.

- 15 Embodiment 39: The detector according to any one of the fourteen preceding embodiments, wherein the first and second optical sensors each are semiconductor sensors, preferably inorganic semiconductor sensors, more preferably photodiodes and most preferably silicon photodiodes.

- 20 Embodiment 40: The detector according to any one of the fifteen preceding embodiments, wherein the first and second optical sensors each are uniform sensors having a single light-sensitive area each.

- 25 Embodiment 41: The detector according to any one of the sixteen preceding embodiments, wherein the detector further comprises an illumination source for illuminating the object.

- 30 Embodiment 42: The detector according to the preceding embodiment, wherein the illumination source is configured for generating an illuminating light beam for illuminating the object, wherein the detector is configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector.

- 35 Embodiment 43: The detector according to the preceding embodiment, wherein the detector comprises at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

- 40 Embodiment 44: The detector according to any one of the three preceding embodiments, wherein the illumination source is adapted to generate at least one illumination pattern for illumination of the object, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern or a random point pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern, in particular a rotated hexagonal pattern and/or a displaced hexagonal pattern; at least one rectangular pattern at least one pat-

tern comprising convex uniform tilings; at least one fringe pattern; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines.

5 Embodiment 45: The detector according to the preceding embodiment, wherein the optical sensors are adapted to determine at least one reflection pattern, wherein the evaluation device is adapted to select at least one feature of the reflection pattern and to determine the longitudinal coordinate z of the selected feature of the reflection pattern by evaluating the quotient signal Q .

10 Embodiment 46: The detector according to any one of the twenty-one preceding embodiments, wherein the detector further comprises at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensors.

15 Embodiment 47: The detector according to the preceding embodiment, wherein the transfer device comprises one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

20 Embodiment 48: The detector according to any one of the twenty-three preceding embodiments, wherein the first light-sensitive area, in a direction of propagation of the light beam, overlaps with the second light-sensitive area.

25 Embodiment 49: A detector for determining a position of at least one object, the detector having - at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor is configured to generate at least one sensor signal in response to an illumination of the light-sensitive area by at least one light beam propagating from the object to the detector;

30 - at least one evaluation device configured for evaluating the sensor signals, by
a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one
35 sum signal;
c) determining at least one combined signal by combining the center signal and the sum signal; and
d) determining at least one longitudinal coordinate z of the object by evaluating the combined
40 signal.

Embodiment 50: The detector according to the preceding embodiment, wherein the center signal is selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal;

an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

Embodiment 51: The detector according to any one of the two preceding embodiments, wherein the detector, specifically the evaluation device, is configured for transforming the sensor signals of the optical sensor, thereby generating secondary optical sensor signals, wherein the evaluation device is configured for performing steps a)-d) by using the secondary optical sensor signals.

Embodiment 52: The detector according to the preceding embodiment, wherein the transforming of the sensor signals comprises at least one transformation selected from the group consisting of: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue, saturation, and brightness channels, a frequency decomposition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image.

Embodiment 53: The detector according to any one of the four preceding embodiments, wherein the evaluation device comprises at least one center detector for detecting the at least one highest sensor signal and/or for forming the center signal.

Embodiment 54: The detector according to the preceding embodiment, wherein the center detector is fully or partially integrated into the sensor element.

Embodiment 55: The detector according to any one of the two preceding embodiments, wherein the center detector is fully or partially embodied in one or both of software or hardware.

Embodiment 56: The detector according to any one of the seven preceding embodiments, wherein the sum signal is selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; an integral of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal.

Embodiment 57: The detector according to the preceding embodiment, wherein the evaluation device comprises at least one summing device for forming the sum signal.

Embodiment 58: The detector according to the preceding embodiment, wherein the summing device is fully or partially integrated into the sensor element.

Embodiment 59: The detector according to any one of the two preceding embodiments, wherein the summing device is fully or partially embodied in one or both of software or hardware.

Embodiment 60: The detector according to any one of the eleven preceding embodiments, wherein the combined signal is a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal.

Embodiment 61: The detector according to the preceding embodiment, wherein the evaluation device is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate for determining the longitudinal coordinate.

Embodiment 62: The detector according to the preceding embodiment, wherein the predetermined relationship is one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship.

Embodiment 63: The detector according to any one of the two preceding embodiments, wherein the evaluation device comprises at least one data storage device for storing the predetermined relationship.

Embodiment 64: The detector according to any one of the four preceding embodiments, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the quotient signal.

5

Embodiment 65: The detector according to the preceding embodiment, wherein the divider is fully or partially embodied as one or both of a software divider or a hardware divider.

Embodiment 66: The detector according to any one of the two preceding embodiments, wherein the divider is fully or partially integrated into the sensor element.

10

Embodiment 67: The detector according to any one of the eighteen preceding embodiments, wherein the optical sensors are photodetectors, preferably inorganic photodetectors, more preferably inorganic semiconductor photodetectors, most preferably silicon photodetectors.

15

Embodiment 68: The detector according to any one of the nineteen preceding embodiments, wherein the optical sensors are sensitive in the infrared spectral range.

Embodiment 69: The detector according to any one of the twenty preceding embodiments, wherein the matrix comprises one or both of a CCD detector, preferably a CCD detector chip, or a CMOS detector, preferably a CMOS detector chip.

20

Embodiment 70: The detector according to any one of the twenty-one preceding embodiments, wherein the matrix is a rectangular matrix having at least one row, preferably a plurality of rows, and a plurality of columns.

25

Embodiment 71: The detector according to the preceding embodiment, wherein the rows and columns are oriented essentially perpendicular.

Embodiment 72: The detector according to any one of the two preceding embodiments, wherein the matrix has at least 10 rows, preferably at least 50 rows, more preferably at least 100 rows.

30

Embodiment 73: The detector according to any one of the three preceding embodiments, wherein the matrix has at least 10 columns, preferably at least 50 columns, more preferably at least 100 columns.

35

Embodiment 74: The detector according to any one of the four preceding embodiments, wherein the ratio of the number of rows and the number of columns is close to 1 preferable larger than 1:3, more preferably larger than 1:2.

40

Embodiment 75: The detector according to any one of the twenty-six preceding embodiments, wherein the matrix comprises at least 50 optical sensors, preferably at least 100 optical sensors, more preferably at least 500 optical sensors.

Embodiment 76: The detector according to any one of the twenty-seven preceding embodiments, wherein the sensor element is oriented essentially perpendicular to an optical axis of the detector.

5

Embodiment 77: The detector according to any one of the twenty-eight preceding embodiments, wherein the optical sensors each have, at least within a range of measurement, a linear signal characteristic such that the respective sensor signals are dependent on the total power of illumination of the respective optical sensor.

10

Embodiment 78: The detector according to any one of the twenty-nine preceding embodiments, wherein the detector further comprises an illumination source for illuminating the object.

Embodiment 79: The detector according to the preceding embodiment, wherein the illumination source is configured for generating an illuminating light beam for illuminating the object, wherein the detector is configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector.

15

Embodiment 80: The detector according to the preceding embodiment, wherein the detector comprises at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

20

Embodiment 81: The detector according to any one of the three preceding embodiments, wherein the illumination source is adapted to generate at least one illumination pattern for illumination of the object, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern or a random point pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern, in particular a rotated hexagonal pattern and/or a displaced hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one fringe pattern; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines.

25

30

Embodiment 82: The detector according to the preceding embodiment, wherein the optical sensors are adapted to determine at least one reflection pattern, wherein the evaluation device is adapted to select at least one feature of the reflection pattern and to determine the longitudinal coordinate z of the selected feature of the reflection pattern by evaluating the quotient signal Q .

35

Embodiment 83: The detector according to any one of the thirty-four preceding embodiments, wherein the detector further comprises at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensors.

40

Embodiment 84: The detector according to the preceding embodiment, wherein the transfer device comprises one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

Embodiment 85: The detector according to any one of the thirty-six preceding embodiments, wherein the evaluation device is further configured for determining at least one transversal coordinate of the object by evaluating a transversal position of the at least one optical sensor having the highest sensor signal.

Embodiment 86: The detector according to any one of the thirty-eight preceding embodiments, wherein the evaluation device is configured for distinguishing different light beams having different modulations.

Embodiment 87: A detector for determining a position of at least one object, the detector having

- at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different spatial offsets, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by a light beam propagating from the object to the detector; and
- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by combining the at least two sensor signals.

Embodiment 88: The detector according to the preceding embodiment, wherein the optical sensors are located in the same plane.

Embodiment 89: The detector according to any one of the two preceding embodiments, wherein the optical sensors are partial diodes of a segmented diode, with a center of the segmented diode being off-centered from the optical axis of the detector.

Embodiment 90: The detector according to any one of the three preceding embodiments, wherein the optical sensors are part of a sensor array, such as an array comprising 2-4 optical sensors such as a quadrant photodiode.

Embodiment 91: The detector according to the preceding embodiment, wherein a geometrical center of the sensor array is offset from the optical axis.

Embodiment 92: The detector according to any one of the two preceding embodiments, wherein the sensor array is movable, preferably automatically, relative to the optical axis.

Embodiment 93: The detector according to the preceding embodiment, wherein the evaluation device is configured for, firstly, determining the at least one transversal position of a light spot generated by the light beam on the sensor array by using the sensor signals and for, secondly,
5 moving the sensor array relative to the optical axis until the light spot is off-centered.

Embodiment 94: The detector according to any one of the seven preceding embodiments, wherein the optical sensors are partial diodes of a quadrant diode, with a geometrical center of the quadrant diode being off-centered from the optical axis of the detector.
10

Embodiment 95: The detector according to any one of the eight preceding embodiments, wherein the light-sensitive areas of the optical sensors are equal.

Embodiment 96: The detector according to any one of the nine preceding embodiments, wherein the detector comprises at least one lens, wherein the optical axis of the detector is an axis of symmetry of the lens.
15

Embodiment 97: The detector according to any one of the ten preceding embodiments, wherein the evaluation device is configured for deriving a quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals, and wherein the evaluation device is further configured for determining the longitudinal coordinate by evaluating the quotient signal Q .
20

Embodiment 98: The detector according to the preceding embodiment, wherein the evaluation device is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate.
25

Embodiment 99: The detector according to the preceding embodiment, wherein the predetermined relationship is one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship.
30

Embodiment 100: The detector according to any one of the two preceding embodiments, wherein the evaluation device comprises at least one data storage device for storing the predetermined relationship.
35

Embodiment 101: The detector according to any one of the four preceding embodiments, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the quotient signal.

Embodiment 102: The detector according to the preceding embodiment, wherein the divider is fully or partially embodied as one or both of a software divider or a hardware divider.
40

Embodiment 103: The detector according to any one of the sixteen preceding embodiments, wherein the optical sensors are arranged in one and the same beam path of the detector.

Embodiment 104: The detector according to any one of the seventeen preceding embodiments, wherein the optical sensors each are semiconductor sensors, preferably inorganic semiconductor sensors, more preferably photodiodes and most preferably silicon photodiodes.

5

Embodiment 105: The detector according to any one of the eighteen preceding embodiments, wherein the optical sensors each are uniform sensors having a single light-sensitive area each.

Embodiment 106: The detector according to any one of the nineteen preceding embodiments, wherein the optical sensors each have, at least within a range of measurement, a linear signal characteristic such that the sensor signals are dependent on the total power of illumination of the respective optical sensor and are independent from a diameter of a light spot of the illumination.

10

Embodiment 107: The detector according to any one of the twenty preceding embodiments, wherein the detector further comprises an illumination source for illuminating the object, e.g. an illumination source comprising at least one laser, such as an illumination source providing at least one illuminating light beam being on the optical axis or being not on the optical axis.

15

Embodiment 108: The detector according to the preceding embodiment, wherein the illumination source is configured for generating an illuminating light beam for illuminating the object, wherein the detector is configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector.

20

Embodiment 109: The detector according to the preceding embodiment, wherein the detector comprises at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

25

Embodiment 110: The detector according to any one of the three preceding embodiments, wherein the illumination source is adapted to generate at least one illumination pattern for illumination of the object, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern or a random point pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern, in particular a rotated hexagonal pattern and/or a displaced hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one fringe pattern; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines.

30

35

40

Embodiment 111: The detector according to the preceding embodiment, wherein the optical sensors are adapted to determine at least one reflection pattern, wherein the evaluation device is adapted to select at least one feature of the reflection pattern and to determine the longitudinal coordinate z of the selected feature of the reflection pattern by evaluating the quotient signal

45

Q.

Embodiment 112: The detector according to any one of the twenty-five preceding embodiments, wherein the detector further comprises at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensors.

5

Embodiment 113: The detector according to the preceding embodiment, wherein the transfer device comprises one or more of: at least one lens, for example, at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one diffractive optical element; at least one Fresnel lens; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

10

15

Embodiment 114: A detector for determining a position of at least one object, the detector having

- at least one first optical sensor having a first light-sensitive area, wherein the first optical sensor is configured to generate at least one first sensor signal in response to an illumination of the first light-sensitive area by a light beam propagating from the object to the detector;
- at least one second optical sensor having:
 - o at least one fluorescent waveguiding sheet forming a second light-sensitive area, wherein the fluorescent waveguiding sheet is oriented towards the object such that at least one light beam propagating from the object towards the detector generates at least one light spot in the second light-sensitive area, wherein the fluorescent waveguiding sheet contains at least one fluorescent material, wherein the fluorescent material is adapted to generate fluorescence light in response to the illumination by the light beam; and
 - o at least one photosensitive element located at at least one edge of the fluorescent waveguiding sheet, capable of detecting fluorescence light guided from the light spot towards the photosensitive element by the fluorescent waveguiding sheet and capable of generating at least one second sensor signal in response to the illumination of the second light-sensitive area by the light beam, wherein the first light-sensitive area is smaller than the second light-sensitive area; and
- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating the first and second sensor signals.

20

25

30

35

Embodiment 115: The detector according to the preceding embodiment, wherein the at least one photosensitive element is located at at least one of: a corner of the fluorescent waveguiding sheet; a straight edge, e.g. a straight rim portion, of the fluorescent waveguiding sheet.

40

Embodiment 116: The detector according to any one of the two preceding embodiments, wherein the at least one photosensitive element is optically coupled to the fluorescent waveguiding sheet by at least one optical coupling element configured for at least partially coupling the fluo-

rescence light guided by the fluorescent waveguiding sheet out of the fluorescent waveguiding sheet.

5 Embodiment 117: The detector according to the preceding embodiment, wherein the optical coupling element is configured for at least partially coupling the fluorescence light coupled out of the fluorescent waveguiding sheet into the photosensitive element.

10 Embodiment 118: The detector according to any one of the two preceding embodiments, wherein the optical coupling element is selected from the group consisting of: a portion of transparent adhesive attaching the photosensitive element to the fluorescent waveguiding sheet; an etched portion within the fluorescent waveguiding sheet; a scratch in the fluorescent waveguiding sheet; a prism.

15 Embodiment 119: The detector according to any one of the five preceding embodiments, wherein the at least one first optical sensor and the at least one photosensitive element of the at least one second optical sensor have essentially identical electrical capacitance.

20 Embodiment 120: The detector according to any one of the six preceding embodiments, wherein the evaluation device is configured for deriving a quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals, wherein the evaluation device is configured for determining the longitudinal coordinate by evaluating the quotient signal Q .

25 Embodiment 121: The detector according to the preceding embodiment, wherein the evaluation device is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate.

30 Embodiment 122: The detector according to the preceding embodiment, wherein the predetermined relationship is one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship.

35 Embodiment 123: The detector according to any one of the two preceding embodiments, wherein the evaluation device comprises at least one data storage device for storing the predetermined relationship.

Embodiment 124: The detector according to any one of the four preceding embodiments, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the quotient signal.

40 Embodiment 125: The detector according to the preceding embodiment, wherein the divider is fully or partially embodied as one or both of a software divider or a hardware divider.

Embodiment 126: The detector according to any one of the twelve preceding embodiments, wherein the first optical sensor is located in front of the second optical sensor, preferably such

that the light beam, in the given order, illuminates the first optical sensor and, afterwards, the second optical sensor.

Embodiment 127: The detector according to any one of the thirteen preceding embodiments, wherein the second optical sensor comprises at least two, preferably at least three and most preferably at least four photosensitive elements located at at least two edges of the fluorescent waveguiding sheet, capable of detecting fluorescence light guided from the light spot towards the photosensitive elements by the fluorescent waveguiding sheet and capable of generating at least one sensor signal each.

Embodiment 128: The detector according to the preceding embodiment, wherein the at least two photosensitive elements are located at one or more of: at least two straight edges, e.g. straight rim portions, of the fluorescent waveguiding sheet, at least two corners of the fluorescent waveguiding sheet, at least one corner of the fluorescent waveguiding sheet and at least one straight edge of the fluorescent waveguiding sheet.

Embodiment 129: The detector according to the preceding embodiment, wherein the evaluation device comprises at least one summing device configured for summing up the sensor signals of the at least two photosensitive elements, thereby forming a sum signal S.

Embodiment 130: The detector according to the preceding embodiment, wherein the sum signal is derived by using the formula $S = \sum_i c_i s_i$, with s_i being the sensor signals, with $i = 1 \dots N$ with N being a positive integer indicating the number of the photosensitive elements or a smaller positive integer, and with c_i being respective calibration coefficients.

Embodiment 131: The detector according to any one of the two preceding embodiments, wherein the evaluation device is configured to determine the at least one longitudinal coordinate z of the object by using at least one predetermined relationship between the first sensor signal, the sum signal S of the second sensor signals and the longitudinal coordinate z.

Embodiment 132: The detector according to any one of the four preceding embodiments, wherein the evaluation device is further configured to determine at least one transversal coordinate x, y of the object by evaluating the sensor signals of the photosensitive elements.

Embodiment 133: The detector according to the preceding embodiment, wherein the evaluation device comprises at least one subtracting device configured to form at least one difference signal D between second sensor signals generated by at least two of the photosensitive elements.

Embodiment 134: The detector according to the preceding embodiment, wherein the second sensor signals comprise at least one second sensor signal s_{21} and at least one second sensor signal s_{22} , wherein the at least one difference signal D is proportional to $a \cdot s_{21} - b \cdot s_{22}$, with a, b being real number coefficients, preferably with $a=1$ and $b=1$.

Embodiment 135: The detector according to the preceding embodiment, wherein the at least one difference signal D is derived according to the formula $D = (a \cdot s_{21} - b \cdot s_{22}) / (a \cdot s_{21} + b \cdot s_{22})$.

Embodiment 136: The detector according to any one of the three preceding embodiments, wherein the subtracting device is configured to form at least one first difference signal D_x from which at least one first transversal coordinate x of the object is derived, wherein the subtracting device is further configured to form at least one second difference signal D_y from which at least one second transversal coordinate y of the object is derived.

Embodiment 137: The detector according to the preceding embodiment, wherein the first difference signal D_x is generated from at least two second sensor signals s_{x1} , s_{x2} of at least two photosensitive elements located at opposing edges, e.g. opposing rim portions and/or corners, of the waveguiding sheet in a first dimension, and wherein the second difference signal D_y is generated from at least two second sensor signals s_{y1} , s_{y2} of at least two photosensitive elements located at opposing edges, e.g. opposing rim portions and/or corners, of the waveguiding sheet in a second dimension.

Embodiment 138: The detector according to the preceding embodiment, wherein the at least one first difference signal D_x is derived according to the formula $D_x = (a \cdot s_{x1} - b \cdot s_{x2}) / (a \cdot s_{x1} + b \cdot s_{x2})$, and wherein the at least one second difference signal D_y is derived according to the formula $D_y = (c \cdot s_{y1} - d \cdot s_{y2}) / (c \cdot s_{y1} + d \cdot s_{y2})$, with a , b , c , d being real number coefficients, preferably with $a=1$, $b=1$, $c=1$ and $d=1$.

Embodiment 139: The detector according to any one of the 11 preceding embodiments, wherein the photosensitive elements comprise at least two photosensitive elements located at opposing edges, e.g. opposing rim portions and/or corners, of the fluorescent waveguiding sheet.

Embodiment 140: The detector according to any one of the 12 preceding embodiments, wherein the photosensitive elements comprise at least one first pair of photosensitive elements located at opposing edges, e.g. opposing rim portions and/or corners, of the fluorescent waveguiding sheet in a first dimension of a coordinate system, wherein the photosensitive elements further comprise at least one second pair of photosensitive elements located at opposing edges, e.g. opposing rim portions and/or corners, of the fluorescent waveguiding sheet in a second dimension of the coordinate system.

Embodiment 141: The detector according to any one of the 27 preceding embodiments, wherein the second sensitive area is a homogeneous sensitive area.

Embodiment 142: The detector according to any one of the 28 preceding embodiments, wherein the second sensitive area has a surface area of at least 5 mm^2 , preferably of at least 10 mm^2 , more preferably of at least 100 mm^2 , more preferably of at least 400 mm^2 .

Embodiment 143: The detector according to any one of the 29 preceding embodiments, wherein the fluorescent waveguiding sheet comprises at least one planar sheet.

Embodiment 144: The detector according to any one of the 30 preceding embodiments, wherein the fluorescent waveguiding sheet has a thickness of 10 μm to 3 mm, preferably a thickness of 100 μm to 1 mm, such as a thickness of 50 μm to 2 mm.

5

Embodiment 145: The detector according to any one of the 31 preceding embodiments, wherein the fluorescent waveguiding sheet is flexible or deformable.

Embodiment 146: The detector according to any one of the 32 preceding embodiments, wherein the fluorescent waveguiding sheet comprises at least one matrix material, wherein the at least one fluorescent material is one or more of mixed into the matrix material, dispersed into the matrix material, chemically bound to the matrix material or dissolved in the matrix material.

10

Embodiment 147: The detector according to the preceding embodiment, wherein the matrix material comprises at least one plastic material.

15

Embodiment 148: The detector according to the preceding embodiment, wherein the plastic material comprises at least one polymer material.

Embodiment 149: The detector according to any one of the two preceding embodiments, wherein the plastic material comprises at least one material selected from the group consisting of: a polycarbonate, a poly(methyl methacrylate), a polystyrene, a polyurethane, a polypropylene, a polyethylene terephthalate, a polyvinylchloride.

20

Embodiment 150: The detector according to any one of the 36 preceding embodiments, wherein the fluorescent material comprises at least one fluorescent dye.

25

Embodiment 151: The detector according to the preceding embodiment, wherein the fluorescent dye comprises at least one organic fluorescent dye.

30

Embodiment 152: The detector according to any one of the two preceding embodiments, wherein the fluorescent dye is selected from the group consisting of: a xanthene derivative, preferably one or more of fluorescein, rhodamine, oregon green, eosin, texas red, or a derivative of any component thereof; a cyanine derivative, preferably one or more of cyanine, indocarbocyanine, oxacarbocyanine, thiocarbocyanine, merocyanine, or a derivative of any component thereof; a squaraine derivative or a ring-substituted squaraine, preferably one or more of Seta, SeTau, and Square dyes, or a derivative of any component thereof; a naphthalene derivative, preferably one or more of a dansyl or a prodan derivative thereof; a coumarin derivative; a oxadiazole derivative, preferably one or more of pyridyloxazole, nitrobenzoxadiazole, benzoxadiazole, or a derivative of any component thereof; an anthracene derivative, preferably one or more of an anthraquinone, DRAQ5, DRAQ7, CyTRAK orange, or a derivative of any component thereof; a pyrene derivative, preferably cascade blue; an oxazine derivative, preferably one or more of nile red, nile blue, cresyl violet, oxazine 170, or a derivative of any component thereof; an acridine derivative, preferably one or more of proflavin, acridine orange, acridine yellow, or a derivative

35

40

of any component thereof; an arylmethine derivative, preferably one or more of auramine, crystal violet, malachite green, or a derivative of any component thereof; a tetrapyrrole derivative, preferably one or more of porphin, phthalocyanine, bilirubin; a rylene dye or any derivative thereof, such as a perylene dye; a naphthalene imide or perylene imide; a naphthoilene benzimidazole dye such as published in WO 2012/168395 A1; or a derivative of any component thereof.

Embodiment 153: The detector according to any one of the 39 preceding embodiments, wherein the at least one photosensitive element comprises at least one elongated photosensitive element extending along at least one segment of an edge of the fluorescent waveguiding sheet.

Embodiment 154: The detector according to any one of the 40 preceding embodiments, wherein the fluorescent waveguiding sheet is a rectangular fluorescent waveguiding sheet, preferably a square fluorescent waveguiding sheet, wherein photosensitive elements are located at each of the four edges, e.g. each of the four rim portions and/or corners, of the fluorescent waveguiding sheet.

Embodiment 155: The detector according to any one of the 41 preceding embodiments, wherein the detector further comprises at least one optical filter element, preferably at least one optical short-pass filter.

Embodiment 156: The detector according to any one of the 42 preceding embodiments, wherein the first and second optical sensors are arranged linearly in one and the same beam path of the detector.

Embodiment 157: The detector according to the preceding embodiment, wherein the first and second optical sensors are arranged concentrically with respect to an optical axis of the detector.

Embodiment 158: The detector according to any one of the 44 preceding embodiments, wherein the first optical sensor is arranged in front of the second optical sensor and is spaced apart from the second optical sensor by no more than five times the square root of a surface area of the first light-sensitive area.

Embodiment 159: The detector according to any one of the 45 preceding embodiments, wherein the first optical sensor is arranged in front of the second optical sensor and is spaced apart from the second optical sensor by no more than 50 mm, preferably by no more than 15 mm.

Embodiment 160: The detector according to any one of the 46 preceding embodiments, wherein the second light-sensitive area is larger by at least a factor of two, more preferably by at least a factor of three and most preferably by at least a factor of five as compared to the first light-sensitive area.

Embodiment 161: The detector according to any one of the 47 preceding embodiments, wherein the first light-sensitive area has a surface area of 1 mm² to 150 mm², more preferably a surface area of 10 mm² to 100 mm².

- 5 Embodiment 162: The detector according to any one of the 48 preceding embodiments, specifically according to the preceding embodiment, wherein the second light-sensitive area has a surface area of 160 mm² to 1000 mm², more preferably a surface area of 200 mm² to 600 mm².

- 10 Embodiment 163: The detector according to any one of the 49 preceding embodiments, wherein the first and second optical sensor each have, at least within a range of measurement, a linear signal characteristic such that the respective first and second sensor signals are dependent on the total power of illumination of the respective optical sensor and are independent from a diameter of a light spot of the illumination.

- 15 Embodiment 164: The detector according to any one of the 50 preceding embodiments, wherein the first optical sensor is a semiconductor sensor, preferably an inorganic semiconductor sensor, more preferably a photodiode and most preferably a silicon photodiode.

- 20 Embodiment 165: The detector according to any one of the 51 preceding embodiments, wherein the first optical sensor is a uniform sensor having a single light-sensitive area.

Embodiment 166: The detector according to any one of the 52 preceding embodiments, wherein the detector further comprises an illumination source for illuminating the object.

- 25 Embodiment 167: The detector according to the preceding embodiment, wherein the illumination source is configured for generating an illuminating light beam for illuminating the object, wherein the detector is configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector.

- 30 Embodiment 168: The detector according to the preceding embodiment, wherein the detector comprises at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

- 35 Embodiment 169: The detector according to any one of the 55 preceding embodiments, wherein the detector further comprises at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensors.

- 40 Embodiment 170: The detector according to the preceding embodiment, wherein the transfer device comprises one or more of: at least one lens, at least one focus-tunable lens, at least one spheric lens, at least one aspheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

Embodiment 171: The detector according to any one of the 57 preceding embodiments, wherein the first light-sensitive area, in a direction of propagation of the light beam, overlaps with the second light-sensitive area.

- 5 Embodiment 172: A detector for determining a position of at least one object, the detector comprising:
- at least one angle dependent optical element adapted to generate at least one transmission light beam having at least one beam profile depending on an angle of incidence of an incident light beam propagating from the object towards the detector and illuminating the angle dependent optical element;
 - 10 - at least two optical sensors, wherein each optical sensor has at least one light sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by the light beam generated by the angle dependent optical element;
 - 15 - at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by evaluating a quotient signal Q from the sensor signals.

Embodiment 173: The detector according to the preceding embodiment, wherein the angle dependent optical element comprises at least one optical element selected from the group consisting of: at least one optical fiber, in particular at least one multifurcated optical fiber, in particular at least one bifurcated optical fiber; at least one diffractive optical element; at least one angle dependent reflective element, at least one diffractive grating element, in particular a blaze grating element; at least one aperture stop; at least one lens array, in particular at least one microlens array; at least one optical filter; at least one polarization filter; at least one bandpass filter;

20 at least one liquid crystal filter, in particular a liquid crystal tunable filter; at least one short-pass filter; at least one long-pass filter; at least one notch filter; at least one interference filter; at least one transmission grating; at least one nonlinear optical element, in particular one birefringent optical element.

30 Embodiment 174: The detector according to any one of the two preceding embodiments, wherein the detector comprises at least one transfer device, wherein the transfer device has at least one focal length in response to at least one incident light beam propagating from the object to the detector.

35 Embodiment 175: The detector according to any one of the three preceding embodiments, wherein the detector further comprises an illumination source for illuminating the object.

Embodiment 176: The detector according to the preceding embodiment, wherein the illumination source is adapted to illuminate the object through the angle dependent optical element.

40

Embodiment 177: The detector according to any one of the two preceding embodiments, wherein the illumination source and the angle dependent optical element are arranged in the direction

of propagation of the light beam traveling from the object to the detector behind the transfer device.

Embodiment 178: The detector according to any one of the three preceding embodiments, wherein a distance perpendicular to an optical axis of the detector between the illumination source and the optical sensors is small.

Embodiment 179: The detector according to the preceding embodiment, wherein the distance perpendicular to the optical axis of the detector between the illumination source and the optical sensors is less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m.

Embodiment 180: The detector according to any one of the two preceding embodiments, wherein the angle dependent optical element is an optical fiber, wherein the illumination source is guided through the optical fiber, wherein the illumination source is adapted to generate at least one illumination beam, wherein the illumination beam exits the optical fiber behind the transfer device within a baseline that is smaller than a radius of the transfer device, wherein the optical fiber guiding the illumination beam may be attached to the transfer device to reduce reflections at interfaces with larger differences in refractive index.

Embodiment 181: The detector according to the preceding embodiment, wherein the optical fiber is attached to the transfer device by one or more of a polymer, a glue or other means for attachment.

Embodiment 182: The detector according to any one of the four preceding embodiments, wherein the distance perpendicular to the optical axis of the detector between the illumination source and the optical sensors is less than the radius of the transfer device.

Embodiment 183: The detector according to any one of the eleven preceding embodiments, wherein the evaluation device is configured for deriving the quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

Embodiment 184: The detector according to the preceding embodiment, wherein the evaluation device is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate for determining the longitudinal coordinate.

Embodiment 185: The detector according to any one of the thirteen preceding embodiments, wherein the evaluation device is configured for deriving the quotient signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, $A1$ and $A2$ are areas of the beam profile at a sensor position of the optical sensors, and $E(x,y,z_0)$ denotes the beam profile given at the object distance z_0 .

- 5 Embodiment 186: The detector according to any one of the fourteen preceding embodiments, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the quotient signal.

- 10 Embodiment 187: The detector according to any one of the fifteen preceding embodiments, wherein the optical sensors are positioned off focus.

- 15 Embodiment 188: The detector according to any one of the sixteen preceding embodiments, wherein each of the sensor signals comprises at least one information of at least one area of the beam profile of the beam profile of the light beam generated by the angle dependent optical element.

- 20 Embodiment 189: The detector according to the preceding embodiment, wherein the beam profile is selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles.

- 25 Embodiment 190: The detector according to any one of the two preceding embodiments, wherein the light-sensitive areas are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.

- 30 Embodiment 191: The detector according to the preceding embodiment, wherein the evaluation device is configured to determine the first area of the beam profile and the second area of the beam profile.

- 35 Embodiment 192: The detector according to any one of the four preceding embodiments, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile.

- 40 Embodiment 193: The detector according to any one of the twenty preceding embodiments, wherein the edge information comprises information relating to a number of photons in the first area of the beam profile and the center information comprises information relating to a number of photons in the second area of the beam profile.

- Embodiment 194: The detector according to any one of the two preceding embodiments, wherein the light beam propagating from the object to the detector illuminates the optical sensors with at least one line pattern, wherein $A1$ corresponds to an area with a full line width of the line pat-

tern on the optical sensors, wherein A2 is a central area of the line pattern on the optical sensors.

Embodiment 195: The detector according to any one of the four preceding embodiments, wherein the light beam propagating from the object to the detector illuminates the optical sensors with at least one point pattern, wherein A1 corresponds to an area with a full radius of a point of the point pattern on the optical sensors, wherein A2 is a central area of the point in the point pattern on the optical sensors.

Embodiment 196: The detector according to any one of the two the preceding embodiments, wherein the evaluation device is configured to derive the quotient signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center in-formation.

Embodiment 197: The detector according to any one of the 23 preceding embodiments, wherein the detector has at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor is configured to generate at least one sensor signal in response to an illumination of the light-sensitive area by the light beam generated by the angle dependent optical element.

Embodiment 198: The detector according to the preceding embodiment, wherein the evaluation device is configured for evaluating the sensor signals, by

- a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
- b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;
- c) determining at least one combined signal by combining the center signal and the sum signal; and
- d) determining at least one longitudinal coordinate z of the object by evaluating the combined signal.

Embodiment 199: The detector according to the preceding embodiment, wherein the center signal is selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor

signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

- 5 Embodiment 200: The detector according to any one of the two preceding embodiments, wherein the sum signal is selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for
10 sensor signals from those optical sensors contributing to the center signal; an integral of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a
15 sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal.
- 20 Embodiment 201: The detector according to any one of the three preceding embodiments, wherein the combined signal is the quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a
25 quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal.

Embodiment 202: The detector according to any one of the 27 preceding embodiments, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different spatial offsets,
30 wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by the light beam generated by the angle dependent optical element.

35 Embodiment 204: The detector according to the preceding embodiment, wherein the optical sensors are part of a sensor array, wherein a geometrical center of the sensor array is offset from the optical axis.

Embodiment 205: The detector according to the preceding embodiment, wherein the sensor
40 array is movable relative to the optical axis.

Embodiment 206: The detector according to the preceding embodiment, wherein the evaluation device is configured for, firstly, determining the transversal position of a light spot generated by

the light beam on the sensor array by using the sensor signals and for, secondly, moving the sensor array relative to the optical axis until the light spot is off-centered.

5 Embodiment 207: The detector according to any one of the four preceding embodiments, wherein the optical sensors are partial diodes of a bi-cell or quadrant diode, with a geometrical center of the quadrant diode being off-centered from the optical axis of the detector.

10 Embodiment 208: A detector system for determining a position of at least one object, the detector system comprising at least one detector according to any one of the preceding embodiments, the detector system further comprising at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object.

15 Embodiment 209: A human-machine interface for exchanging at least one item of information between a user and a machine, wherein the human-machine interface comprises at least one detector system according to the preceding embodiment, wherein the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user and held by the user, wherein the human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to
20 assign to the position at least one item of information.

Embodiment 210: An entertainment device for carrying out at least one entertainment function, wherein the entertainment device comprises at least one human-machine interface according to the preceding embodiment, wherein the entertainment device is designed to enable at least one
25 item of information to be input by a player by means of the human-machine interface, wherein the entertainment device is designed to vary the entertainment function in accordance with the information.

30 Embodiment 211: A tracking system for tracking a position of at least one movable object, the tracking system comprising at least one detector system according to any one of the preceding embodiments referring to a detector system, the tracking system further comprising at least one track controller, wherein the track controller is adapted to track a series of positions of the object at specific points in time.

35 Embodiment 212: A scanning system for determining a depth profile of a scenery, the scanning system comprising at least one detector according to any of the preceding embodiments referring to a detector, the scanning system further comprising at least one illumination source adapted to scan the scenery with at least one light beam.

40 Embodiment 213: A camera for imaging at least one object, the camera comprising at least one detector according to any one of the preceding embodiments referring to a detector.

Embodiment 214: An inertial measurement unit for use in an electronic device, wherein the inertial measurement unit is adapted to receive data determined by at least one detector according to any one of the preceding embodiment referring to a detector, wherein the inertial measurement unit further is adapted to receive data determined by at least one further sensor selected from the group consisting of: a wheel speed sensor, a turn rate sensor, an inclination sensor, an orientation sensor, a motion sensor, a magneto hydro dynamic sensor, a force sensor, an angular sensor, an angular rate sensor, a magnetic field sensor, a magnetometer, an accelerometer; a gyroscope, wherein the inertial measurement unit is adapted to determine by evaluating the data from the detector and the at least one further sensor at least one property of the electronic device selected from the group consisting of: position in space, relative or absolute motion, rotation, acceleration, orientation, angle position, inclination, turn rate, speed.

Embodiment 215: A readout device for optical storage media, the readout device comprising at least one detector according to any one of the preceding embodiments referring to a detector.

Embodiment 216: A method for determining a position of at least one object by using at least one detector, the method comprising the following steps:

- providing at least two optical sensors, each optical sensor having a light-sensitive area, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by the light beam, wherein the detector has at least one transfer device, wherein the transfer device has at least one focal length in response to the light beam propagating from the object to the detector;
- illuminating each of the light-sensitive areas of the at least two optical sensors of the detector with a light beam propagating from the object to the detector, wherein, thereby, each of the light-sensitive areas generates at least one sensor signal; and
- evaluating the sensor signals, thereby, determining at least one longitudinal coordinate z of the object, wherein the evaluating comprises deriving a quotient signal Q of the sensor signals.

Embodiment 217: The method according to the preceding embodiment, wherein the longitudinal coordinate z of the object is determined in at least one measurement range independent from the object size in an object plane.

Embodiment 218: The method according to the preceding embodiment, wherein the deriving of the quotient signal Q comprises one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

Embodiment 219: The method according to any one of the preceding embodiments referring to a method, wherein the method comprises adjusting the measurement range by adjusting on one or more parameters selected from the group consisting of: a longitudinal distance from the object to the transfer device z_0 ; the focal length of the transfer device f ; a diameter of an exit pupil of the transfer device E_x ; a longitudinal distance from the transfer device to the light sensitive

area z_s , a distance from the transfer device to an image of the object z_i ; an object size O_{size} of the object in the object plane.

Embodiment 220: The method according to any one of the preceding embodiments referring to a method, wherein the transfer device has an optical axis, wherein the transfer device constitutes a coordinate system, wherein a longitudinal coordinate l is a coordinate along the optical axis and wherein d is a spatial offset from the optical axis, wherein the method comprises arranging the optical sensors such that the light-sensitive areas of the optical sensors differ in at least one of: their longitudinal coordinate, their spatial offset, or their surface areas.

Embodiment 221: The method according to any one of the preceding embodiments referring to a method, wherein each of the sensor signals comprises at least one information of at least one beam profile of the light beam, wherein the beam profile is selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles, wherein the light-sensitive regions are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.

Embodiment 222: The method according to the preceding embodiment, wherein the evaluating comprises determining the first area of the beam profile and the second area of the beam profile.

Embodiment 223: The method according to any one of the two preceding embodiments, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile, wherein the edge information comprises an information relating to a number of photons in the first area of the beam profile and the center information comprises an information relating to a number of photons in the second area of the beam profile, wherein the evaluating comprises deriving the quotient signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information.

Embodiment 224: A method for determining a position of at least one object by using at least one detector, the method comprising the following steps:

- illuminating at least one first light-sensitive area of at least one first optical sensor of the detector with a light beam propagating from the object to the detector and, thereby, generating at least one first sensor signal;
- illuminating at least one second light-sensitive area of at least one second optical sensor of the detector with the light beam and, thereby, generating at least one sec-

ond sensor signal, wherein the first light-sensitive area is smaller than the second light-sensitive area; and

- evaluating the first and second sensor signals, thereby determining at least one longitudinal coordinate z of the object.

5

Embodiment 225: The method according to the preceding embodiment, wherein the evaluating the first and second sensor signal comprises deriving a quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals, and wherein the determining the longitudinal coordinate comprises evaluating the quotient signal Q .

10

Embodiment 226: A method for determining a position of at least one object by using at least one detector, the method comprising the following steps:

- illuminating at least one sensor element of the detector with at least one light beam propagating from the object to the detector, the detector having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor generates at least one sensor signal in response to the illumination;

15

- evaluating the sensor signals, by

- a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;

20

- b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;

- c) determining at least one combined signal by combining the center signal and the sum signal; and

25

- d) determining at least one longitudinal coordinate z of the object by evaluating the combined signal.

Embodiment 227: The method according to the preceding embodiment, wherein the combined signal is a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal.

35

Embodiment 228: The method according to the preceding embodiment, wherein determining the longitudinal coordinate comprises evaluating the quotient signal Q , wherein evaluating the quotient signal comprises using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate for determining the longitudinal coordinate.

40

Embodiment 229: The method according to any one of the three preceding method embodiments, wherein the method comprises using the detector according to any one of the preceding embodiments referring to a detector.

Embodiment 230: A method for determining a position of at least one object by using at least one detector, the method comprising the following steps:

- providing at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different separations, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by a light beam;
- illuminating the at least two light-sensitive areas of the at least two optical sensors of the detector with a light beam propagating from the object to the detector and, thereby, generating at least two sensor signals; and
- evaluating the sensor signals by combining the at least two sensor signals, thereby determining at least one longitudinal coordinate z of the object.

Embodiment 231: The method according to the preceding embodiment, wherein evaluating of the sensor signals comprises deriving a quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals, and wherein the determining of the longitudinal coordinate comprises evaluating the quotient signal Q .

Embodiment 232: A method for determining a position of at least one object by using at least one detector, the method comprising the following steps:

- providing at least one angle dependent optical element and generating at least one light beam having at least one beam profile depending on an angle of incidence;
- providing at least two optical sensors, wherein each optical sensor has at least one light sensitive area, wherein each optical sensor is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by the light beam generated by the angle dependent optical element;
- illuminating each of the light-sensitive areas of the at least two optical sensors of the detector with the light beam generated by the angle dependent optical element, wherein, thereby, each of the light-sensitive areas generates at least one sensor signal; and
- evaluating the sensor signals, thereby, determining at least one longitudinal coordinate z of the object, wherein the evaluating comprises deriving a combined signal Q of the sensor signals.

Embodiment 233: The method according to the preceding embodiment, wherein the deriving of the combined signal Q comprises one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

Embodiment 234: A use of the detector according to any one of the preceding embodiments relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; an optical data storage appli-

cation; a security application; a surveillance application; a safety application; a human-machine interface application; a tracking application; a photography application; a logistics application; a machine vision application; a robotics application; a quality control application; a manufacturing application; a use in combination with optical data storage and readout.

5

Brief description of the figures

Further optional details and features of the invention are evident from the description of preferred exemplary embodiments which follows in conjunction with the dependent claims. In this
10 context, the particular features may be implemented in an isolated fashion or in combination with other features. The invention is not restricted to the exemplary embodiments. The exemplary embodiments are shown schematically in the figures. Identical reference numerals in the individual figures refer to identical elements or elements with identical function, or elements which correspond to one another with regard to their functions.

Detailed description of the embodiments:

- 25 In Fig. 1, a schematic view of a first embodiment of a detector 110 for determining a position of at least one object 112 is depicted. The detector 110 comprises at least two optical sensors 113, for example a first optical sensor 118 and a second optical sensor 120, each having at least one light-sensitive area 121. In this case, the object 112 comprises a beacon device 114, from which a light beam 116 propagates towards the first optical sensor 118 and the second
- 30 optical sensor 120. The first optical sensor 118 may comprise a first light-sensitive area 122, and the second optical sensor 120 may comprise a second light-sensitive area 124. The light beam 116, as an example, may propagate along an optical axis 126 of the detector 110. Other embodiments, however, are feasible. The optical detector 110, further, comprises at least one transfer device 128, such as at least one lens or a lens system, specifically for beam shaping.
- 35 The transfer device 128 has at least one focal length in response to the incident light beam 116 propagating from the object 112 to the detector 110. The transfer device 128 has an optical axis 129, wherein the transfer device 128 and the optical detector preferably may have a common optical axis. The transfer device 128 constitutes a coordinate system. A direction parallel or anti-parallel to the optical axis 126, 129 may be defined as a longitudinal direction, whereas direc-
- 40 tions perpendicular to the optical axis 126, 129 may be defined as transversal directions, wherein a longitudinal coordinate l is a coordinate along the optical axis 126, 129 and wherein d is a spatial offset from the optical axis 126, 129. Consequently, the light beam 116 is focused, such as in one or more focal points 130, and a beam width of the light beam 116 may depend on a

longitudinal coordinate z of the object 112, such as on a distance between the detector 110 and the beacon device 114 and/or the object 112. The optical sensors 118, 120 may be positioned off focus. For details of this beam width dependency on the longitudinal coordinate, reference may be made to one or more of WO 2012/110924 A1 and/or WO 2014/097181 A1.

5

In this first preferred embodiment the optical sensors 118, 120 may be arranged such that the light-sensitive areas 122, 124 differ in their longitudinal coordinate and/or their surface areas and/or their surface shapes. As can be seen in Fig. 1, the first optical sensor 118 is a small optical sensor, whereas the second optical sensor 120 is a large optical sensor. Thus, the width of the light beam 116 fully covers the first light-sensitive area 122, whereas, on the second light-sensitive area 124, a light spot is generated which is smaller than the second light-sensitive area 124, such that the light spot is fully located within the second light-sensitive area 124. As an example, the first light-sensitive area 122 may have a surface area of 1 mm^2 to 100 mm^2 , whereas the second light-sensitive area 124 may have a surface area of 50 to 600 mm^2 . Other embodiments, however, are feasible.

10

15

The first optical sensor 118, in response to the illumination by the light beam 116, may generate a first sensor signal s_1 , whereas the second optical sensor 120 may generate a second sensor signal s_2 . Preferably, the optical sensors 118, 120 are linear optical sensors, i.e. the sensor signals s_1 and s_2 each are solely dependent on the total power of the light beam 116 or of the portion of the light beam 116 illuminating their respective light-sensitive areas 122, 124, whereas these sensor signals s_1 and s_2 are independent from the actual size of the light spot of illumination. In other words, preferably, the optical sensors 118, 120 do not exhibit the above-described FiP effect.

25

The sensor signals s_1 and s_2 are provided to an evaluation device 132 of the detector 110. The evaluation device 132, as symbolically shown in Fig. 1, is embodied to derive a quotient signal Q , as explained above. From the quotient signal Q , derived by dividing the sensor signals s_1 and s_2 or multiples or linear combinations thereof, may be used for deriving at least one item of information on a longitudinal coordinate z of the object 112 and/or the beacon device 114, from which the light beam 116 propagates towards the detector 110. For further details of this evaluation, reference is made to Fig. 3 and 4 below.

30

The detector 110, in combination with the at least one beacon device 114, may be referred to as a detector system 134, as will be explained in further detail below with reference to Fig. 5.

35

In Fig. 2, a modification of the embodiment of Fig. 1 is shown, which forms an alternative detector 110. The alternative embodiment of the detector 110 widely corresponds to the embodiment shown in Fig. 1. Instead of using an active light source, i.e. a beacon device 114 with light-emitting properties for generating the light beam 116, however, the detector 110 comprises at least one illumination source 136. The illumination source 136, as an example, may comprise a laser, whereas, in Fig. 1, as an example, the beacon device 114 may comprise a light-emitting diode (LED). The illumination source 136 may be configured for generating at least one illumi-

40

nation light beam 138 for illuminating the object 112. The illumination light beam 138 is fully or partially reflected by the object 112 and travels back towards the detector 110, thereby forming the light beam 116.

- 5 As shown in Fig. 2, as an example, the illumination light beam 138 may be parallel to the optical axis 126 of the detector 110. Other embodiments, i.e. off-axis illumination and/or illumination at an angle, are feasible, too. In order to provide an on-axis illumination, as shown in Fig. 2, as an example, one or more reflective elements 140 may be used, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms.

10

Apart from these modifications, the setup of the embodiment in Fig. 2 corresponds to the setup in Fig. 1. Thus, again, an evaluation device 132 may be used, having, e.g., at least one divider 142 for forming the quotient signal Q , and, as an example, at least one position evaluation device 144, for deriving the at least one longitudinal coordinate z from the quotient signal Q . It shall be noted that the evaluation device 132 may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 142, 144 may be embodied by appropriate software components.

15

20

It shall further be noted that the embodiments shown in Fig. 1 and 2 simply provide embodiments for determining the longitudinal coordinate z of the object 112. It is also feasible, however, to modify the setups of Fig. 1 and 2 to provide additional information on a transversal coordinate of the object 112 and/or of parts thereof. As an example, e.g. in between the transfer device 128 and the optical sensors 118, 120, one or more parts of the light beam 116 may be branched off, and may be guided to a position-sensitive device such as one or more CCD and/or CMOS pixelated sensors and/or quadrant detectors and/or other position sensitive devices, which, from a transversal position of a light spot generated thereon, may derive a transversal coordinate of the object 112 and/or of parts thereof. The transversal coordinate may be used to verify and/or enhance the quality of the distance information. For further details, as an example, reference may be made to one or more of the above-mentioned prior art documents which provide for potential solutions of transversal sensors.

25

30

35

40

In Fig. 3 and 4 typical quotient signals Q are depicted, as a function of the longitudinal coordinate z of an object 112 in a test setup. Therein, a simple quotient s_1/s_2 is shown, for an exemplary setup of the detector 110. Fig. 3 and 4, each, show a bundle of experiments which are not resolved in these figures. Thus, in Fig. 3, various curves are given for the setup shown in Fig. 1, with an active beacon device 114 having an LED. The current of the LED target of the beacon device 114, in this experiment, is changed from 1000 mA to 25 mA. Basically, no difference in the quotient signal, as a function of the longitudinal coordinate z (given in mm) can be detected over the spatial measurement range of 250 mm to 2,250 mm. The experiment clearly shows that the setup of the detector 110 according to the present invention is independent from the total power of the light beam 116. Thus, no additional information on the total power of the light beam, and, thus, no additional illumination on the luminance is required in order to derive the

longitudinal coordinate. Thus, as shown in Fig. 3, as an example, a unique relationship between a quotient signal Q^* as measured in an experiment and a longitudinal coordinate z^* exists.

Thus, the curves as shown in Fig. 3, as an example, may be used as calibration curves for indicating a unique and predetermined or determinable relationship between the quotient signal Q and the longitudinal coordinate. The curves as shown in Fig. 3, as an example, may be stored in a data storage and/or in a lookup table. The calibration curves Q may simply be determined by calibration experiments. It is also feasible, however, to derive these curves by one or more of modelling, analytically, semi-empirically and empirically.

The experiment shown in Fig. 3 clearly demonstrates that the setup of the detector 110 according to the present invention provides a large range of measurement, both in terms of space (e.g. a measurement range from 270 to 2,250 mm) and in terms of brightness or total power of the light beam 116. In Fig. 4, an additional experiment is shown which demonstrates that the setup is widely independent from the target size, i.e. the lateral diameter of the beacon device 114. For this experiment, again, an LED beacon device 114 was used, similar to the setup shown in Fig. 1, wherein the size of the target, i.e. the visible part of the LED, was changed by using a diffuser and an adjustable aperture. Thereby, the aperture or the size of the target was varied from 1 mm to 25 mm in diameter. Without resolving the curves shown in Fig. 4 in detail, it is clearly visible that the quotient signal Q , again, is widely independent from the target size, in between a target size of 1 mm to 25 mm. Thus, again, a unique relationship between the quotient signal Q and the longitudinal coordinate z can be derived, for various target sizes, which may be used for evaluation.

The results shown in Fig. 3 and 4 were derived experimentally, by varying the named parameters and by measuring appropriate signals. The results, however, may also be derived analytically, semi-analytically or by modelling. Comparable results were obtained.

Fig. 5 shows, in a highly schematic illustration, an exemplary embodiment of a detector 110, e.g. according to the embodiments shown in Fig. 1 or 2. The detector 110 specifically may be embodied as a camera 146 and/or may be part of a camera 146. The camera 146 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible.

Fig. 5 further shows an embodiment of a detector system 134, which, besides the at least one detector 110, comprises one or more beacon devices 114, which, in this example, may be attached and/or integrated into an object 112, the position of which shall be detected by using the detector 110. Fig. 5 further shows an exemplary embodiment of a human-machine interface 148, which comprises the at least one detector system 134 and, further, an entertainment device 150, which comprises the human-machine interface 148. The figure further shows an embodiment of a tracking system 152 for tracking a position of the object 112, which comprises the detector system 134. The components of the devices and systems shall be explained in further detail below.

Fig. 5 further shows an exemplary embodiment of a scanning system 154 for scanning a scenery comprising the object 112, such as for scanning the object 112 and/or for determining at least one position of the at least one object 112. The scanning system 154 comprises the at least one detector 110, and, further, optionally, the at least one illumination source 136 as well as, optionally, at least one further illumination source 136. The illumination source 136, generally, is configured to emit at least one illumination light beam 138, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 114 and/or on a surface of the object 112. The scanning system 154 may be designed to generate a profile of the scenery including the object 112 and/or a profile of the object 112, and/or may be designed to generate at least one item of information about the distance between the at least one dot and the scanning system 154, specifically the detector 110, by using the at least one detector 110.

As outlined above, an exemplary embodiment of the detector 110 which may be used in the setup of Fig. 5 is shown in Fig. 1 and 2. Thus, the detector 110, besides the optical sensors 118, 120, comprises at least one evaluation device 132, having e.g. the at least one divider 142 and/or the at least one position evaluation device 144, as symbolically depicted in Fig. 5. The components of the evaluation device 132 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 110. Besides the possibility of fully or partially combining two or more components, one or more of the optical sensors 118, 120 and one or more of the components of the evaluation device 132 may be interconnected by one or more connectors 156 and/or by one or more interfaces, as symbolically depicted in Fig. 5. Further, the one or more connectors 156 may comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 156, the evaluation device 132 may fully or partially be integrated into one or both of the optical sensors 118, 120 and/or into a housing 158 of the detector 110. Additionally or alternatively, the evaluation device 132 may fully or partially be designed as a separate device.

In this exemplary embodiment, the object 112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 160, the position of which may be manipulated by a user 162. As an example, the object 112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 112 are possible. Further, the user 162 himself or herself may be considered as the object 112, the position of which shall be detected.

As outlined above, the detector 110 comprises at least the optical sensors 118, 120. The optical sensors 118, 120 may be located inside the housing 158 of the detector 110. Further, the at least one transfer device 128 is comprised, such as one or more optical systems, preferably comprising one or more lenses.

An opening 164 inside the housing 158, which, preferably, is located concentrically with regard to the optical axis 126 of the detector 110, preferably defines a direction of view 166 of the detector 110. A coordinate system 168 may be defined, in which a direction parallel or anti-parallel to the optical axis 126 may be defined as a longitudinal direction, whereas directions perpendicular to the optical axis 126 may be defined as transversal directions. In the coordinate system 128, symbolically depicted in Fig. 5, a longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other types of coordinate systems 168 are feasible, such as non-Cartesian coordinate systems.

The detector 110 may comprise the optical sensors 118, 120 as well as, optionally, further optical sensors. The optical sensors 118, 120 preferably are located in one and the same beam path, one behind the other, such that the first optical sensor 118 covers a portion of the second optical sensor 120. Alternatively, however, a branched beam path may be possible, with additional optical sensors in one or more additional beam paths, such as by branching off a beam path for at least one transversal detector or transversal sensor for determining transversal coordinates of the object 112 and/or of parts thereof. Alternatively, however, the optical sensors 118, 120 may be located at the same longitudinal coordinate.

One or more light beams 116 are propagating from the object 112 and/or from one or more of the beacon devices 114, towards the detector 110. The detector 110 is configured for determining a position of the at least one object 112. For this purpose, as explained above in the context of Fig. 1 to 4, the evaluation device 132 is configured to evaluate sensor signals provided by the optical sensors 118, 120. The detector 110 is adapted to determine a position of the object 112, and the optical sensors 118, 120 are adapted to detect the light beam 116 propagating from the object 112 towards the detector 110, specifically from one or more of the beacon devices 114. In case no illumination source 136 is used, the beacon devices 114 and/or at least one of these beacon devices 114 may be or may comprise active beacon devices with an integrated illumination source such as a light-emitting diode. In case the illumination source 136 is used, the beacon devices 114 do not necessarily have to be active beacon devices. Contrarily, a reflective surface of the object 112 may be used, such as integrated reflected beacon devices 114 having at least one reflective surface such as a mirror, retro reflector, reflective film, or the like. The light beam 116, directly and/or after being modified by the transfer device 128, such as being focused by one or more lenses, illuminates the light-sensitive areas 122, 124 of the optical sensors 118, 120. For details of the evaluation, reference may be made to Fig. 1 to 4 above.

As outlined above, the determination of the position of the object 112 and/or a part thereof by using the detector 110 may be used for providing a human-machine interface 148, in order to provide at least one item of information to a machine 170. In the embodiments schematically depicted in Fig. 5, the machine 170 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 132 may even be fully or partially integrated into the machine 170, such as into the computer.

As outlined above, Fig. 5 also depicts an example of a tracking system 152, configured for tracking the position of the at least one object 112 and/or of parts thereof. The tracking system 152 comprises the detector 110 and at least one track controller 172. The track controller 172 may be adapted to track a series of positions of the object 112 at specific points in time. The track controller 172 may be an independent device and/or may be fully or partially integrated into the machine 170, specifically the computer, as indicated in Fig. 5 and/or into the evaluation device 132.

Similarly, as outlined above, the human-machine interface 148 may form part of an entertainment device 150. The machine 170, specifically the computer, may also form part of the entertainment device 150. Thus, by means of the user 162 functioning as the object 112 and/or by means of the user 162 handling a control device 160 functioning as the object 112, the user 162 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer game.

In Figure 6, a schematic view of a further embodiment of the detector 110 for determining a position of at least one object 112 is depicted. In this case, the object 112 comprises the at least one beacon device 114, from which the light beam 116 propagates towards at least one sensor element 115. The sensor element 115 comprises a matrix 117 of optical sensors 113, each optical sensor 113 having at least one light-sensitive area 121 facing the object 112. In this second preferred embodiment the optical sensors 118, 120 may be arranged such that the light-sensitive areas of the optical sensors 113 differ in spatial offset and/or surface areas. The light beam 116, as an example, may propagate along the optical axis 126 of the detector 110. Other embodiments, however, are feasible. The optical detector 110 comprises the at least one transfer device 128, such as at least one lens and/or at least one lens system, specifically for beam shaping. Consequently, the light beam 116 may be focused, such as in one or more focal points 130, and a beam width of the light beam 116 may depend on the longitudinal coordinate z of the object 112, such as on the distance between the detector 110 and the beacon device 114 and/or the object 112. The transfer device 128 constitutes the optical axis 129, wherein the transfer device 128 and the optical detector preferably may have a common optical axis. Consequently, the light beam 116 is focused, such as in one or more focal points 130, and a beam width of the light beam 116 may depend on a longitudinal coordinate z of the object 112, such as on a distance between the detector 110 and the beacon device 114 and/or the object 112. The optical sensors 118, 120 are positioned off focus. For details of this beam width dependency on the longitudinal coordinate, reference may be made to one or more of WO 2012/110924 A1 and/or WO 2014/097181 A1.

As can be seen in Figure 6, the light beam 116 generates a light spot 131 on the matrix 117. In Figure 8, an exemplary view of the light spot 131 on the matrix 117 is shown. As can be seen, in this exemplary embodiment, the matrix 117 specifically may be a rectangular matrix, with rows numbered by "i", from 1 to n , and with columns, denoted by "j", from 1 to m , with n , m being integers. The center of the light spot 131, in this exemplary embodiment, is located in the sensor

element denoted by i^* , j^* . The optical sensors 113 may provide sensor signals s_{ij} to an evaluation device 132 which, out of the sensor signals, determines at least one center signal, denoted symbolically by $s_{i^*j^*}$. As outlined in further detail above, for generating the center signal, the evaluation device 132 may comprise at least one center detector 133. As an example, the center detector 133 simply may determine the maximum sensor signal out of the plurality of sensor signals generated by the optical sensors 113. Alternative methods are feasible. Thus, as an example, instead of determining a single maximum optical sensor signal, a plurality of sensor signals may be used for generating the center signal. Thus, as an example, neighboring optical sensors which are adjacent to the optical sensor i^* , j^* may contribute to the center signal, such as optical sensors with the coordinates $i^*-1, \dots, i^*+1$ and $j^*-1, \dots, j^*+1$. These coordinates, in the simple exemplary embodiment, may form a square around the optical sensor i^* , j^* . Instead of a square having a side length of 3, as in this embodiment, other environments around the optical sensor having the highest sensor signal may be used such as to optimize the signal to noise ratio of the detector signal and or of the distance information. Further, additionally or alternatively, the center signal may be generated by adding up and/or averaging over sensor signals within a certain range from the maximum sensor signal which may for example be beneficial to the measurement precision concerning noise such as pixel noise. Further, additionally or alternatively, for the determination of the center signal or sum signal, image processing techniques such as sub-pixel processing, interpolation, normalization or the like may be employed. Other alternatives are feasible. The evaluation device 132 may be adapted to determine the center signal by integrating of the plurality of sensor signals, for example the plurality of optical sensors around the optical sensor having the highest sensor signal. For example, the beam profile may be a trapezoid beam profile and the evaluation device 132 may be adapted to determine an integral of the trapezoid, in particular of a plateau of the trapezoid. Further, when trapezoid beam profiles may be assumed, the evaluation device 132 may be adopted to determine the edge and center signals by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations. Additionally or alternatively, the evaluation device 132 may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized for example by replacing the area integrals in the quotient signal Q by a line integrals along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or cuts may result in an improved distance information.

Further, the evaluation device 132 is configured for determining at least one sum signal out of the sensor signals of the matrix 117. For this purpose, the evaluation device 132 may comprise at least one summing device 135. The summing device 135 may be configured for adding up, integrating or averaging over the sensor signals of the entire matrix 117, of a region of interest within the matrix 117, each option with or without the optical sensors from which the center signal is generated. Thus, in the exemplary embodiment shown in Figure 8, the summing device 135 is simply configured for summing over the sensor signals s_{ij} of the entire matrix 117, except for the center optical detector with the coordinates i^* , j^* . Other options, however, are feasible.

The evaluation device 132 may be adapted to determine the sum signal by integrating of signals of the entire matrix 117, of the region of interest within the matrix 117. For example, the beam profile may be a trapezoid beam profile and the evaluation device 132 may be adapted to determine an integral of the entire trapezoid.

5

The evaluation device 132 may be adapted to determine at least one region of interest within the matrix, such as one or more pixels illuminated by the light beam which are used for determination of the longitudinal coordinate of the object. For example, the evaluation device may be adapted to perform at least one filtering, for example at least one object recognition method.

10 The region of interest may be determined manually by a user or maybe determined automatically, such as by recognizing an object within an image generated by the optical sensors.

The evaluation device 132 further is configured for forming at least one combined signal out of the center signal and the sum signal. For this purpose, the evaluation device 132, as an example, may comprise at least one combining device 137, such as at least one divider 142. As a very simple embodiment, a quotient Q may be formed, by dividing the center signal by the sum signal or vice versa. Other options are feasible and are given above.

15

Finally, the evaluation device 132 is configured for determining at least one longitudinal coordinate z of the object by evaluating the combined signal. For this purpose, the evaluation device may comprise at least one further component, such as at least one evaluation component, for example a position evaluation device 144. It shall be noted that the components of the evaluation device 132 shown in Figure 8 may fully or partially be embodied in hardware and/or software. Further, the components may fully or partially be embodied as independent or separate components, and/or may fully or partially be embodied as components which are integrated into the sensor element 115.

20

25

The embodiment of Figure 8 further shows that, in addition to the longitudinal coordinate z , at least one item of information on a transversal coordinate of the object 112 and/or the beacon device 114 may be generated. Thus, the coordinates i^* and j^* provide additional items of information on a transversal position of the object 112 and/or the beacon device 114. In the setup of Figure 6, the beacon device 114, for the sake of simplicity, is positioned in the center, i.e. on the optical axis 126, 129. In this case, the light spot 131 is likely to be centered in the middle of the matrix 117. In the embodiment shown in Figure 8, however, as can easily be detected, the light spot 131 is off-centered. This off-centering is characterized by the coordinates i^* , j^* . By using known optical relationships between this off-centering and a transversal position of the object 112 and/or the beacon device 114, such as by using the lens equation, at least one transversal coordinate of the object 112 and/or the beacon device 114 may be generated. This option is also shown in the exemplary embodiment of Figure 8.

30

35

40

In Figure 7, a modification of the embodiment of Figure 6 is shown, which forms an alternative detector 110. The alternative embodiment of the detector 110 widely corresponds to the embodiment shown in Figure 6. Instead of using an active beacon device 114 with light-emitting

properties for generating the light beam 116, however, the detector 110 itself comprises at least one illumination source 136. The illumination source 136, as an example, may comprise at least one laser, whereas, in Figure 6, as an example, the beacon device 114 may comprise a light-emitting diode (LED). Other embodiments, however, are feasible. The illumination source 136
5 may be configured for generating at least one illumination light beam 138 for fully or partially illuminating the object 112. The illumination light beam 138 is fully or partially reflected by the object 112 and travels back towards the detector 110, thereby forming the light beam 116.

As shown in Figure 7, as an example, the illumination light beam 138 may be parallel to the optical axis 126 of the detector 110. Other embodiments, i.e. off-axis illumination and/or illumination at an angle, are feasible, too. In order to provide an on-axis illumination, as shown in Figure 7, as an example, one or more reflective elements 140 may be used, such as one or more
10 prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms.

Apart from these modifications, the setup of the embodiment in Figure 7 corresponds to the setup in Figure 6. Thus, again, an evaluation device 132 may be used, having e.g. at least one divider 142 for forming the quotient signal Q, and, as an example, at least one position evaluation device 144, for deriving the at least one longitudinal coordinate z from the quotient signal Q and/or another type of combined signal. It shall be noted that the evaluation device 132, again,
20 may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 133, 135, 137, 142, 144 may fully or partially be embodied by appropriate software components and/or may fully or partially be embodied by hardware components.

The optical sensors 113 of the matrix 117, as an example, may be pixels of a pixelated optical sensor, such as a CCD and/or a CMOS sensor chip. Thus, as an example, the optical sensors 113 may have a side length and/or an equivalent diameter in the range of a few micrometers to several hundred micrometers. It shall be noted, however, that larger pixels or optical sensors 113 may be used. Further, instead of using an integrated sensor element 115 such as a CCD and/or CMOS sensor chip, non-integrated matrices may be used.
30

Figure 9 shows, in a highly schematic illustration, an exemplary embodiment of a detector 110, e.g. according to the embodiments in Figures 6 or 7. The detector 110, specifically, may be embodied as the camera 146 and/or may be part of a camera 146. The camera 146 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or
35 image sequences such as digital video clips. Other embodiments are feasible.

Figure 9 further shows an embodiment of a detector system 134, which, besides the at least one detector 110, comprises one or more beacon devices 114, which, in this example, may be attached to and/or integrated into an object 112, the position of which shall be detected by using the detector 110. Figure 9 further shows an exemplary embodiment of a human-machine interface 148, which comprises the at least one detector system 134 and, further, an entertainment device 150, which comprises the human-machine interface 151. The figure further shows an embodiment of a tracking system 152 for tracking a position of the object 112, which comprises
40

the detector system 134. The components of the devices and systems shall be explained in further detail below.

Figure 9 further shows an exemplary embodiment of a scanning system 154 for scanning a scenery comprising the at least one object 112, such as for scanning the object 112 and/or for determining at least one position of the at least one object 112. The scanning system 154 comprises the at least one detector 110 and, further, optionally, the at least one illumination source 136 as well as, optionally, at least one further illumination source 136, which is not shown. The illumination source 136, generally, may be configured to emit the at least one illumination light beam 138, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 114 and/or on a surface of the object 112. It shall be noted, however, that an active beacon device, as e.g. shown in the setup of Figure 6, may also be used, and, thus, that setups with no integrated illumination source 136 are also feasible. The scanning system 154 may be designed to generate a profile of the scenery including the object 112 and/or a profile of the object 112 and/or may be designed to generate at least one item of information about the distance between the at least one dot and the scanning system 154, specifically the detector 110, by using the at least one detector 110.

As outlined above, an exemplary embodiment of the detector 110 which may be used in the setup of Figure 9 is shown in Figures 6 and 7. Thus, the detector 110, besides the sensor element 115, comprises the at least one evaluation device 132, having, e.g., the at least one center detector 133, the at least one summing device 135, the at least one combining device 140, the at least one divider 142, the at least one position evaluation device 144 and/or combinations thereof. These components, which may optionally be present, are symbolically depicted in Figure 9. The components of the evaluation device 132 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 110. Besides the possibility of fully or partially combining two or more components, one or more of the components of the evaluation device 132 and one or more of the components of the sensor element 115 may be interconnected by one or more connectors 156 and/or by one or more interfaces, as symbolically depicted in Figure 9. Further, the one or more connectors 156 may comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 156, the evaluation device 132 may fully or partially be integrated into one or both of the sensor element 115 and/or into a housing 158 of the detector 110. Additionally or alternatively, the evaluation device 132 may fully or partially be designed as a separate device.

In this exemplary embodiment, the object 112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 160, the position of which may be manipulated by a user 162. As an example, the object 112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 112 are possible. Further, the user 162 himself or herself may be considered as the object 112, the position of which shall be detected.

As outlined above, the detector 110 comprises at least the sensor element 115. The sensor 115, wherein one or more of the sensor elements 115 may be provided, may be located inside the housing 158 of the detector 110. Further, the at least one transfer device 128 is comprised, such as one or more optical systems, preferably comprising one or more lenses.

5 An opening 164 inside the housing 158, which, preferably, is located concentrically with regard to the optical axis 126 of the detector 110, preferably defines a direction of view 166 of the detector 110. In the coordinate system 168, symbolically depicted in Figure 9, a longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other
10 types of coordinate systems 168 are feasible, such as non-Cartesian coordinate systems.

The detector 110 may comprise the sensor element 115 as well as, optionally, one or more further optical sensors. A non-branched beam path may be used or, alternatively, a branched beam path may be possible, with, e.g., additional optical sensors in one or more additional
15 beam paths, such as by branching off a beam path for at least one transversal detector or transversal sensor for determining the transversal coordinates of the object 112 and/or parts thereof. As outlined above, however, in the context of Figure 8, the at least one transversal coordinate may also be determined by the sensor element 115 itself, such as by determining the transversal coordinates of the center of the light spot 131.

20 One or more light beams 116 are propagating from the object 112 and/or from one or more of the beacon devices 114, towards the detector 110. The detector 110 is configured for determining a position of the at least one object 112. For this purpose, as outlined above in the context of Figures 6 to 8, the evaluation device 132 may be configured to evaluate the sensor signals
25 provided by the optical sensors 113 of the matrix 117 of the sensor element 115. The detector 110 is adapted to determine a position of the object 112, and the optical sensors 113 are adapted to detect the light beam 116 propagating from the object 112 towards the detector 110, specifically from one or more of the beacon devices 114. In case no illumination source 136 is used, the beacon devices 114 and/or at least one of these beacon devices 114 may comprise
30 active beacon devices with an integrated illumination source such as light-emitting diodes. In case the illumination source 136 is used, the beacon devices do not necessarily have to be active beacon devices. Contrarily, a reflective surface of the object 112 may be used, such as integrated reflective beacon devices 114 having at least one reflective surface. The light beam 116, directly and/or after being modified by the transfer device 128, such as being focused by
35 one or more lenses, illuminates the sensor element 118. For details of the evaluation, reference may be made to Figures 6 to 8 above.

40 As outlined above, the determination of the position of the object 112 and/or a part thereof by using the detector 110 may be used for providing a human-machine interface 148, in order to provide at least one item of information to a machine 170. In the embodiments schematically depicted in Figure 9, the machine 170 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 132 may even be fully or partially integrated into the machine 170, such as into the computer.

As outlined above, Figure 9 also depicts an example of a tracking system 152, configured for tracking the position of the at least one object 112 and/or of parts thereof. The tracking system 152 comprises the detector 110 and at least one track controller 172. The track controller 172 may be adapted to track a series of positions of the object 112 at specific points in time. The track controller 172 may be an independent device and/or may fully or partially be integrated into the machine 170, specifically the computer, as indicated in Figure 9, and/or into the evaluation device 132.

Similarly, as outlined above, the human-machine interface 148 may form part of an entertainment device 150. The machine 170, specifically the computer, may also form part of the entertainment device 150. Thus, by means of the user 162 functioning as the object 112 and/or by means of the user 162 handling a control device 160 functioning as the object 112, the user 162 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer game.

In Figure 10, experimental data are shown which demonstrate an exemplary embodiment of the present invention in terms of measurement data. The figure shows a quotient signal Q as a function of a longitudinal coordinate z , given in millimeters, for various illumination intensities.

In order to gain the experimental data shown in Figure 10, an experimental setup was used with a sensor element 118 formed by a Basler AC 1920-40GC camera, with a transfer device 128 formed by a Nikkor 50 mm lens.

As a beacon device 114, a light-emitting diode (LED) was used, having a central nominal wavelength of 532 nm. A diffusor made from Teflon film was used in front of the LED and a diaphragm, in order to provide a well-defined light-emitting area having a diameter of 5 mm. The intensity of the LED was varied, by varying a drive current of the LED between 5 mA and 150 mA.

In the experiments, the distance z between the LED and the lens was varied from 300 mm to 1700 mm. The signal of the Basler AC 1920-40GC camera was evaluated by the following procedure. As a center signal, an accumulated signal of an inner circle having a radius of 15 pixels around the optical axis was determined, with the light spot centered at the optical axis. As a sum signal, the sum of the signals of all pixels of the camera within the light spot was generated. A quotient signal was formed, by dividing the sum signal by the center signal.

In Figure 10, the solid curves, overlapping, show the quotient signal curves for LED currents of 150 mA, 125 mA, 100 mA and 50 mA. As can be seen, there are basically no differences between these curves, within the whole measurement range. This experiment clearly shows that the quotient signal is widely independent on the total power of the light beam. Only at lower intensities, the curves may be distinguished. Thus, the dotted curve shows measurements at an

LED current of 25 mA, the dashed-dotted line at an LED current of 10 mA, and the dashed line at an LED current of 5 mA. Still, even at these low intensities, the measurement curves are very close to the solid curves, which shows the high tolerances of the measurement.

- 5 In Fig. 11, a schematic view of a further embodiment of a detector 110 for determining a position of at least one object 112 is depicted. In this case, the object 112 comprises the beacon device 114, from which the light beam 116 propagates towards the first optical sensor 118 and the second optical sensor 120. The first optical sensor 118 may comprise a first light-sensitive area 122, and the second optical sensor 120 comprises the second light-sensitive area 124.
- 10 The optical sensors 118, 120, as shown e.g. in Fig. 14, may be part of an array 174 of optical sensors 176, such as the first optical sensor 118 being the optical sensor 176 in the upper left corner of the array 174 and the second optical sensor 120 being the optical sensor 176 in the lower right corner of the array 174. Other choices are feasible. The array 174, as an example, may be a quadrant photodiode 178, and the optical sensors 176 may be partial diodes of the
- 15 quadrant photodiode 178.

The light beam 116, as an example, may propagate along an optical axis 126 of the detector 110. Other embodiments, however, are feasible. The optical detector 110 comprises the at least one transfer device 128, such as at least one lens and/or at least one lens system, specifically

20 for beam shaping. Consequently, the light beam 116 may be focused, such as in one or more focal points 130, and a beam width of the light beam 116 may depend on the longitudinal coordinate z of the object 112, such as on the distance between the detector 110 and the beacon device 114 and/or the object 112. The optical sensors 118, 120 are positioned off focus. In this third preferred embodiment the optical sensors 118, 120 may be arranged such that the light-

25 sensitive areas of the optical sensors differ in their spatial offset and/or their surface areas. For details of this beam width dependency on the longitudinal coordinate, reference may be made to one or more of WO 2012/110924 A1 and/or WO 2014/097181 A1.

As can be seen in Fig. 14, the setup of the detector 110 is off-centered in various ways. Thus, a

30 geometrical center 180 of the array 174 may be off-centered from the optical axis 126, 129 by offset d_0 . Further, a geometrical center 182 of the first optical sensor 118 is off-centered from the optical axis 126 by offset d_1 , and a geometrical center 184 of the second optical sensor 120 is off-centered from the optical axis 126 by offset d_2 , wherein $d_1 \neq d_2$. In other words, a light spot 186 is formed, which is unequally distributed over the light-sensitive areas 122, 124.

35

As will be shown in further detail below, the detector 110 may be configured for automatically establishing the off-centered position of the light spot 186 on the array 174. For this purpose, firstly, the detector 110 may be configured for determining whether the sensor signals generated by the optical sensors 176 of the array 174 are equal. If this should be the case, the detector

40 110 may be configured to determine that the light spot 186 is centered in the array 174 and, consequently, may shift the light spot 186 out of the geometrical center 180 of the array 174, such as by shifting the whole array 174 in a plane perpendicular to the optical axis 126, 129. For

this purpose, as will be shown in further detail below with respect to Fig. 13, one or more actuators may be provided in the detector 110.

Turning back to the setup of Fig. 11, the first optical sensor 118, in response to the illumination by the light beam 116, generates a first sensor signal s_1 , whereas the second optical sensor 120 generates a second sensor signal s_2 . Preferably, the optical sensors 118, 120 are linear optical sensors, i.e. the sensor signals s_1 and s_2 each are solely dependent on the total power of the light beam 116 or of the portion of the light beam 116 illuminating their respective light-sensitive areas 122, 124, whereas these sensor signals s_1 and s_2 are independent from the actual size of the light spot of illumination. In other words, preferably, the optical sensors 118, 120 do not exhibit the above-described FiP effect.

The sensor signals s_1 and s_2 are provided to an evaluation device 132 of the detector 110. The evaluation device 110, as symbolically shown in Fig. 1, may specifically be embodied to derive a quotient signal Q , as explained above. The quotient signal Q , derived by dividing the sensor signals s_1 and s_2 or multiples or linear combinations thereof, may be used for deriving at least one item of information on a longitudinal coordinate z of the object 112 and/or the beacon device 114, from which the light beam 116 propagates towards the detector 110, as will be explained in further detail with reference to the corrosion signals shown in Fig. 16 to 18 below.

The detector 110, in combination with the at least one beacon device 114, may be referred to as the detector system 134, as will be explained in further detail below with reference to Fig. 13.

In Fig. 12, a modification of the embodiment of Fig. 11 is shown, which forms an alternative detector 110. The alternative embodiment of the detector 110 widely corresponds to the embodiment shown in Fig. 11. Instead of using an active light source, i.e. a beacon device 114 with light-emitting properties for generating the light beam 116, however, the detector 110 comprises the at least one illumination source 136. The illumination source 136, as an example, may comprise a laser, whereas, in Fig. 11, as an example, the beacon device 114 may comprise a light-emitting diode (LED). The illumination source 136 may be configured for generating at least one illumination light beam 138 for illuminating the object 112. The illumination light beam 138 is fully or partially reflected by the object 112 and travels back towards the detector 110, thereby forming the light beam 116. The illumination source 136, as an example, may comprise one or more diaphragms 190, such as an adjustable diaphragm 190, e.g. an adjustable iris diaphragm and/or a pin hole.

The setup shown in Fig. 12, as an example, may also be used in or as a readout device 192 for optical storage media. Thus, as an example, the object 112 may be an optical storage medium such as in optical storage discs, e.g. a CCD, DVD or Blu-ray disc. By measuring the presence or non-presence of data storage modules and the depth of the same within the object 112, by using the above-mentioned measurement principle, a data readout may take place.

The light beam 116, specifically, may travel along the optical axis 126 of the detector 110. As shown in Fig. 12, as an example, the illumination light beam 138 may be parallel to the optical axis 126 of the detector 110. Other embodiments, i.e. off-axis illumination and/or illumination at an angle, are feasible, too, as will be shown in the context of Fig. 19A and 19B below. In order to provide an on-axis illumination, as shown in Fig. 12, as an example, one or more reflective elements 140 may be used, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms.

Apart from these modifications, the setup of the embodiment in Fig. 12 corresponds to the setup in Fig. 11. Thus, again, an evaluation device 132 may be used, having, e.g., at least one divider 142 for forming the quotient signal Q , and, as an example, at least one position evaluation device 144, for deriving the at least one longitudinal coordinate z from the at least one quotient signal Q . It shall be noted that the evaluation device 132 may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 142, 144 may be embodied by appropriate software components.

It shall further be noted that the embodiments shown in Fig. 11 and 12 simply provide embodiments for determining the longitudinal coordinate z of the object 112. It is also feasible, however, to modify the setups of Fig. 11 and 12 to provide additional information on a transversal coordinate of the object 112 and/or of parts thereof. As an example, e.g. in between the transfer device 128 and the optical sensors 118, 120, one or more parts of the light beam 116 may be branched off, and may be guided to a position-sensitive device such as one or more CCD and/or CMOS pixelated sensors and/or additional quadrant detectors and/or other position sensitive devices, which, from a transversal position of a light spot generated thereon, may derive a transversal coordinate of the object 112 and/or of parts thereof. For further details, as an example, reference may be made to one or more of the above-mentioned prior art documents which provide for potential solutions of transversal sensors.

Fig. 13 shows, in a highly schematic illustration, an exemplary embodiment of a detector 110, e.g. according to the embodiments shown in Fig. 11 or 12. The detector 110 specifically may be embodied as a camera 146 and/or may be part of a camera 146. The camera 146 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible.

Fig. 13 further shows an embodiment of a detector system 134, which, besides the at least one detector 110, comprises one or more beacon devices 114, which, in this example, may be attached and/or integrated into an object 112, the position of which shall be detected by using the detector 110. Fig. 13 further shows an exemplary embodiment of a human-machine interface 148, which comprises the at least one detector system 134 and, further, an entertainment device 150, which comprises the human-machine interface 148. The figure further shows an embodiment of a tracking system 152 for tracking a position of the object 112, which comprises the detector system 134. The components of the devices and systems shall be explained in further detail below.

Fig. 13 further shows an exemplary embodiment of a scanning system 154 for scanning a scenery comprising the object 112, such as for scanning the object 112 and/or for determining at least one position of the at least one object 112. The scanning system 154 comprises the at least one detector 110, and, further, optionally, the at least one illumination source 136 as well as, optionally, at least one further illumination source 136. The illumination source 136, generally, is configured to emit at least one illumination light beam 138, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 114 and/or on a surface of the object 112. The scanning system 154 may be designed to generate a profile of the scenery including the object 112 and/or a profile of the object 112, and/or may be designed to generate at least one item of information about the distance between the at least one dot and the scanning system 154, specifically the detector 110, by using the at least one detector 110.

As outlined above, an exemplary embodiment of the detector 110 which may be used in the setup of Fig. 13 is shown in Fig. 11 and 12 or will be shown, as an alternative embodiment, in Fig. 15 below. Thus, the detector 110, besides the optical sensors 118, 120, comprises at least one evaluation device 132, having e.g. the at least one divider 142 and/or the at least one position evaluation device 144, as symbolically depicted in Fig. 13. The components of the evaluation device 132 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 110. Besides the possibility of fully or partially combining two or more components, one or more of the optical sensors 118, 120 and one or more of the components of the evaluation device 132 may be interconnected by one or more connectors 156 and/or by one or more interfaces, as symbolically depicted in Fig. 15. Further, the one or more connectors 156 may comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 156, the evaluation device 132 may fully or partially be integrated into one or both of the optical sensors 118, 120 and/or into a housing 158 of the detector 110. Additionally or alternatively, the evaluation device 132 may fully or partially be designed as a separate device.

In Fig. 13, as an example, one or more reflective elements 140 may be used, for example partially transparent, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms.

The detector 110 as symbolically shown in the exemplary embodiment of Fig. 13 may also comprise at least one actuator 188 for moving the array 174 of the optical sensors 176 relative to the optical axis 126. As outlined above, for providing this movement, the optical axis 126 may be moved in relation to the array 174 by moving the optical axis 126, by moving the array 174 or both. Thus, as an example, the optical axis may be moved by using one or more of deflecting elements and/or by using the transfer device 128. As a simple example, a lens of the transfer device 128 may be tilted, such as by using one or more actuators 188 (not depicted). Additionally or alternatively, the array 174 may be shifted by the one or more actuators 188, preferably in

a plane perpendicular to the optical axis 126. As an example, one or more electromechanical actuators may be used, such as one electromechanical actuator for an x-direction and another electromechanical actuator for a y-direction. Other embodiments are feasible. Thereby, the above-mentioned off-centering procedure may be implemented for establishing an off-centered situation as shown e.g. in Fig. 14.

In the exemplary embodiment shown in Fig. 13, further, the object 112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 160, the position of which may be manipulated by a user 162. As an example, the object 112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 112 are possible. Further, the user 162 himself or herself may be considered as the object 112, the position of which shall be detected.

As outlined above, the detector 110 comprises at least the optical sensors 176, including at least the first optical sensor 118 and the second optical sensor 120. The optical sensors 176 may be located inside the housing 158 of the detector 110. Further, the at least one transfer device 128 is comprised, such as one or more optical systems, preferably comprising one or more lenses.

An opening 164 inside the housing 158, which, preferably, is located concentrically with regard to the optical axis 126 of the detector 110, preferably defines a direction of view 166 of the detector 110. In the coordinate system 128, symbolically depicted in Fig. 15, a longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other types of coordinate systems 168 are feasible, such as non-Cartesian coordinate systems.

The detector 110 may comprise the optical sensors 118, 120 as well as, optionally, further optical sensors. The optical sensors 118, 120 preferably are located in one and the same beam path, one behind the other, such that the first optical sensor 118 covers a portion of the second optical sensor 120. Alternatively, however, a branched beam path may be possible, with additional optical sensors in one or more additional beam paths, such as by branching off a beam path for at least one transversal detector or transversal sensor for determining transversal coordinates of the object 112 and/or of parts thereof.

One or more light beams 116 are propagating from the object 112 and/or from one or more of the beacon devices 114, towards the detector 110. The detector 110 is configured for determining a position of the at least one object 112. For this purpose, as explained above in the context of Fig. 11, 12 and 14, the evaluation device 132 is configured to evaluate sensor signals provided by the optical sensors 118, 120. The detector 110 is adapted to determine a position of the object 112, and the optical sensors 118, 120 are adapted to detect the light beam 116 propagating from the object 112 towards the detector 110, specifically from one or more of the beacon devices 114. In case no illumination source 136 is used, the beacon devices 114 and/or at least one of these beacon devices 114 may be or may comprise active beacon devices with an inte-

grated illumination source such as a light-emitting diode. In case the illumination source 136 is used, the beacon devices 114 do not necessarily have to be active beacon devices. Contrarily, a reflective surface of the object 112 may be used, such as integrated reflective beacon devices 114 having at least one reflective surface. The light beam 116, directly and/or after being modified by the transfer device 128, such as being focused by one or more lenses, illuminates the light-sensitive areas 122, 124 of the optical sensors 118, 120. For details of the evaluation, reference may be made to Fig. 11, 12 and 14 above.

As outlined above, the determination of the position of the object 112 and/or a part thereof by using the detector 110 may be used for providing a human-machine interface 148, in order to provide at least one item of information to a machine 170. In the embodiments schematically depicted in Fig. 13, the machine 170 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 132 may even be fully or partially integrated into the machine 170, such as into the computer.

As outlined above, Fig. 13 also depicts an example of a tracking system 152, configured for tracking the position of the at least one object 112 and/or of parts thereof. The tracking system 152 comprises the detector 110 and at least one track controller 172. The track controller 172 may be adapted to track a series of positions of the object 112 at specific points in time. The track controller 172 may be an independent device and/or may be fully or partially integrated into the machine 170, specifically the computer, as indicated in Fig. 13 and/or into the evaluation device 132.

Similarly, as outlined above, the human-machine interface 148 may form part of an entertainment device 150. The machine 170, specifically the computer, may also form part of the entertainment device 150. Thus, by means of the user 162 functioning as the object 112 and/or by means of the user 162 handling a control device 160 functioning as the object 112, the user 162 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer game.

In the setup of the detectors 110 as shown in Fig. 11, 12 and 13, the optical sensors 176 are part of an array 174, and all optical sensors 176 may be located in one and the same plane oriented essentially perpendicular to the optical axis 126. As noted in this context, when mentioning “perpendicular” or “essentially perpendicular”, preferably, a 90° orientation is given. However, tolerances may be present, such as angular tolerances of no more than 20°, preferably of no more than 10° or more preferably of no more than 5°. The optical sensors 176, however, not necessarily have to be located in an array 174 and not necessarily have to be located in one and the same plane, as is shown in an alternative setup of the detector 110 shown in Fig. 15. In this figure, only the optical components are shown. For other components, reference may be made to Fig. 11, 12 and 13 above.

As can be seen, in this alternative setup, two or more optical sensors 176 are present, comprising at least one first optical sensor 118 and at least one second optical sensor 120 located in different planes which are offset in a direction of the optical axis 126, also referred to as the z-direction. Thus, further, as can also be seen, the optical sensors 118, 120 may overlap, whereas in the previous embodiments, preferably, no overlap between the optical sensors 176 is given. Apart from these modifications, the functionality and the evaluation of the sensor signals generally corresponds to the embodiment of Fig. 11, 12 and 13 above.

As discussed above, for evaluating the at least two sensor signals of the at least two optical sensors 176 and for deriving an information on the longitudinal position of the object 112 thereof, such as a distance between the detector 110 and the object 112 and/or a z-coordinate of the object 112, preferably, at least one combined sensor signal is generated by the evaluation device 132. The combined sensor signal, as long as this combined sensor signal provides, at least over a measurement range, a unique function of the distance, may be used for deriving the longitudinal coordinate. As an example, the combined sensor signal may be or may comprise at least one quotient signal Q. In Fig. 16 to 18, quotient signals Q of two sensor signals of two optical sensors 176 are shown under various measurement conditions. In each case, the quotient signal Q is denoted on the vertical axis, as a function of the longitudinal coordinate z of the object 112 on the horizontal axis, the latter given in centimeters.

In all experiments, a setup as shown in Fig. 12 was used. As an illumination source 136, in the experiments of Fig. 16 and 17, a 980 nm Picotronic laser source was used, in conjunction with a lens having a focal length of 100 mm. In the experiment of Fig. 18, a Laser Components laser light source having a wavelength of 850 nm was used, in conjunction with a lens having a focal length of 79 mm. In all experiments, the laser beam was aligned on the optical axis 126 via a small prism in front of the lens 128, forming a reflective element 140. A diaphragm 190 in front of the laser source was used to vary the spot size. The quadrant diode 178 was used to measure the reflection of the laser source on different materials. In all experiments, the distance dependency is given by the quotient Q of two adjacent quadrant currents.

In Fig. 16, the laser power was varied during the experiment, from 8 nA laser current, denoted by the dotted line, to 106 nA, denoted by the solid line. Therein, since the laser current typically does not provide a measure for the laser intensity, the laser current indicated therein is a current of a silicon photodetector in a measurement setup in which the laser illuminates a white sheet of paper at a distance of 330 mm from the lens. As is clearly visible, the curves are nearly identical and, at least within this range of variation of the laser power, do not significantly depend on the laser power. This experiment shows that the quotient signal provides a reliable and monotonous function of the longitudinal coordinate, independent from the influence of the brightness of the illumination source.

In Fig. 17, a spot size of the illumination source 136 was varied, by varying the open diameter of the diaphragm 190 in front of the laser. The spot size was varied from 1.5 mm, denoted by the dotted line, to 3.5 mm, denoted by the solid line, in steps of 0.5 mm. As can be seen, up to a

distance of approximately 200 cm, the quotient signal Q does not depend on the spot size and, thus, again, is not negatively affected by this variation.

In Fig. 18, a material of the object 112 illuminated by the laser beam was varied. Therein, the dotted line denotes white paper, the dashed line with the smallest dashes denotes black paper, the dashed line with the medium dashes denotes wood, and the dashed line with the largest dashes denotes an aluminum plate. As can be seen, at least up to a measurement range of approximately 250 cm, the experiment does not strongly depend on the type of material used for the object 112.

The experiments shown in Fig. 16 to 18, thus, clearly demonstrate that the quotient signal Q provides a reliable function of the distance. At least within a range of measurement, the function monotonously rises with the distance. The function is not strongly influenced by the most significant variations which may occur in real life measurements, such as the brightness of the illumination source, the spot size of the illumination source or the material of the object 112. Thus, by evaluating the quotient signal Q of two or more optical sensors 176, reliable distance information may be generated. Thus, as an example, the curves shown in Fig. 16 to 18 directly may be used as calibration curves for the purpose of the evaluation device 132. Other evaluation methods, however, are feasible.

In Fig. 19A and 19B, an alternative embodiment of the detector 110 is shown which is a modification of the setup shown in Fig. 2. Thus, for most elements and optional details as well as further elements not shown in the schematic Figures 19A and 19B, reference may be made to the description of Fig. 12 above.

In Figure 12, the illumination light beam 138, as discussed above, preferably travels along the optical axis 126, i.e. parallel to the optical axis 126 or even on the optical axis 126. In the setup, the position of the center of the light spot 186 typically does not depend on the z-coordinate of the object 112, such as on a distance between the object 112 and the detector 110. In other words, the diameter or equivalent diameter of the light spot 186 changes with the distance between the object 112 and the detector 110 whereas, typically, the position of the light spot 186 on the array 174 does not.

Contrarily, in Fig. 19A and 19B, a setup of the detector 110 is shown in which an illumination light beam 138 travels off-axis, i.e. one or both of at an angle other than 0° with the optical axis 126 or parallel to the optical axis 126 but shifted from the optical axis 126. This embodiment, as will be discussed in further detail below, demonstrates that the method according to the present invention can be further enhanced by increasing the z-dependency of a combined sensor signal. Thus, in Fig. 19A, a side view is shown with two different positions of the object 112, i.e. a first position at z_1 , drawn in solid lines, and a second position at z_2 , drawn in dashed lines. As can be seen, the illumination light beam 138 which, as an example, propagates at an angle of 5° to 30° , e.g. 10° to 20° , with the optical axis 126, hits the object 112 in both cases at different positions. From these points of the object 112 illuminated by the illumination light beam 138,

light beams 116 propagate towards the detector 110, wherein, again, the light beam 116 for the object 112 being located at position z_1 is drawn in solid lines, wherein the light beam 116 for the object 112 being located at position z_2 is drawn in dashed lines.

5 In Fig. 19B, the array 174, e.g. a quadrant photodiode, is shown in an enlarged fashion. As can be seen in this setup, the position of the light spot 186 moves with the longitudinal position z of the object 112. Thus, not only is the size of the light spot 186 affected by the longitudinal position z but also is the position on the array 174 of the light spot 186 changed. In Fig. 19B, this movement of the light spot 186 is denoted by arrow z .

10

Consequently, by this movement of the light spot 186, the z -dependency of a combined sensor signal taking into account at least two sensor signals of the optical sensors 176 may be increased. As an example, the four diodes of the array 174, in Fig. 19B, are denoted by D1-D4.

15 The quotient signal Q , as an example, may be formed as $Q = i(D1)/i(D4)$, with $i(D1)$ being the sensor signal of photodiode D1, and $i(D4)$ being the sensor signal of photodiode D4. As shown in Figure 19B, the quadrant diode may comprise two dividing lines. The dividing lines may be arranged orthogonal to each other. The orthogonal arrangement of the dividing lines allows adjusting of the quotient signal for near field and far field applications independently from each other.

20 In addition to determining the quotient signal of sensor signals of two optical sensors of the quadrant diode, the evaluation device 132 may be adapted to determine a second quotient using at least three or all four sensor signals of the quadrant diode. The two quotients can be formed such that two distinct distance ranges are covered. The two quotient signals for the near field and far field may have an overlap region in which both quotients allow obtaining reasonable determination of the longitudinal distance z . For example, the quotient may be determined

25 by $Q = i(D1+D2)/i(D3+D4)$, wherein the sensor signals of the two top quadrants, also called top segment, are divided by the sensor signals of the two bottom quadrants, also called bottom segment. Using the quotient of sensor signals determined by two sensor areas which have a dividing line parallel to the baseline of the detector may allow determining of the quotient without any distance dependent movement of the light spot. In particular, as an example, if the dividing

30 line between top and bottom segment is parallel to the baseline, the quotient signal determined from the top segment divided by the bottom segment may be used in the near field, wherein the light spot may illuminate only one of a left or right segment of the quadrant diode. In this case determining the quotient signal by dividing sensor signals of the left and right segments may not be possible. However, determining the quotient by dividing the sensor signals of top and bottom

35 segments may provide a reasonable distance measurement. The quotient signal determined by dividing sensor signals of the left and right segments, i.e. $Q = i(D1+D3)/i(D2+D4)$, may be used for far field measurement, wherein the light spot illuminates both left and right segments. Furthermore, the evaluation device may be adapted to determine the quotient by dividing sensor

40 signals of opposing segments or neighboring segments. The evaluation device may be adapted to combine the acquired sensor signals $i(D1)$, $i(D2)$, $i(D3)$ and $i(D4)$ of the quadrants such that distance measurement is possible over a wide range with a large resolution.

In the situation shown in Fig. 12, the position of the light spot 186 does not depend on z . With a change in z , depending on the optical situation, the spot will become larger or smaller, such as by becoming more diffuse or more focused. In case the spot size increases and the spot becomes more diffuse, $i(D4)$ will increase more rapidly than $i(D1)$, such that the quotient signal Q decreases.

Contrarily, in the situation of Fig. 19A, both the size and the position of the light spot 186 are dependent on the z -coordinate. Thus, the tendency of the z -dependency of the combined sensor signal such as the quotient signal Q will be increased. In the situation of Figure 12, depending on the z -coordinate, the sensor signal of at least one sensor will increase and simultaneously the sensor signal of at least one different sensor will decrease, resulting in the z -dependent quotient signal Q . In the situation of Fig. 19A, the position dependency of the light spot 186 can result in three different situations depending on the relative position of light source, optical axis, and sensor: Firstly, the position dependency of the light spot 186 may result in a further decrease of the at least one decreasing sensor signal depending on the z -coordinate, while, simultaneously, the position dependency of the light spot 186 may result in a further increase of the at least one decreasing sensor signal depending on the z -coordinate compared to the situation in Figure 12. Secondly, the position dependency of the light spot 186 may result in a reduced decrease or even increase of the at least one decreasing sensor signal depending on the z -coordinate, while, simultaneously, the position dependency of the light spot 186 may result in a reduced increase or even decrease of the at least one decreasing sensor signal depending on the z -coordinate compared to the situation in Figure 12. Thirdly, the position dependency of the light spot 186 may be as such that the z -dependence of the sensor signals is largely unchanged compared to the situation in Figure 12. However, according to the present invention, object distance is not determined from the position of the light spot 186 on a sensor as done in triangulation methods. Instead, movement of the light spot 186 on the array 174 may be used to enhance dynamic of the sensor signals and or the resulting quotient signal Q which may result in an enhanced dynamic of the z -dependency. Furthermore, movement of the light spot 186 on the array 174 during measurement may be used to establish and/or to enhance object size independence for the whole measurement range by suitable relative positioning of the optical sensor 176 and the illumination source 136. Thus, movement of the light spot 186 may not be used for the purpose of triangulation but for the purpose of object size independence.

Additionally, as known from the prior art, the sensor signals $i(D1)$, $i(D2)$, $i(D3)$, $i(D4)$ may also be used for determining a transversal position x , y of the object 112. Further, the sensor signals may also be used for verifying the z -coordinate determined by the present invention.

Figure 19C shows a comparison of two experimental setups using a detector setup according to Figure 19A with a Bi-cell as optical sensors 176 with two light sensitive areas. In a first experimental setup, depending on the relative position of the illumination light source, the optical axis and the sensor, the light spot 186 may move in parallel to the linear boundary of the two optical sensors 176 of the Bi-cell along a direction of movement 210 in dependence of the object distance. Since the direction of movement 210 of the light spot 186 is in parallel to the linear

boundary of the two light sensitive areas in dependence of the object distance, the resulting sensor signals are identical to a situation with no movement of the light spot 186 depending on object distance as shown in Figure 12. In a second experimental setup, depending on the relative position of the illumination light source, the optical axis and the sensor, the light spot 186 may move as such that the distance of the center of the light spot 186 to the boundary of the two optical sensors 176 of the Bi-cell changes in dependence of the object distance such as a movement orthogonal to the boundary of the two optical sensors 176 such as a movement along a direction of movement 208 in dependence of the object distance. The detector setup allowing movement of the light spot 186 may be a modification of the setup shown in Figure 19A. Thus, for most elements and optional details as well as further elements, reference may be made to the description of Fig. 19A above. In Figure 19C, the optical sensors 176 may be a bi-cell diode.

Figure 19D shows experimental results of the comparison of the two experimental setups using a detector setup according to Figure 19A, allowing movement of the light spot 186 according to Figure 19C with movement of the light spot depending on the object distance along directions of movement 210 and 208. Curve 212 shows the dependency of quotient Q on the longitudinal coordinate z for the detector setup allowing movement of the light spot 186 along a direction of movement 210 as shown in Figure 19C which is in parallel to the boundary of the optical sensors of the Bi-Cell and, which is a situation equivalent to Figure 12 without a movement of the light spot depending on the object distance. Curve 214 shows the dependency of quotient Q on the longitudinal coordinate z for the detector setup according to Figure 19A and using a detector setup allowing movement of the light spot 186 with movement of the light spot 186 according to Figure 19C with movement of the light spot depending on the object distance along a direction of movement 208. The experimental setup was as follows: The optical sensors 176 may be a bi-cell diode, in particular a Si-Bi-Cell. The illumination source 136 may be a 950 nm laser with a spot size of 4 mm. The transfer device 128 may have a focal length of 20 mm, e.g. a lens available as Thorlabs Asphere, $f = 20$ mm. The distance of the object 112 was varied from 0 to 3000 mm. Determination of the longitudinal coordinate z may be possible without allowing movement of the light spot 186. In particular, according to the present invention, movement of the light spot may not be essential for determination of the longitudinal coordinate z . With the detector setup allowing movement of the light spot 186 along a direction 210 or without any movement determination of object distance is possible at very small distance, whereas with movement along a direction 208 determination of object distance is possible for object distance such as distances greater than 500mm.

Figure 19E shows object independence of the two experimental setups using a detector setup according to Figure 19A, allowing movement of the light spot 186 according to Figure 19C with movement of the light spot depending on the object distance along directions of movement 208 and 210. In addition, for both experimental setups, the object size was varied from 1mm (dashed line), 2mm (dotted line), 6mm (solid line) and 12mm (loosely dotted line) by varying the aperture of the laser illumination source. Set of curves 216 shows dependency of quotient Q on the longitudinal coordinate z for the experimental setup allowing movement of the light spot 186

along a direction 208. Set of curves 218 shows dependency of quotient Q on the longitudinal coordinate z for the experimental setup allowing movement of the light spot 186 along a direction 210 or without any movement. Set of curves 216 show only small deviations, in particular less than 5%, whereas set of curves 218 show larger deviations, in particular with increasing distance z . Thus, movement of the light spot 186 on the array 174 during measurement may be used to establish and/or to enhance object size independence for the whole measurement range by suitable relative positioning of the optical sensor 176 and the illumination source 136.

In Fig. 20, a schematic view of a further embodiment of a detector 1110 for determining a position of at least one object 1112 is depicted. In this case, the object 1112 may comprise a beacon device 1114, from which a light beam 1116 propagates towards a first optical sensor 1118 and a second optical sensor 1120. The first optical sensor 1118 comprises a first light-sensitive area 1122, and the second optical sensor 1120 comprises a second light-sensitive area 1124. Details of the second optical sensor 1120 and the second light-sensitive area 124 will be explained in further detail below, with reference to Fig. 22A, 22B and 23.

It shall be noted therein, that, in the embodiment shown in Fig. 20, the first optical sensor 1118 is positioned in front of the second optical sensor 1120, such that the light beam 1116 reaches the first optical sensor 1118 before the second optical sensor 1120. As discussed above, however, another order is feasible. Thus, as an example, the second optical sensor 1120 may be positioned in front of the first optical sensor 1118. The latter option, which is not depicted herein, is specifically possible in case the second light-sensitive area 1124 is fully or partially transparent, such as by providing a transparent fluorescent waveguiding sheet 1174, as will be outlined in further detail below.

The light beam 1116, as an example, may propagate along an optical axis 1126 of the detector 1110. Other embodiments, however, are feasible.

The detector 1110, further, may comprise at least one transfer device 1128, such as at least one lens or a lens system, specifically for beam shaping. Consequently, the light beam 1116 may be focused, such as in one or more focal points 1130, and a beam width of the light beam 1116 may depend on a longitudinal coordinate z of the object 1112, such as on a distance between the detector 1110 and the beacon device 1114 and/or the object 1112. For details of this beam width dependency on the longitudinal coordinate, reference may be made to one or more of WO 2012/110924 A1 and/or WO 2014/097181 A1.

As can be seen in Fig. 20, the first optical sensor 1118 is a small optical sensor, whereas the second optical sensor 1120 is a large optical sensor. Thus, the width of the light beam 1116 fully may cover the first light-sensitive area 1122, whereas, on the second light-sensitive area 1124, a light spot is generated which is smaller than the light-sensitive area 1124, such that the light spot is fully located within the second light-sensitive area 1124. Possible embodiments will be explained below with reference to Fig. 23. Thus, as an example, the first light-sensitive area 1122 may have a surface area of 10 mm^2 to 100 mm^2 , whereas the second light-sensitive area

1124 may have a surface area of more than 100 mm², such as 200 mm² or more, e.g. 200 to 600 mm² or 500 mm² or more. Other embodiments, however, are feasible.

5 The first optical sensor 1118, in response to the illumination by the light beam 1116, may generate a first sensor signal s_1 , and the second optical sensor 1120 may generate at least one second sensor signal s_2 . As an example, the first optical sensor 1118 may be a linear optical sensor, i.e. the sensor signal s_1 is dependent on the total power of the light beam 1116 or on the portion of the light beam 1116 illuminating the first light-sensitive area 1122, whereas the sensor signal s_1 is independent from the actual size of the light spot of illumination. In other words, the
10 first optical sensor 1118, preferably, does not exhibit the above-described FiP effect.

The sensor signals s_1 and s_2 may be provided to an evaluation device 1132 of the detector 1110. The evaluation device 1110, as symbolically depicted in Fig. 20, may specifically be embodied to derive a quotient signal Q , as explained above. The quotient signal Q , derived by dividing e.g. the sensor signals s_1 and s_2 or multiples or linear combinations thereof, may be used
15 for deriving at least one item of information on a longitudinal coordinate z of the object 1112 and/or the beacon device 1114, from which the light beam 1116 propagates towards the detector 1110. Thus, as an example, a unique evaluation curve may exist, in which, for each quotient signal Q , a longitudinal coordinate z is assigned.

20 The detector 1110, in combination with the at least one beacon device 1114, may be referred to as a detector system 1134, as will be explained in further detail below, with reference to Fig. 25.

In Fig. 21, a modification of the embodiment of Fig. 20 is shown, which forms an alternative detector 1110. The alternative embodiment of the detector 1110 widely corresponds to the embodiment shown in Fig. 20. Instead of using an active light source, i.e. a beacon device 1114 with light-emitting properties for generating the light beam 1116, however, the detector 1110 may comprise at least one illumination source 1136. The illumination source 1136, as an example, may comprise a laser, whereas, in Fig. 20, as an example, the beacon device 1114 may comprise a light-emitting diode (LED). The illumination source 1136 may be configured for generating at least one illumination light beam 1138 for illuminating the object 1112. The illumination light beam 1138 may fully or partially be reflected by the object 1112 and may travel back towards the detector 1110, thereby forming the light beam 1116.

35 As shown in Fig. 20, as an example, the illumination light beam 1138 may be parallel to the optical axis 1126 of the detector 1110. Other embodiments, i.e. off-axis illumination and/or illumination at an angle, are feasible, too. In order to provide an on-axis illumination, as shown in Fig. 21, as an example, one or more reflective elements 1140 may be used, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms.

40 Apart from these modifications, the setup of the embodiment in Fig. 21 corresponds to the setup in Fig. 20. Thus, again, an evaluation device 1132 may be used, having, e.g., at least one divider 1142 for forming the quotient signal Q , and, as an example, at least one position evaluation

device 1144, for deriving the at least one longitudinal coordinate z from the quotient signal Q . It shall be noted that the evaluation device 1132 may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 1142, 1144 may be embodied by appropriate software components.

It shall be further noted that the embodiments shown in Fig. 20 and 21 simply provide embodiments for determining the longitudinal coordinate of the object 1112. As will be outlined in further detail below with reference to Fig. 22A and 22B as well as to Fig. 23, the detector 1110 may also be used for providing additional information on at least one transversal coordinate of the object 1112 and/or of parts thereof.

In Fig. 22A and 22B, a top view (Fig. 22A) and a cross-sectional view of the second optical sensor 1120, which may be used in the setups e.g. of Fig. 20 and/or 21, is shown. The second optical sensor 1120 may comprise a fluorescent waveguiding sheet 1174 which forms the second light-sensitive area 1124 facing towards the object 1112. The fluorescent waveguiding sheet 1174, in this exemplary embodiment, may be designed as a flat waveguiding sheet, in which, as symbolically depicted by the arrow 1176 in Fig. 22B, waveguiding by internal reflection may take place, specifically by internal total reflection, specifically a waveguiding of fluorescence light generated within the fluorescent waveguiding sheet 1174. The fluorescent waveguiding sheet 1174, as an example, may have a lateral extension of at least 25 mm², such as at least 100 mm², more preferably of at least 400 mm². As an example, a 10 mm x 10 mm square sheet, a 20 mm x 20 mm square sheet, a 50 mm x 50 mm square sheet or another dimension may be used. It shall be noted, however, that non-square geometries or even non-rectangular geometries may be used, such as circular or oval geometries or polygonal geometries.

The fluorescent waveguiding sheet 1174, as an example, may comprise a matrix material 1178 and at least one fluorescent material 1180 disposed therein, such as at least one fluorophore, e.g. a fluorescent dye. For exemplary embodiments, reference may be made to the above-mentioned materials, such as one or more of the materials listed in WO 2012/168395 A1. As an example, the following fluorescent material may be used:

This fluorescent material is disclosed as substance 34.2 in WO 2012/168395 A1, including potential synthesis methods. The material may be immersed in polystyrene, such as at a concentration of 0.001 - 0.5 wt.%. The fluorescent material 1180 may be designed to generate fluorescence light in response to an illumination by the light beam 1116.

The fluorescent material 1180 and/or the concentration of the fluorescent material 1180 within the matrix material 1178, specifically may be chosen to show linear properties, at least within a range of measurement, i.e. within a range of intensities, such that the total power of the fluorescence light generated in response to an excitation is a linear function of the intensity of the illumination by the excitation light, i.e. by the light beam 1116. As an example, the materials and/or intensities may be chosen such that saturation effects are avoided.

The second optical sensor 1120 further, in this embodiment, may comprise a plurality of photosensitive elements 1182, 1184, 1186, 1188, in Fig. 22A and 22B referred to as PD1-PD4, located at respective edges 190, 192, 194, 196 of the fluorescent waveguiding sheet 174, e.g. rim portions of the fluorescent waveguiding sheet 1174. In this exemplary embodiment, the fluorescent waveguiding sheet 1174 may have a rectangular shape, such that pairs of edges are opposing each other, such as the pair of edges 1190, 1192 and the pair of edges 1194, 1196. The sides of the rectangular shape of the fluorescent waveguiding sheet 174 may define a Cartesian coordinate system, with an x-dimension defined by an interconnection between edges 1190 and 192, and a y-dimension defined by an interconnection between edges 1196, 1194, as indicated in Fig. 22A. It shall be noted, however, that other coordinate systems are feasible.

The photosensitive elements 1182, 1184, 1186, 1188, as an example, may comprise photodiodes. Specifically, these photosensitive elements 1182, 1184, 1186, 1188 may have, each, a comparable, preferably an identical, electrical capacity as the first optical sensor 1118. It shall be noted, however, that other embodiments are feasible. The photosensitive elements 1182, 1184, 1186, 1188, as an example, may be or may comprise strip-shaped photodiodes covering, preferably, the full length of the respective edges 1190, 1192, 1194, 1196, or, preferably, covering at least 50 % or more preferably at least 70 % of the length of these respective edges 1190, 1192, 1194, 1196. Other embodiments, however, are feasible, such as embodiments in which more than one photosensitive element is located at a respective edge.

The photosensitive elements 1182, 1184, 1186, 1188 each produce at least one sensor signal, in response to the light, specifically the fluorescence light, detected by these photosensitive elements 1182, 1184, 1186, 1188. All of these sensor signals are referred to as second sensor signals, wherein, in the following, PD1 creates sensor signal $s_{2,1}$, PD2 creates sensor signal $s_{2,2}$, PD3 creates sensor signal $s_{2,3}$, and PD4 creates sensor signal $s_{2,4}$, with the first index 2 denoting the fact that these sensor signals are second sensor signals, and with the second index, from 1 to 4, indicating the respective photosensitive element 1182, 1184, 1186, 1188 from which the respective sensor signal originates.

As outlined above in Fig. 20 and 21, the at least one first sensor signal s_1 and the second sensor signals $s_{2,j}$ (with $j = 1, \dots, 4$) are provided to the evaluation device 1132 of the detector 1110, the function of which will be explained in further detail below, specifically with reference to Fig. 24.

5

The evaluation device 1132 is configured to determine at least one longitudinal coordinate z of the object 1112, which is not depicted in these figures, and from which the light beam 1116 propagates towards the detector 1110, by evaluating the first and second sensor signals. Additionally as will be outlined in further detail below, at least one transversal coordinate x and/or y may be determined, as will also be outlined in further detail below, with reference to Fig. 3 and 24.

10

15

20

25

The second optical sensor 1120, as depicted in Fig. 22B, may further optionally comprise at least one optical filter element 1198. The optical filter element 1198 may be placed in front of an optional reference photosensitive element 1200, which may further, with or without the optical filter element 1198, be present in the detector 1110. As an example, the reference photosensitive element 1200 may comprise a large area photodiode. Other setups, however, are feasible. Thus, it shall be noted, that the reference photosensitive element 1200 may also be left out in this embodiment, since the first optical sensor 1118 may also take over the functionality of the reference photosensitive element 1200. Specifically, in case a transparent fluorescent waveguiding sheet 1174 is used and in case the first optical sensor 1118 is placed behind the second optical sensor 1120, the first optical sensor 1118 may also take over the functionality of the reference photosensitive element 1200. It shall further be noted that one or both of the first optical sensor 1118 and the second optical sensor 1120 may be a uniform optical sensor, having a single light-sensitive area 1122, 1124, each, or that one or both of these optical sensors 1118, 1120 may be pixelated.

30

As an example, the at least one optical filter element 1198 may be designed to prevent fluorescence light from entering the reference photosensitive element 1200 or, at least, may attenuate fluorescence light by at least 70 %, or, preferably, by at least 80 %.

35

40

In Fig. 23, an illumination of the second light-sensitive area 1124 by the light beam 1116 is shown. Therein, two different situations are depicted, representing different distances between the object 1112 and from which the light beam 1116 propagates towards the detector 1110, and the detector 1110 itself, resulting in two different spot sizes of light spots generated by the light beam in the fluorescent waveguiding sheet 1174. Firstly, a small light spot 1202 and, secondly, a large light spot 1204. In both cases, the overall power of the light beam remains the same over light spots 1202, 1204. Further, a shadow 1206 is depicted, which is generated by the first optical sensor 1118 being placed in front of the second optical sensor 1120. In the following, it is assumed that the first optical sensor 1118 is still fully illuminated by the light beam 1116.

The illumination by the light beam 1116 induces fluorescence which, as depicted in Fig. 22B above, is fully or partially transported by waveguiding towards the photosensitive elements

1182, 1184, 1186, 1188. As indicated above, corresponding second sensor signals are generated by these photosensitive elements, and are provided to the evaluation device 1132, in conjunction with the first sensor signal and, optionally, further in conjunction with at least one reference sensor signal generated by the at least one reference photosensitive element 1200.

5

The evaluation device 1132, as symbolically depicted in Fig. 24, is designed to evaluate the sensor signals which, therein, are represented as outlined above. The sensor signals may be evaluated by the evaluation device in various ways, in order to determine a location information and/or a geometrical information of the object 1112, such as at least one longitudinal coordinate z of the object 1112 and, optionally, one or more transversal coordinates of the object 1112.

10

Firstly, the evaluation device 1132 may comprise at least one summing device 1208 configured to form a sum signal S of the sensor signals PD1 to PD4, such as according to formula (1) above, for the second sensor signals $s_{2,i}$, with $i = 1, \dots, 4$ (the first index, for the sake of simplicity, is left out in the above-mentioned formula (1)). This sum signal S may replace the second sensor signal s_2 in general and/or, for a part of the further evaluation, may be used as "the" second sensor signal of the second optical sensor 1120. This sum signal S may represent the total power of the fluorescence light generated by the light beam 1116. Even though, some losses may occur, since, generally, not all of the fluorescence light will actually reach the photosensitive elements 1182, 1184, 1186, 1188. Thus, as an example, losses in waveguiding may occur, or some of the fluorescence light may actually be emitted from the edges 1190, 1192, 1194, 1196, in a direction which is not covered by the photosensitive elements 1182, 1184, 1186, 1188. Still, the sum signal S provides a fairly good measure for the total power of the fluorescence generated within the fluorescent waveguiding sheet 1174.

15

20

25

The evaluation device 1132 may comprise at least one divider 1142 which, as symbolically depicted in Fig. 24, may be part of a position evaluation device 1144 and which may be configured for forming at least one quotient signal out of the first and second sensor signals s_1 , s_2 , with s_2 , as an example, being the sum signal S of the respective second sensor signals, as outlined above. Thus, as an example, the divider 1142 may be configured for one or more of dividing the first and second sensor signals, dividing multiples of the first and second sensor signals or dividing linear combinations of the first and second sensor signals. The position evaluation device 1144 further may be configured for determining the at least one longitudinal coordinate z by evaluating the quotient signal Q , such as by using at least one predetermined or determinable relationship between the quotient signal Q and the longitudinal coordinate. As an example, calibration curves may be used. The divider 1142 and/or the position evaluation device 1144 may, as an example, comprise at least one data processing device, such as at least one processor, at least one DSP, at least one FPGA and/or at least one ASIC. Further, for storing the at least one predetermined or determinable relationship between the longitudinal coordinate z and the quotient signal, at least one data storage device may be provided, such as for providing one or more look-up tables for storing the predetermined relationship.

30

35

40

As outlined above, additional information may be derived from the second sensor signals $s_{2,1}$, $s_{2,2}$, $s_{2,3}$ and $s_{2,4}$, besides the at least one longitudinal coordinate z of the object. Thus, additionally, at least one transversal coordinate x , y may be derived. This is mainly due to the fact that the distances between a center of the light spots 1202, 1204 and the photosensitive elements 1182, 1184, 1186, 1188 are non-equal. Thus, the center of the light spot 1202, 1204 has a distance from the photosensitive element 1182 of l_1 , a distance from the photosensitive element 1184 of l_2 , from the photosensitive element 1186 of l_3 and from the photosensitive element 1188 of l_4 . Due to the differences in these distances between the location of the generation of the fluorescence light and the photosensitive elements detecting said fluorescence light, the sensor signals will differ. This is due to various effects. Firstly, again, internal losses will occur during waveguiding, since each internal total reflection implies a certain loss, such that the fluorescence light will be attenuated on its way, depending on the length of the path. The longer the distance of travel, the higher the attenuation and the higher the losses. Further, absorption effects will occur. Thirdly, a spreading of the light will have to be considered. The longer the distance between the light spot 1202, 1204 to the respective photosensitive element 1182, 1184, 1186, 1188, the higher the probability that a photon will be directed into a direction other than the photosensitive element. Consequently, by comparing the sensor signals of the photosensitive elements 1182, 1184, 1186, 1188, at least one item of information on a transversal coordinate of the light spot 1202, 1204 and, thus, of the object 1112 may be generated.

The comparison of the sensor signals may take place in various ways. Thus, generally, the evaluation device 1132 may be designed to compare the sensor signals in order to derive the at least one transversal coordinate of the object 1112 and/or of the light spot 1202, 1204. As an example, the evaluation device 1132 may comprise at least one subtracting device 1210 and/or any other device which provides a function which is dependent on at least one transversal coordinate, such as on the coordinates x , y , of the object 1112. For exemplary embodiments, the subtracting device 1210 and/or any other device may provide a function which is dependent on at least one transversal coordinate, such as on the coordinates x , y . For exemplary embodiments, the subtracting device 1210 may be designed to generate at least one difference signal, such as a signal according to formula (4) and/or (5) above, for one or each of dimensions x , y in Fig. 23. As an example, a simple difference between PD1 and PD2, such as $PD1 - PD2 / (PD1 + PD2)$ may be used, as a measure for the x -coordinate, and a difference between PD3 and PD4, such as $(PD3 - PD4) / (PD3 + PD4)$, may be used as measure for the y -coordinate. A transformation of the transversal coordinates of the light spot 1202, 1204 in the plane of the second light-sensitive area 1124, as an example, into transversal coordinates of the object from which the light beam 1116 propagates to the detector 1110, may simply be made by using the well-known lens equation. For further details, as an example, reference may be made to WO 2014/097181 A1.

It shall be noted, however, that other transformations or other algorithms for processing the sensor signals by evaluating device 1140 are feasible. Thus, besides subtractions or the linear combinations with positive or negative coefficients, non-linear transformations are generally feasible. As an example, for transforming the sensor signals into z -coordinates and/or x , y -

coordinates, one or more known or determinable relationships may be used, which, as an example, may be derived empirically, such as by calibrating experiments with the object placed at various distances from the detector 1110 and/or by calibrating experiments with the object placed at various transversal positions or three-dimensional positions, and by recording the respective sensor signals.

Fig. 25 shows, in a highly schematic illustration, an exemplary embodiment of a detector 1110, e.g. according to the embodiments shown in Fig. 20 or 21. The detector 1110 specifically may be embodied as a camera 1146 and/or may be part of a camera 1146. The camera 1146 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible.

Fig. 25 further shows an embodiment of a detector system 1134, which, besides the at least one detector 1110, comprises one or more beacon devices 1114, which, in this example, may be attached and/or integrated into an object 1112, the position of which shall be detected by using the detector 1110. Fig. 25 further shows an exemplary embodiment of a human-machine interface 1148, which comprises the at least one detector system 1134 and, further, an entertainment device 1150, which comprises the human-machine interface 1148. The figure further shows an embodiment of a tracking system 1152 for tracking a position of the object 1112, which comprises the detector system 1134. The components of the devices and systems shall be explained in further detail below.

Fig. 25 further shows an exemplary embodiment of a scanning system 1154 for scanning a scenery comprising the object 1112, such as for scanning the object 1112 and/or for determining at least one position of the at least one object 1112. The scanning system 1154 comprises the at least one detector 1110, and, further, optionally, the at least one illumination source 1136 as well as, optionally, at least one further illumination source 1136. The illumination source 1136, generally, is configured to emit at least one illumination light beam 1138, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 1114 and/or on a surface of the object 1112. The scanning system 1154 may be designed to generate a profile of the scenery including the object 1112 and/or a profile of the object 1112, and/or may be designed to generate at least one item of information about the distance between the at least one dot and the scanning system 1154, specifically the detector 1110, by using the at least one detector 1110. In Fig. 13, as an example, one or more reflective elements 1140 may be used, for example partially transparent, such as one or more prisms and

As outlined above, an exemplary embodiment of the detector 1110 which may be used in the setup of Fig. 25 is shown in Fig. 20 and 21. Thus, the detector 1110, besides the optical sensors 1118, 1120, comprises at least one evaluation device 1132, having e.g. the at least one divider 1142 and/or the at least one position evaluation device 1144, as symbolically depicted in Fig. 25. The components of the evaluation device 1132 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 1110. Besides the possibility of fully or partially combining two or more components, one or

more of the optical sensors 1118, 1120 and one or more of the components of the evaluation device 1132 may be interconnected by one or more connectors 1156 and/or by one or more interfaces, as symbolically depicted in Fig. 25. Further, the one or more connectors 1156 may comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 1156, the evaluation device 1132 may fully or partially be integrated into one or both of the optical sensors 1118, 1120 and/or into a housing 1158 of the detector 1110. Additionally or alternatively, the evaluation device 1132 may fully or partially be designed as a separate device.

In this exemplary embodiment, the object 1112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 1160, the position of which may be manipulated by a user 1162. As an example, the object 1112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 1112 are possible. Further, the user 1162 himself or herself may be considered as the object 1112, the position of which shall be detected.

As outlined above, the detector 1110 comprises at least the optical sensors 1118, 1120. The optical sensors 1118, 1120 may be located inside the housing 1158 of the detector 1110. Further, the at least one transfer device 1128 may be comprised, such as one or more optical systems, preferably comprising one or more lenses.

An opening 1164 inside the housing 1158, which, preferably, is located concentrically with regard to the optical axis 1126 of the detector 1110, preferably defines a direction of view 1166 of the detector 1110. A coordinate system 1168 may be defined, in which a direction parallel or anti-parallel to the optical axis 1126 may be defined as a longitudinal direction, whereas directions perpendicular to the optical axis 1126 may be defined as transversal directions. In the coordinate system 1128, symbolically depicted in Fig. 25, a longitudinal direction is denoted by z , and transversal directions are denoted by x and y , respectively. Other types of coordinate systems 1168 are feasible, such as non-Cartesian coordinate systems.

The detector 1110 may comprise the optical sensors 1118, 1120 as well as, optionally, further optical sensors. The optical sensors 1118, 1120 preferably are located in one and the same beam path, one behind the other, such that the first optical sensor 1118 covers a portion of the second optical sensor 1120. Alternatively, however, a branched beam path may be possible, with additional optical sensors in one or more additional beam paths, such as by branching off a beam path for at least one transversal detector or transversal sensor for determining transversal coordinates of the object 1112 and/or of parts thereof.

One or more light beams 1116 are propagating from the object 1112 and/or from one or more of the beacon devices 1114, towards the detector 1110. The detector 1110 is configured for determining a position of the at least one object 1112. For this purpose, as explained above in the context of Fig. 20 to 23, the evaluation device 1132 is configured to evaluate sensor signals

provided by the optical sensors 1118, 1120. The detector 1110 is adapted to determine a position of the object 1112, and the optical sensors 1118, 1120 are adapted to detect the light beam 1116 propagating from the object 1112 towards the detector 1110, specifically from one or more of the beacon devices 1114. In case no illumination source 1136 is used, the beacon devices 1114 and/or at least one of these beacon devices 1114 may be or may comprise active beacon devices with an integrated illumination source such as a light-emitting diode. In case the illumination source 1136 is used, the beacon devices 1114 do not necessarily have to be active beacon devices. Contrarily, a reflective surface of the object 1112 may be used, such as integrated reflected beacon devices 1114 having at least one reflective surface. The light beam 1116, directly and/or after being modified by the transfer device 1128, such as being focused by one or more lenses, illuminates the light-sensitive areas 1122, 1124 of the optical sensors 1118, 1120. For details of the evaluation, reference may be made to Fig. 20 to 23 above.

As outlined above, the determination of the position of the object 1112 and/or a part thereof by using the detector 1110 may be used for providing a human-machine interface 1148, in order to provide at least one item of information to a machine 1170. In the embodiments schematically depicted in Fig. 25, the machine 1170 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 1132 may even be fully or partially integrated into the machine 1170, such as into the computer.

As outlined above, Fig. 25 also depicts an example of a tracking system 1152, configured for tracking the position of the at least one object 1112 and/or of parts thereof. The tracking system 1152 comprises the detector 1110 and at least one track controller 1172. The track controller 1172 may be adapted to track a series of positions of the object 1112 at specific points in time. The track controller 1172 may be an independent device and/or may be fully or partially integrated into the machine 1170, specifically the computer, as indicated in Fig. 25 and/or into the evaluation device 1132.

Similarly, as outlined above, the human-machine interface 1148 may form part of an entertainment device 1150. The machine 1170, specifically the computer, may also form part of the entertainment device 1150. Thus, by means of the user 1162 functioning as the object 1112 and/or by means of the user 1162 handling a control device 1160 functioning as the object 1112, the user 1162 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer game.

In Fig. 26A and 26B, an alternative embodiment of the second optical sensor 1120 is shown, in a top view (Fig. 26A) and in a cross-sectional view (Fig. 26B). For most of the details of the second optical sensor 1120, reference may be made to Fig. 22A and 22B above. The embodiment, however, shows various variations from the embodiment of Fig. 22A and 22B, which may be realized in an isolated fashion or in combination.

Thus, firstly, the embodiment shows variations of the placement of the photosensitive elements. Besides the photosensitive elements 1182, 1184, 1186, 1188 located at opposing edges 1190, 1192, 1194, 1196, which, in this embodiment, are straight edges, additional photosensitive elements 1212 are located at corners 1214 of the fluorescent waveguiding sheet 1174. The edges 1190, 1192, 1194, 1196 in combination may form a rim of the fluorescent waveguiding sheet 1174, such as a rectangular rim. The rim itself may be roughened or even blackened in order to avoid back reflections from the rim. The corners 1214 also are part of the edges of the fluorescent waveguiding sheet 1174. The photosensitive elements 1212 located at the corners 1214 may provide additional second sensor signals which may be evaluated in a similar fashion as shown e.g. in Fig. 24. They may provide an increased accuracy of the determination of the z-coordinate and/or of the x, y-coordinate. Thus, as an example, these additional sensor signals may be included in the sum signal, such as formed by using formula (1) above. Additionally or alternatively, these additional sensor signals may be implemented into the formation of difference signals, such as according to formulae (2) and/or (3) above. As an example, difference signals between two photosensitive elements 1212 located at opposing corners 1214 may be formed and/or difference signals between one photosensitive element 1212 located at a corner 1214 and one photosensitive element located at a straight edge, e.g. a straight rim portion, may be formed. The difference signal D, in each case, may denote a location of the light spot on an axis interconnecting the two photosensitive elements.

Further, the embodiment of Fig. 26A and 26B shows a variation of the placement of the photosensitive elements 1182, 1184, 1186, 1188, 1212 with respect to the fluorescent waveguiding sheet 1174. Thus, in the embodiment of Fig. 22A and 22B, the photosensitive elements 1182, 1184, 1186, 1188 may be located within the plane of the fluorescent waveguiding sheet 1174. Additionally or alternatively, as shown in the embodiment of Fig. 26A and 26B, some or even all of the photosensitive elements 1182, 1184, 1186, 1188, 1212 may be located outside the plane of the fluorescent waveguiding sheet 1174. Specifically, as shown in the cross-sectional view of figure 26B, as an example, the photosensitive elements 1182, 1184, 1186, 1188, 1212 may be optically coupled to the fluorescent waveguiding sheet 1174 by optical coupling elements 1216. As an example, the photosensitive elements 1182, 1184, 1186, 1188, 1212 simply may be glued to the fluorescent waveguiding sheet 1174 by using one or more transparent adhesives, such as an epoxy adhesive.

Further, the embodiment of Fig. 26A and 26B shows a variation of the size and shape of the photosensitive elements 1182, 1184, 1186, 1188, 1212. Thus, the photosensitive elements 1182, 1184, 1186, 1188, 1212 do not necessarily have to be strip-shaped photosensitive elements. As an example, very small photodiodes may be used, such as rectangular photodiodes or even point-like or spot-like photodiodes. As outlined above, a small size of the photodiodes generally may lead to a lower electrical capacitance and, thus, may lead to a faster response of the second optical sensor 1120.

Further, the embodiment of Fig. 26A and 26B shows that no reference photosensitive element 1200 is necessary. Thus, as discussed above, the sum signal itself may replace the function of

the reference photosensitive element 1200. Thus, the second optical sensor 1120 as shown in the embodiment of Fig. 26A and 26B provides a fully functional and, optionally, transparent PSD. No further PSDs are required.

5 Figures 27A and 27 B show a schematic view of a further exemplary embodiment of a detector 110 according to the present invention. In Figure 27 A, the detector 110 comprises at least two optical sensors 113, for example a first optical sensor 118 and a second optical sensor 120, each having at least one light-sensitive area 121. The optical detector 110, further, comprises at least one transfer device 128, such as at least one lens or a lens system, specifically for beam
10 shaping. The transfer device 128 has an optical axis 129, wherein the transfer device 128 and the optical detector preferably may have a common optical axis. The detector 110 may comprise at least one illumination source 136. The illumination source 136, as an example, may comprise a laser source. The illumination source 136 may be arranged such that the illumination light beam 138 is one or both of non-parallel to the optical axis 126, but off-axis, or shifted
15 from the optical axis 126. The illumination source 136 may be configured for generating at least one illumination light beam 138 for illuminating the object 112. The illumination light beam 138 is fully or partially reflected by the object 112 and travels back towards the detector 110, thereby forming the light beam 116. The light beam 116 propagates from the object 112 towards the first optical sensor 118 and the second optical sensor 120. The first optical sensor 118 may com-
20 prise a first light-sensitive area 122, and the second optical sensor 120 may comprise a second light-sensitive area 124. In this embodiment the optical sensors 118, 120 may be arranged such that the light-sensitive areas 122, 124 have identical surface areas. For example, the optical sensors 118, 120 may be identical. The detector 110 may further comprise the reflective element 140, such as at least one beam splitter, which is adapted to lead the light beam 116 from
25 the transfer device 128 to both of the optical sensors 118, 120. The first optical sensor 118 may have a distance db_1 from the beam splitter and the second optical sensor 120 may have a distance db_2 from the beam splitter, wherein $db_1 \neq db_2$. Again, an evaluation device 132 may be used, having, e.g., at least one divider 142 for forming the quotient signal Q, and, as an example, at least one position evaluation device 144, for deriving the at least one longitudinal coordi-
30 nate z from the quotient signal Q. It shall be noted that the evaluation device 132 may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 142, 144 may be embodied by appropriate software components.

In Figure 27 B, the detector 110 comprises at least two optical sensors 113, for example a first
35 optical sensor 118 and a second optical sensor 120, each having at least one light-sensitive area 121. The optical detector 110, further, may comprise at least one transfer device 128, such as at least one lens or a lens system. The transfer device 128 has an optical axis 129, wherein the transfer device 128 and the optical detector preferably may have a common optical axis. The detector 110 may comprise at least one illumination source 136. The illumination source
40 136, as an example, may comprise a laser source, for example with a 1550nm laser source. The illumination source 136 may be arranged such that the illumination light beam 138 is one or both of non-parallel to the optical axis 126, but off-axis, or shifted from the optical axis 126. The illumination source 136 may be configured for generating at least one illumination light beam

138 for illuminating the object 112. The illumination light beam 138 is fully or partially reflected by the object 112 and travels back towards the detector 110, thereby forming the light beam 116. The light beam 116 propagates from the object 112 towards the first optical sensor 118 and the second optical sensor 120. The first optical sensor 118 may comprise the first light-sensitive area 122, and the second optical sensor 120 may comprise the second light-sensitive area 124. As can be seen in Fig. 27B, the first optical sensor 118 is a small optical sensor, whereas the second optical sensor 120 is a large optical sensor. The optical sensors 118, 120 may be Ge-sensors. The first optical sensor 118 may have a first distance from the transfer device 128 and the second optical sensor 120 may have a second distance from the transfer device 128. In Figure 27B, the first optical sensor 118 may be close to the transfer device 128, whereas the second optical sensor 120 may be arranged further away in direction to the focus. The first optical sensor 118 may be arranged such that, independent from a distance from the object, a sensor signal of the first optical sensor 118 may be proportional to the total power of the light beam passing the transfer device 128. Again, an evaluation device 132 may be used, having, e.g., at least one divider 142 for forming the quotient signal Q , and, as an example, at least one position evaluation device 144, for deriving the at least one longitudinal coordinate z from the quotient signal Q . It shall be noted that the evaluation device 132 may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 142, 144 may be embodied by appropriate software components.

In Figure 28 experimental results of a distance determination with the detector 110 is shown. In this experimental setup, the transfer device 128 was a plano-convex lens having a focal length of 150 mm, a diameter of 75 mm and coated with an anti-reflective coating for a range of 1050-1700 nm, available as Thorlabs LA1002-C. The object 112, in this case a piece of carpet, was illuminated by a laser diode with 30mW CW-power output at a wavelength of 1550 nm, available as Schäfter+Kirchhoff 55cm-1550-30-Q04-T12-C-6. The illumination source 136 was placed laterally next to the transfer device and was operated at 367Hz with a 50:50 rectangle modulation. A second optical sensor 120, in this experimental setup, a Ge photodiode with dimensions of 10mm x 10mm, available as Thorlabs FDG1010, was arranged directly on the transfer device, and a first optical sensor 118 having a diameter of 5mm, available as Thorlabs FDG05 was placed with a distance of 0,85m from the transfer device 128. Figure 28 shows a dependency of distance d in m, corresponding to the longitudinal coordinate z of the object, of the determined quotient signal Q .

In Figure 29, a further exemplary embodiment of the detector 110 is depicted. For details of the optical sensor 113 reference is made to Figure 6 above. As in Figures 27A and B, the illumination source 136 may be positioned off-axis. The illumination source 136 may be adapted to generate and/or to project a cloud of points, for example the illumination source 136 may comprise one optical element 194, in particular one or more optical elements selected from the group consisting of at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The sensor element 115 may comprise a matrix 117 of optical sensors 113, each optical sensor 113 having at least one light-

sensitive area 121 facing the object 112. The sensor element 115 may comprise at least one CMOS sensor. In Figure 30, schematically the cloud of points impinging on the sensor element 115 is depicted. Additionally, disturbances may be present on the matrix 117 such as disturbances due to speckles and/or extraneous light and/or multiple reflections. The evaluation device 132 may be adapted to determine at least one region of interest 196, for example one or more pixels illuminated by the light beam 116 which are used for determination of the longitudinal coordinate of the object 112. In Figure 30, regions of interest 196 are shown exemplary as circular areas with dashed lines. For example, the evaluation device 132 may be adapted to perform a filtering method, for example, a blob-analysis and/or object recognition method.

Figure 31 A to O show further exemplary configurations of optical sensors according to the present invention, in particular top view in direction of propagation of the light beam 116. In Figure 31A, a top view of two rectangular optical sensors 113 is shown, wherein the first optical sensor 118 is a small optical sensor in front of a larger second optical sensor 120. The first optical sensor 118 and the second optical sensor 120 may be arranged with a different offset, in particular in a transversal direction y , from the optical axis 126. In Figures 31B and 31C, top view of a large rectangular optical sensor 120 is shown, wherein the first optical sensor 118 is a small optical sensor in front of a larger second optical sensor 120 having a triangle shaped (Figure 31B) or star-shaped (Figure 31C) light-sensitive area 121. In Figures 31 M to O, a top view of two rectangular optical sensors 113 is shown, wherein the first optical sensor 118 and the second optical sensor 120 are rectangular sensors with the same size. In Figures 31 M to O a mask 119 is arranged in front of the first and second optical sensors 118, 120. The mask 119 may be arranged with a different offset from the optical axis 126. The mask 119 may have an arbitrary size and shape, for example, the mask may be rectangular shaped (Figure 31M), triangle shaped (Figure 31N) or star-shaped (Figure 31O). However, other sizes and shapes are feasible. Mask 119 may be adapted to prevent light impinging on the light sensitive areas of the first and second optical sensors 118, 120. If used in a situation comparable to the situation illustrated in Figure 19A, the mask may result in a further z -dependent decrease of a decreasing sensor signal, resulting in an increased z -dependency of the resulting quotient signal Q .

The first optical sensor 118 and the second optical sensor 120 may be arranged with a different offset from the optical axis 126. Figure 31K shows two circular shaped optical sensors 113, wherein the first optical sensor 118 is a small optical sensor in front of the larger second optical sensor 120. In Figures 31D, the light sensitive area of the first optical sensor 118 is square-shaped, and the light sensitive area of the second optical sensor 120 is rectangular, such that the surface areas in x and y differ. In addition, a center of the first optical sensor 118 and a center of second optical sensor 120 may have different x coordinates such that the optical sensors 118, 120 may have different spatial offset in one or more of x and y direction from the optical axis. In Figure 31H, both the first optical sensor 118 and the second optical sensor 120 may be rectangular. The first optical sensor 118 and the second optical sensor 120 may be arranged such that the center of the first optical sensor 118 and the center of second optical sensor 120 may have different x coordinates and that the surface areas in x and y differ. The first optical sensor 118 and the second optical sensor 120 may be arranged with a different offset from the

optical axis 126. In Figure 31L, the first optical sensor 118 may have a deviating shape from the shape of the second optical sensor 120 such as a circular or semicircular shape. Figures 31 E, F, G, I, J show sensor element 115 having the matrix of pixels 117. In Figures 31 E, F, G the sensor element 115 has a rectangular shape, whereas in Figures 31 I and J the sensor element
 5 115 has a circular shape. Rows and columns may be arranged equidistant or non-equidistant. In case of equidistant rows and/or columns the sensor element 115 may be arranged with a spatial offset to the optical axis 126.

Figure 32 shows experimental results of a determination of a longitudinal coordinate z for different object sizes. The experimental setup was comparable to the setup shown in Figure 19A. In
 10 the measurement setup the object 112, a paper target, was illuminated by laser 136 with a wavelength of 905 nm, 1,6 mW and modulated with 23 Hz. Light reflected from the object 112 was led to a quadrant diode 178, available as OSI Optoelectronics, OSI Spot-4D. Between the object 112 and quadrant diode 178 a lens 128 having an aspherical effective focal length of
 15 20,0 mm, a diameter of 25,0 mm was placed, available as Thorlabs AL2520M-B. A distance from quadrant diode 178 to lens 128 was 19,7 mm and the quadrant diode 178 had an offset from the optical axis in $y = 0,5$ mm. Further, different from the situation in Figure 19A and not shown in Fig. 19A, in the situation of Figure 32, an iris diaphragm or a further lens was placed in front of the laser 136 between the laser 136 and the object 112, to modify the illumination light
 20 beam 138. The iris diaphragm was used to modify the width of the illumination light beam 138. The further lens was used to obtain a diverging illumination light beam 138 with a beam width decreasing with the distance from the laser 136. Figure 32 shows the quotient Q of two adjacent quadrant currents as a function of the distance, i.e. longitudinal coordinate of the object 112, z in mm. In a first experiment, a diameter of a illumination light beam 138 was varied by an iris
 25 diaphragm from 1 mm, solid line, to 3,5 mm, loosely dashed line, and to 5 mm, dash-dot line. In a second experiment, the diameter of the illumination light beam 138 was varied by the further lens such that the beam width of the illumination light beam 138 diverges with increasing distance from the further lens. To characterize the diverging illumination light beam 138, the beam width at 1m, 2m, and 3m from the lens 128 is given. The dashed line shows the quotient Q , wherein the beam width was 10 mm at 1 m distance, 16 mm at 2 m distance and 22 mm at 3 m
 30 distance from the lens 128. The dotted line shows the quotient Q , wherein the beam width was 15 mm at 1 m distance, 32 mm at 2 m distance and 49 mm at 3 m distance from the lens 128. Below $z = 2300$ mm all curves show the same dependency of Q from z and deviations below ± 5 % and thus independence from the beam width. In the situation of Figure 32 the beam width at the object 112 corresponds to the object size that is measured. The independence of the
 35 quotient Q from the beam width and thus from the object size clearly demonstrates the property of object size independence. In an application, the influence of the further lens leading to a diverging illumination light beam may be caused by a liquid drop, or rain, or dirt or the like such as on the laser module. Thus, object size independence is an important property for robust meas-
 40 urements.

Figures 33A and B show an exemplary beam profile and determination of first area 198 and second area 200 of the beam profile. In Figure 33A normalized intensity I_{norm} as a function of the

transversal coordinate x in mm is depicted. The object size was 20mm and the distance object to sensor was 1200mm. The first area 198 of the beam profile may comprise essentially edge information of the beam profile and the second area 200 of the beam profile may comprise essentially center information of the beam profile. The beam profile may have a center, a maximum value of the beam profile and/or a center point of a plateau of the beam profile. In Figure 33A the center of the plateau may be at 500mm. The beam profile may further comprise falling edges extending from the plateau. The second area 200 may comprise inner regions of the cross section and the first area 198 may comprise outer regions of the cross section. At least one area of the beam profile may be determined and/or selected as first area 198 of the beam profile if it comprises at least parts of the falling edges of the cross section. In Figure 33A, the first area 198 at both sides from the center is depicted in dark grey. At least one area of the beam profile may be determined and/or selected as second area 200 of the beam profile if it is close or around the center and comprises essentially center information. In Figure 33A, the second area 200 is depicted in light grey. Figure 33B shows the corresponding light spot of the intensity distribution as shown in Figure 33A and the corresponding first area 198, and second area 200.

Figure 34 shows a further exemplary embodiment of the detector 110. The optical sensors 113 may comprise the first optical sensor 118 having the first light sensitive area 122 and the second optical sensor 120 having the second light sensitive area 124. The first light sensitive area 122 and the second light sensitive area 124 are arranged such that a condition

$$\frac{a}{c} \neq \frac{b}{d}$$

is satisfied. "a" is a ratio of photons hitting both an inner region 202 of a plane 204 perpendicular to the optical axis 126 intersecting the optical axis 126 at a distance equal to half of a focal length f of the transfer device 128 and the first light sensitive area 122. "b" is a ratio of photons hitting both the inner region 202 of the plane 204 and the second light sensitive area 124. "c" is a ratio of photons hitting both an outer region 206 of the plane 204 and the first light-sensitive area 122. "d" is a ratio of the photons hitting both the outer region 206 of the plane 204 and the second light sensitive area 124. The inner region 202 may have an area with a geometrical center point on the optical axis 126 and an extension such that half of the photons hit the plane 204 within the inner region 202 and the other half hit the plane outside the inner region 202. The inner region 202 may be designed as a circle with a center point on the optical axis 126 and a radius r which is chosen such that half of the photons hit the plane 204 within the circle and the other half hit the plane outside the circle.

In Fig. 25, a schematic view of an exemplary embodiment of a detector 2110 for determining a position of at least one object 2112 is depicted. In Figure 35, the object 2112 is depicted for two different object distances. The detector 2110 comprises at least two optical sensors 2113, for example a first optical sensor 2118 and a second optical sensor 2120, each having at least one light-sensitive area 2121. The object 2112 may comprise at least one beacon device 2114, from which a light beam 2116, also denoted as incident light beam, propagates towards the detector 2110. Additionally or alternatively, the detector may comprise at least one illumination source 2115 for illuminating the object 2112. As an example, the illumination source 2115 may be con-

figured for generating an illuminating light beam for illuminating the object 2112. Specifically, the illumination source 2115 may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The illumination source 2115 may
5 comprise an artificial illumination source, in particular at least one laser source and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. As an example, the light emitted by the illumination source 2115 may have a wavelength of 300-500 nm. Additionally or alternatively, light in the infrared spectral range may be used, such as in the
10 range of 780 nm to 3.0 μm . Specifically, the light in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm may be used. Further, the illumination source 2115 may be configured for emitting modulated or non-modulated light. In case a plurality of illumination sources 2115 is used, the different illumination sources may have different modulation frequencies which, as outlined in further detail below,
15 later on may be used for distinguishing the light beams.

The first optical sensor 2118 may comprise a first light-sensitive area 2122, and the second optical sensor 2120 may comprise a second light-sensitive area 2124. The light beam 2116, as an example, may propagate along an optical axis 2126 of the detector 2110. Other embodiments,
20 however, are feasible. The first light-sensitive area 2122 and the second light-sensitive area may be oriented towards the object 2112. The optical detector 2110, further, may comprise at least one transfer device 2128, such as at least one lens or a lens system, specifically for beam shaping. The transfer device 2128 may have at least one focal length in response to the incident light beam 2116 propagating from the object 2112 to the detector 2110. The transfer device 2128 may have an optical axis 2129, wherein the transfer device 2128 and the optical detector preferably may have a common optical axis. The transfer device 2128 may constitute a coordinate system. A direction parallel or anti-parallel to the optical axis 2126, 2129 may be defined as a longitudinal direction, whereas directions perpendicular to the optical axis 2126, 2129 may be defined as transversal directions, wherein a longitudinal coordinate l is a coordinate along the optical axis 2126, 2129 and wherein d is a spatial offset from the optical axis 2126, 2129. Consequently, the light beam 2116 is focused, such as in one or more focal points, and a beam width of the light beam 2116 may depend on a longitudinal coordinate z of the object 2112, such as on a distance between the detector 2110 and the beacon device 2114 and/or the object 2112. The optical sensors 2118, 2120 may be positioned off focus. For details of this
30 beam width dependency on the longitudinal coordinate, reference may be made to one or more of the WO 2012/110924 A1 and/or WO 2014/097181 A1.

The detector comprises at least one angle dependent optical element 2130 adapted to generate at least one light beam 2131 having at least one beam profile depending on an angle of incidence of an incident light beam propagating from the object 2112 towards the detector 2110 and illuminating the angle dependent optical element 2130. The angle dependent optical element 2130 may have angle dependent transmission properties such that an electromagnetic wave impinging on a first side 2132, for example a surface and/or an entrance, of the angle de-
40

pendent optical element 2130 may be partly, depending on the properties of the angle dependent optical element, absorbed and/or reflected and/or transmitted. A degree of transmission may be defined as quotient of transmitted power of the electromagnetic wave, i.e. the power behind the angle dependent optical element 2130, and the incident power of the electromagnetic wave, i.e. the power before impinging on the angle dependent optical element 2130. The angle dependent optical element 2130 may be designed such that the degree of transmission depends on an angle of incidence at which the incident light beam propagating from the object towards the detector 2116 impinges on the angle dependent optical element 2130. The angle of incident may be measured with respect to an optical axis of the angle dependent optical element 2130.

The angle dependent optical element 2130 may be arranged in the direction of propagation behind the transfer device 2128. The transfer device may, for example, comprise at least one collimating lens. The angle dependent optical element 2130 may be designed to weaken rays impinging with larger angles compared to rays impinging with a smaller angle. For example, the degree of transmission may be highest for light rays parallel to the optical axis, i.e. at 0° , and may decrease for higher angles. In particular, at at least one cut-off angle the degree of transmission may steeply fall to zero. Thus, light rays having a large angle of incidence may be cut-off.

The angle dependent optical element 2130 may comprise at least one optical element selected from the group consisting of: at least one optical fiber, in particular at least one multifurcated optical fiber, in particular at least one bifurcated optical fiber; at least one diffractive optical element; at least one angle dependent reflective element, at least one diffractive grating element, in particular a blaze grating element; at least one aperture stop; at least one prism; at least one lens; at least one lens array, in particular at least one microlens array; at least one optical filter; at least one polarization filter; at least one bandpass filter; at least one liquid crystal filter, in particular a liquid crystal tunable filter; at least one short-pass filter; at least one long-pass filter; at least one notch filter; at least one interference filter; at least one transmission grating; at least one nonlinear optical element, in particular one birefringent optical element.

The first optical sensor 2118, in response to the illumination by the light beam 2131, may generate a first sensor signal s_1 , whereas the second optical sensor 2120 may generate a second sensor signal s_2 . Preferably, the optical sensors 2118, 2120 are linear optical sensors, i.e. the sensor signals s_1 and s_2 each are solely dependent on the total power of the light beam 131 or of the portion of the light beam 2131 illuminating their respective light-sensitive areas 2122, 2124, whereas these sensor signals s_1 and s_2 are independent from the actual size of the light spot of illumination.

The sensor signals s_1 and s_2 are provided to an evaluation device 2133 of the detector 2110. The evaluation device 2133 is embodied to derive a quotient signal Q , as explained above.

From the quotient signal Q , derived by dividing the sensor signals s_1 and s_2 or multiples or linear combinations thereof, may be used for deriving at least one item of information on a longitudinal coordinate z of the object 2112 and/or the beacon device 2114, from which the light beam 2116 propagates towards the detector 2110. The evaluation device 2133 may have at least one di-

vider 2134 for forming the combined signal Q, and, as an example, at least one position evaluation device 2136, for deriving the at least one longitudinal coordinate z from the combined signal Q. It shall be noted that the evaluation device 2133 may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 2134, 2136 may be embodied by appropriate software components.

In Fig. 36, a modification of the embodiment of Fig. 35 is shown, which forms an alternative detector 2110. The alternative embodiment of the detector 2110 widely corresponds to the embodiment shown in Fig. 35. In Figure 36, the angle dependent optical element 2130 may comprise at least one optical fiber 2138. The optical fiber 2138 may be adapted to transmit at least parts of incident light beam 2116 which are not absorbed and/or reflected, between two ends of the optical fiber. The optical fiber 2138 may have a length and may be adapted to permit transmission over a distance. The optical fiber 2138 may comprise at least one fiber core which is surrounded by at least one fiber cladding having a lower index of refraction as the fiber core. Below the angle of acceptance, the optical fiber 2138 may be adapted to guide the incoming light beam by total internal reflection.

The optical fiber 2138 may be designed such that the degree of transmission may be highest for incoming light rays parallel, i.e. at an angle of 0° , to the optical fiber, neglecting reflection effects. The optical fiber 2130 may be designed such that for higher angles, for example angles from 1° to 10° , the degree of transmission may decrease smoothly to around 80% of the degree of transmission for parallel light rays and may remain at this level constantly up to an acceptance angle of the optical fiber 2138. The optical fiber 2138 may be designed such that above the acceptance angle total reflection within the optical fiber 2138 is not possible such that the light rays are reflected out of the optical fiber 2138. The optical fiber 2138 may be designed that at the acceptance angle, the degree of transmission may steeply fall to zero. Light rays having a large angle of incidence may be cut-off.

As shown in Figure 36, the illumination source 2115 may be adapted to illuminate the object 2112 through the angle dependent optical element 2130. The optical fiber 2138 may comprise at least one illumination fiber 2140 adapted to transmit the light beam 2142 generated by the illumination source 2115 such that it illuminates the object 2112. The illumination source 2115 may be adapted to couple the at least one light beam 2142 generated by the illumination source 2115 into the illumination fiber 2140.

The optical fiber 2138 may comprise at least two or more fibers. The optical fiber 2138 may be at least one multifurcated optical fiber, in particular at least one bifurcated optical fiber. In the embodiment of Figure 36, and as shown in the cut through in Figure 37, the optical fiber 2138 may comprise four fibers. In particular the optical fiber may comprise the illumination fiber 2138 and at least two fibers each for generating at least one light beam 2131, denoted as first fiber 2144 and second fiber 2146. As shown in Figure 37, the first fiber 2144 and the second fiber 2146 may be arranged close to each other at an entrance end 2148 of the optical fiber 2138 and may split into legs separated by a distance at an exit end 2150 of the optical fiber 2138.

The first fiber 2144 and second fiber 2146 may be designed as fibers having identical properties or may be fibers of different type. The first fiber 2144 may be adapted to generate at least one first light beam 2152 and the second fiber 2146 may be adapted to generate at least one second light beam 2154. The optical fiber 138 may be arranged such that the incident light beam 2116 may impinge at a first angle of incidence into the first fiber 2144 and at a second angle of incidence, different from the first angle, into the second fiber 2146, such that the degree of transmission is different for the first light beam 2152 and the second light beam 2154. One of the optical sensors 2113 may be arranged at an exit end of the first fiber 2144 and the other optical sensor 2113 may be arranged at an exit end of the second fiber 2146. The optical fiber may comprise more than three fibers, for example four fibers as depicted in Figure 37.

It shall further be noted that the embodiments shown in Fig. 35 and 36 simply provide embodiments for determining the longitudinal coordinate z of the object 2112. It is also feasible, however, to modify the setups of Fig. 35 and 36 to provide additional information on a transversal coordinate of the object 2112 and/or of parts thereof. As an example, e.g. in between the transfer device 2128 and the optical sensors 2118, 2120, one or more parts of the light beam 2116 may be branched off, and may be guided to a position-sensitive device such as one or more CCD and/or CMOS pixelated sensors and/or quadrant detectors and/or other position sensitive devices, which, from a transversal position of a light spot generated thereon, may derive a transversal coordinate of the object 2112 and/or of parts thereof. The transversal coordinate may be used to verify and/or enhance the quality of the distance information. For further details, as an example, reference may be made to one or more of the above-mentioned prior art documents which provide for potential solutions of transversal sensors.

Figures 38 visualizes angle dependent transmission of an angle dependent optical element 2130. The angle dependent optical element 2130 may be designed such that the degree of transmission depends on an angle of incidence at which the incident light beam propagating from the object towards the detector 2116 impinges on the angle dependent optical element 2130. The angle dependent optical element 2130 may be designed to weaken rays impinging with larger angles compared to rays impinging with a smaller angle. In particular, at the cutoff angle the degree of transmission may steeply fall to zero and the light rays having a large angle of incidence may be cut-off. As shown in Figure 38 regions of the incident light beam 2116 are cut-off by the angle dependent optical element 2130 in the generated light beam 2131.

Figure 39 shows a dependency of the transmission power P in W of the optical fiber at constant irradiated power as a function of angle of incidence A in degree. The acceptance angle is shown as vertical line. The degree of transmission may be highest for incoming light rays parallel, i.e. at an angle of 0° , to the optical fiber, neglecting reflection effects. For higher angles, for example angles from 1° to 10° , the degree of transmission may decrease smoothly to around 80% of the degree of transmission for parallel light rays and may remain at this level constantly up to an acceptance angle of the optical fiber 2138. At the acceptance angle, the degree of transmission may steeply fall to zero. Light rays having a large angle of incidence may be cut-off.

Figures 40A and 40B show experimental results of distance measurements. In The determined distance z_{meas} in mm is shown as a function of the object distance z_{obj} in mm. As illumination source 115 a Laser was used having a wavelength of 980 nm and average power of 2,4 mW available under Flexpoint® Laser components module. Two Si-photodetectors were used as optical sensors 113. As optical fiber 2138 and transfer device 2128 available under Thorlabs Fixed Focus Collimation package F220SMA-980 was used. In Figure 40A, the solid line indicates where $z_{\text{meas}} = z_{\text{obj}}$. For the measurement the object distance was varied and two different types of object were used, in particular a black paper object, curve 2156 (dotted line), and a white paper object, curve 2158 (dashed line). The determined object distance is in agreement with the real distance within 2% for small and medium distances and within 10% for large distances. In Figure 40B, the combined signal Q determined by dividing the signals of the two photodetectors as a function of the distance z_{obj} in mm is shown for the black paper object (dotted line) and the white paper object (dashed line). The determined quotient for both object types is in agreement within 2% for small and medium distances and within 10% for large distances.

Figure 41 shows, in a highly schematic illustration, an exemplary embodiment of a detector 2110, for example according to the embodiments shown in Figure 35 or 36. The detector 2110 specifically may be embodied as a camera 2156 and/or may be part of a camera 2156. The camera 156 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible.

Fig. 41 further shows an embodiment of a detector system 2158, which, besides the at least one detector 2110, comprises one or more beacon devices 2114, which, in this example, may be attached and/or integrated into an object 2112, the position of which shall be detected by using the detector 2110. Fig. 41 further shows an exemplary embodiment of a human-machine interface 2160, which comprises the at least one detector system 2158 and, further, an entertainment device 2162, which comprises the human-machine interface 2160. The figure further shows an embodiment of a tracking system 2164 for tracking a position of the object 2112, which comprises the detector system 2158. The components of the devices and systems shall be explained in further detail below.

Fig. 41 further shows an exemplary embodiment of a scanning system 2166 for scanning a scenery comprising the object 2112, such as for scanning the object 2112 and/or for determining at least one position of the at least one object 2112. The scanning system 2166 comprises the at least one detector 2110, and, further, optionally, the at least one illumination source 2115 as well as, optionally, at least one further illumination source 2115. The illumination source 2115, generally, is configured to emit at least one illumination light beam 2142, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 2114 and/or on a surface of the object 2112. The scanning system 2166 may be designed to generate a profile of the scenery including the object 2112 and/or a profile of the object 2112, and/or may be designed to generate at least one item of information about the dis-

tance between the at least one dot and the scanning system 2166, specifically the detector 2110, by using the at least one detector 2110.

As outlined above, an exemplary embodiment of the detector 2110 which may be used in the setup of Fig. 41 is shown in Fig. 35 and 36. Thus, the detector 2110, besides the optical sensors 2118, 2120, comprises at least one evaluation device 2133, having e.g. the at least one divider 2134 and/or the at least one position evaluation device 2136, as symbolically depicted in Fig. 41. The components of the evaluation device 2133 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 2110. Besides the possibility of fully or partially combining two or more components, one or more of the optical sensors 2118, 2120 and one or more of the components of the evaluation device 2133 may be interconnected by one or more connectors 2168 and/or by one or more interfaces, as symbolically depicted in Fig. 41. Further, the one or more connectors 2168 may comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 2168, the evaluation device 2133 may fully or partially be integrated into one or both of the optical sensors 2118, 2120 and/or into a housing 2170 of the detector 2110. Additionally or alternatively, the evaluation device 2133 may fully or partially be designed as a separate device.

In this exemplary embodiment, the object 2112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 2172, the position of which may be manipulated by a user 2174. As an example, the object 2112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 2112 are possible. Further, the user 2174 himself or herself may be considered as the object 2112, the position of which shall be detected.

As outlined above, the detector 2110 comprises at least the optical sensors 2118, 2120. The optical sensors 2118, 2120 may be located inside the housing 2170 of the detector 2110. Further, the at least one transfer device 2128 is comprised, such as one or more optical systems, preferably comprising one or more lenses.

An opening 2176 inside the housing 2170, which, preferably, is located concentrically with regard to the optical axis 2126 of the detector 2110, preferably defines a direction of view 2178 of the detector 2110. A coordinate system 2180 may be defined, in which a direction parallel or anti-parallel to the optical axis 2126 may be defined as a longitudinal direction, whereas directions perpendicular to the optical axis 126 may be defined as transversal directions. In the coordinate system 2180, symbolically depicted in Fig. 41, a longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other types of coordinate systems 2180 are feasible, such as non-Cartesian coordinate systems.

The detector 2110 may comprise the optical sensors 2118, 2120 as well as, optionally, further optical sensors. The optical sensors 2118, 2120 may be located in one and the same beam

path, for example one behind the other, such that the first optical sensor 2118 covers a portion of the second optical sensor 2120. Alternatively, however, a branched beam path may be possible, for example using a multifurcated optical fiber. The branched beam path may comprise additional optical sensors in one or more additional beam paths, such as by branching off a beam path for at least one transversal detector or transversal sensor for determining transversal coordinates of the object 2112 and/or of parts thereof. Alternatively, however, the optical sensors 2118, 2120 may be located at the same longitudinal coordinate.

One or more light beams 2116 are propagating from the object 2112 and/or from one or more of the beacon devices 2114, towards the detector 2110. The detector 2110 is configured for determining a position of the at least one object 2112. For this purpose, as explained above in the context of Fig. 35 to 40, the evaluation device 2133 is configured to evaluate sensor signals provided by the optical sensors 2118, 2120. The detector 2110 is adapted to determine a position of the object 2112, and the optical sensors 2118, 2120 are adapted to detect the light beam 2131. In case no illumination source 2115 is used, the beacon devices 2114 and/or at least one of these beacon devices 2114 may be or may comprise active beacon devices with an integrated illumination source such as a light-emitting diode. In case the illumination source 2115 is used, the beacon devices 2114 do not necessarily have to be active beacon devices. Contrarily, a reflective surface of the object 2112 may be used, such as integrated reflected beacon devices 2114 having at least one reflective surface such as a mirror, retro reflector, reflective film, or the like. The light beam 2116, directly and/or after being modified by the transfer device 2128, such as being focused by one or more lenses, impinges on the angle dependent element 2130 which generates the at least one light beam which illuminates the light-sensitive areas 2122, 2124 of the optical sensors 2118, 2120. For details of the evaluation, reference may be made to Fig. 35 to 40 above.

As outlined above, the determination of the position of the object 2112 and/or a part thereof by using the detector 2110 may be used for providing a human-machine interface 2160, in order to provide at least one item of information to a machine 2182. In the embodiments schematically depicted in Fig. 41, the machine 2182 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 2133 may even be fully or partially integrated into the machine 2182, such as into the computer.

As outlined above, Fig. 41 also depicts an example of a tracking system 2164, configured for tracking the position of the at least one object 2112 and/or of parts thereof. The tracking system 2164 comprises the detector 2110 and at least one track controller 2184. The track controller 2184 may be adapted to track a series of positions of the object 2112 at specific points in time. The track controller 2184 may be an independent device and/or may be fully or partially integrated into the machine 2182, specifically the computer, as indicated in Fig. 41 and/or into the evaluation device 2133.

Similarly, as outlined above, the human-machine interface 2160 may form part of an entertainment device 2162. The machine 2182, specifically the computer, may also form part of the en-

entertainment device 2162. Thus, by means of the user 2174 functioning as the object 2112 and/or by means of the user 2174 handling a control device 2172 functioning as the object 2112, the user 2174 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer.

Referring to Figure 42, the detector 110, 1110, 2110, such as the detector as described with respect to Figures 1 to 41 may be adapted to determine depth information, in particular absolute depth information, from a radiance ratio of at least two asymmetric regions of a light beam profile on the at least two optical sensors 113, 1118, 1120, 2113. For example, the detector 110, 1110, 2110 may comprise a plurality of optical sensors arranged in the matrix 117. The detector 110, 1110, 2110 may be adapted to determine depth information from a radiance ratio of at least two asymmetric regions within an enclosed, in particular, defocused beam profile captured by a single matrix of optical sensors such as a CMOS detector. In particular, the detector 110, 1110, 2110 may be adapted to determine the depth information using the radiance ratio independent of a certain object size range. As outlined above, this principle is called Distance by Photon Ratio (DPR). In one embodiment, the light beam 116, 1116 may illuminate the sensor element with at least one pattern comprising at least one feature point. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. The evaluation device 132 may be configured for deriving the quotient signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A1 and A2 are areas of the beam profile at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors. The central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

In the embodiment shown in Figure 42, the light beam 116, 1116 propagating from the object 112, 1112 to the detector 110, 1110, 2110 may illuminate the matrix 117 with at least one line pattern 2186. The line pattern 2186 may be generated by the object 112, 1112, for example in response to an illumination by the at least one illumination source 136 with an illumination pattern comprising at least one illumination line pattern. A1 may correspond to an area with a full line width of the line pattern 2186 in the matrix 117. The line pattern 2186 in the matrix 117 may be widened and/or displaced compared to the line pattern of the illumination pattern such that a

line width in the matrix 117 is increased. In particular, the line width of the line pattern 2186 in the matrix 117 may change from one column to another column. A2 may be a central area of the line pattern 2186 in the matrix 117. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern 2186 may be segmented in the matrix 117. Each of the columns may comprise center information of intensity in the central area of the line pattern 2186 and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern 2186.

Figure 43 shows a simulation testing of object size independence for a one-dimensional case using computational ray tracing. In a simulation testing, an aspheric lens with $f=10$ mm, 10 mm pupil diameter in a distance range of 100 mm to 600 mm was used. Using this specification, object size independence of about 10 mm was obtained, such that the spot size was varied from 1 mm to 25 mm. In Fig. 43, the quotient $Q(z)$ over the longitudinal coordinate z is shown for 1 mm variation (curve 2188), 2 mm variation (curve 2190), 5 mm variation (curve 2192), 15 mm variation (curve 2194), 20 mm variation (curve 2196) and 25 mm variation (curve 2198). It can be seen that the quotient for object sizes above 10 mm deviates, whereas that of object sizes smaller than 10 mm yield identical ratios. This feature reduces calibration efforts for targets of varying size and is inherent to DPR analysis.

Referring to Figures 44A and B, as outlined above, the detector 110, 1110, 2110 may comprise the at least one matrix 117 of optical sensors 113, 1118, 1120, 2113. With the aid of such a pixelated imaging device, a defocused beam profile may be subdivided into cross-sections along lines of a certain angle θ and with a distance ω from the origin of ordinates as shown in Figure 44A. Accordingly, the parameterization of a single line would be given by $\omega = x \cos(\theta) + y \sin(\theta)$. The integration of the intensity along parallel lines can be mathematically described by an integral projection $\Re\{\cdot\}$ of the well-known Radon transform which reads

$$\Re_{(\omega,\theta)}\{f(x,y)\} = \iint_{-\infty}^{\infty} f(x,y) \delta(x \cos(\theta) + y \sin(\theta) - \omega) dx dy$$

where δ denotes the Dirac delta function and $f(x,y)$ is the intensity of an enclosed defocused beam profile. The photon ratio R for a given angle θ and projection width ω is then given by

$$R = \frac{\Re_{(\omega,\theta)}\{f'(x,y)\}}{\Re_{(\omega,\theta)}\{f(x,y)\}}$$

with $f'(x,y)$ as the overshined image region highlighted in Fig. 44B. It is expected that the variation of θ yields different ratios R for skewed object surfaces. It may be sufficient to let θ vary in the following interval $\{\theta \in \mathbb{R}_+, \theta < \pi\}$.

Figures 45A and B show further embodiments of the detector 110 according to the present invention comprising at least one bi-cell. The illumination source 136, such as a laser source, may generate the light beam 138 illuminating object 112. The reflected light beam 116 may propagate from the object 112 to the transfer device 128 and may impinge on the bi-cell of optical

sensors 176. In Figure 45A a side view is shown and in Figure 45B a front view is shown. The detector 110 may comprise at least one FiP sensor adapted for generating the so called FiP effect as described in WO 2015/024871 or WO2016/120392. For example, the bi-cell in Figures 45 A and B may be adapted to generate a so called FiP signal. As outlined e.g. in WO 2015/024871 or WO2016/120392, the FiP signal can be used to determine depth information over a wide distance range. The FiP sensor may be adapted to exhibit a positive and/or a negative FiP effect. The negative FiP effect may be used to tune small image effects at high distances. Image changes such as position, size, shape, sharpness, etc. may vanish at high distances while the negative FiP effect increases. Furthermore, no luminance dependence may be introduced since both cells are at the same longitudinal position and thus receive identical photon density.

Figure 46 shows experimental results, in particular spot diameter independence and luminance independence of the combined sensor signal, determined using the detector setup shown in Figure 46. In particular, the bi-cell was a PbS-Bi-cell and a 1550 nm laser was used with a laser spot size of 4 mm. The baseline was 12.5 mm. The transfer device was a Thorlabs Asphere lens with focal length of $f = 20$ mm and diameter of $D = 25$ mm. Figure 46 shows quotient Q over the longitudinal coordinate z for different luminance and spot diameter, in particular for luminance of 2.6 mW and spot diameter of 12 mm (curve 2200), 2.4 mW and 6 mm (curve 2202) and 1.2 mW and spot diameter of 3 mm (curve 2204). All curves show identical curve shape and thus, spot diameter independence.

Figures 47A to C show three embodiments of a hexagonal illumination pattern. The illumination source 136 may be adapted to generate at least one illumination pattern for illuminating the object 112. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. Specifically, the illumination source 136 may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The illumination pattern may comprise at least one feature such as a point or symbol. The illumination pattern may comprise a plurality of features. The illumination pattern may comprise an arrangement of periodic or non-periodic features. The illumination pattern may be generated by ambient light, such as by at least one ambient light source, or by the at least one illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern, a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one quasi-periodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines. For example, the illumination source may be adapted to generate and/or to project a cloud of points. The illumination pattern may comprise regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern, or a pattern comprising further convex tilings. The illumination pattern may comprise as much as

possible features per area such that hexagonal pattern may be preferred. A distance between two features of the illumination pattern and/or an area of the at least one illumination feature may depend on the circle of confusion in the image.

- 5 The illumination features of the illumination pattern may be arranged such that only few reference features are positioned on an epipolar line. As shown in Figure 47A, the illumination pattern may comprise at least one hexagonal pattern, wherein the individual points are positioned on epipolar lines 2206. As shown in Figure 47B, the illumination pattern may comprise at least one hexagonal pattern, wherein the pattern is rotated relative to the baseline. Such a positioning
- 10 of the illumination features allows enhancing distance between the individual points on each epipolar line. For example as shown in Figure 47C, the illumination pattern may comprise at least one displaced hexagonal pattern, wherein individual points of the hexagonal pattern are displaced by a random distance from the regular position, for example orthogonal to the epipolar line of the point. The displacement of the individual points may be smaller than half of the
- 15 distance between two parallel epipolar lines, preferably smaller than one fourth of the distance between two parallel epipolar lines. The displacement of the individual points may be as such that two points are not displaced above each other. Such a positioning allows to enhance the number of possible features per area.
- 20 Figure 48 shows an embodiment of a scanning device 154. The scanning device may be adapted as a line scanning device. In particular, the scanning device 154 may comprise at least one sensor line or row of optical sensors 113. Furthermore, the scanning device may comprise the at least one transfer device 128 and the at least one illumination source 136. Triangulation systems require a sufficient baseline, however due to the baseline in the near field no detection
- 25 may be possible. Near field detection may be possible if the light spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. Thus, in triangulation systems, the non-zero baseline will always lead to a substantial reduction in the measurement range, in the near field, and/or in the far field. Reducing the baseline as possible with the detector according to the present invention will thus always increase the measurement range. Further, these near field and far field
- 30 problems can be overcome by using the scanning device 154 of Figure 48. The scanning device 154 may be adapted to detect a plurality of light beams 116 propagating from the object 112 to the scanning device 154 on the CMOS line. The light beams 116 may be generated at different position on the object 112 or by movement of the object 112. The scanning device 154 may be
- 35 adapted to determine at least one longitudinal coordinate for each of the light points by determining the quotient signal Q as described above.

Patent claims

1. A detector (110, 1110, 2110) for determining a position of at least one object (112, 1112), the detector (110, 1110, 2110) comprising:
 - 5 - at least one transfer device (128, 1128, 2128), wherein the transfer device (128, 1128, 2128) has at least one focal length in response to at least one incident light beam (116, 1116) propagating from the object (112, 1112, 2112) to the detector (110, 1110, 2110);
 - 10 - at least two optical sensors (113, 1118, 1120, 2113), wherein each optical sensor (113, 1118, 1120) has at least one light sensitive area (121, 1122, 1124, 2121), wherein each optical sensor (113, 1118, 1120, 2113) is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by the light beam (116, 1116, 2131),
 - 15 - at least one evaluation device (132, 1132, 2133) being configured for determining at least one longitudinal coordinate z of the object (112, 1112, 2112) by evaluating a quotient signal Q from the sensor signals;
 wherein the detector is adapted to determine the longitudinal coordinate z of the object in at least one measurement range independent from the object size in an object plane.
- 20 2. The detector (110, 1110, 2110) according to the preceding claim, wherein the measurement range is adjustable by adjusting one or more parameters selected from the group consisting of: a longitudinal distance from the object to the transfer device z_0 ; the focal length of the transfer device f ; a diameter of an exit pupil of the transfer device E_x ; a longitudinal distance from the transfer device to the light sensitive area z_s , a distance from the transfer device to
 25 an image of the object z_i ; an object size O_{size} of the object in the object plane.
3. The detector (110, 1110, 2110) according to the preceding claim, wherein the detector is adapted to determine the longitudinal coordinate z of the object independent from the object size if a circle of confusion of at least one light beam emitted from at least one point of the
 30 object is greater than an image size of the object.
4. The detector (110, 1110, 2110) according to the preceding claim, wherein the detector is adapted to determine the longitudinal coordinate z of the object independent from the object size if $O_{size} < \frac{z_0 E_x}{z_i^2} |z_s - z_i|$ holds true for at least one distance.
- 35 5. The detector (110, 1110, 2110) according to the preceding claim, wherein a lower object size limit is preferably 0.5 μm or more, more preferably 1 μm or more and most preferably 10 μm or more.
- 40 6. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the evaluation device (132) is configured for deriving the quotient signal Q by one or more of di-

viding the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.

7. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the evaluation device (132) is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate for determining the longitudinal coordinate.
8. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the evaluation device (132) is configured for deriving the quotient signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A1 and A2 are areas of the beam profile at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o.

9. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the optical sensors (113) are positioned off focus.
10. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the transfer device (128) has an optical axis (129), wherein the transfer device (128) constitutes a coordinate system, wherein a longitudinal coordinate l is a coordinate along the optical axis (129) and wherein d is a spatial offset from the optical axis (129), wherein the optical sensors (113) are arranged such that the light-sensitive areas (121) of the optical sensors (113) differ in at least one of: their longitudinal coordinate, their spatial offset, or their surface areas.
11. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein each of the sensor signals comprises at least one information of at least one area of the beam profile of at least one beam profile of the light beam.
12. The detector (110, 1110, 2110) according to the preceding claim, wherein the beam profile is selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles.
13. The detector (110, 1110, 2110) according to any one of the two preceding claims, wherein the light-sensitive regions are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a

second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.

14. The detector (110, 1110, 2110) according to the preceding claim, wherein the evaluation device (132) is configured to determine the first area of the beam profile and the second area of the beam profile.
15. The detector (110, 1110, 2110) according to any one of the four preceding claims, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile.
16. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the edge information comprises information relating to a number of photons in the first area of the beam profile and the center information comprises information relating to a number of photons in the second area of the beam profile.
17. The detector (110, 1110, 2110) according to any one of the two the preceding claims, wherein the evaluation device (132) is configured to derive the quotient signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information.
18. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the optical sensors (113) comprise a first optical sensor (118) having a first light sensitive area (122) and a second optical sensor (120) having a second light sensitive area (124), wherein the first and the second light sensitive areas (122, 124) are arranged such that a condition

$$\frac{a}{c} \neq \frac{b}{d}$$
 is satisfied, wherein a is a ratio of photons hitting both an inner region of a plane perpendicular to the optical axis (129) intersecting the optical axis (129) at a distance equal to half of a focal length of the transfer device (129) and the first light sensitive area (122), b is a ratio of photons hitting both the inner region of the plane and the second light sensitive area (124), c is a ratio of photons hitting both an outer region of the plane and the first light-sensitive area (122), d is a ratio of the photons hitting both the outer region of the plane and the second light sensitive area (124).
19. The detector (110, 1110, 2110) according to the preceding claim, wherein the first light sensitive area (118) and the second light sensitive area (122) are arranged such that the inner region has an area with a geometrical center point on the optical axis (129) and an ex-

tension such that half of the photons hit the plane within the inner region and the other half hit the plane outside the inner region.

20. The detector (110, 1110, 2110) according to the preceding claim, wherein the first light sensitive area (118) and the second light sensitive area (122) are arranged such that the inner region is designed as a circle with a center point on the optical axis and a radius r which is chosen such that half of the photons hit the plane within the circle and the other half hit the plane outside the circle.
21. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the optical sensors (113) comprise a first optical sensor (118) having a first light sensitive area (122) and a second optical sensor (120) having a second light sensitive area (124),
- wherein the first optical sensor (118) is configured to generate at least one first sensor signal in response to the illumination of the first light-sensitive area (122) by the light beam (116) propagating from the object (112) to the detector (110, 1110, 2110);
 - wherein the second optical sensor (120) is configured to generate at least one second sensor signal in response to the illumination of the second light-sensitive area (124) by the light beam (116), wherein the first light-sensitive area (122) is smaller than the second light-sensitive area (124).
22. The detector (110, 1110, 2110) according to the preceding claim, wherein the evaluation device (132) is configured for deriving the quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals, wherein the evaluation device (132) is configured for determining the longitudinal coordinate by evaluating the quotient signal Q .
23. The detector (110, 1110, 2110) according to any one of the two preceding claims, wherein the first and second optical sensors (118, 120) are arranged linearly in one and the same beam path of the detector (110, 1110, 2110).
24. The detector (110, 1110, 2110) according to the preceding claim, wherein the first and second optical sensors (118, 120) are arranged concentrically with respect to an optical axis (126) of the detector (110, 1110, 2110).
25. The detector (110, 1110, 2110) according to any one of the four preceding claims, wherein the first and second optical sensors (118, 120) each are semiconductor sensors, preferably inorganic semiconductor sensors, more preferably photodiodes and most preferably silicon photodiodes.

26. The detector (110, 1110, 2110) according to any one of the five preceding claims, wherein the first and second optical sensors (118, 120) each are uniform sensors having a single light-sensitive area each.
- 5 27. The detector (110, 1110, 2110) according to any one of the six preceding claims, wherein the detector (110, 1110, 2110) further comprises an illumination source (136) for illuminating the object (112).
- 10 28. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein the detector (110, 1110, 2110) has
- at least one sensor element (115) having a matrix (117) of optical sensors (113), the optical sensors (113) each having a light-sensitive area (121), wherein each optical sensor (113) is configured to generate at least one sensor signal in response to an illumination of the light-sensitive area (121) by at least one light beam (116) propagating from the object (112) to the detector (110, 1110, 2110);
 - 15 - the at least one evaluation device (132) configured for evaluating the sensor signals, by
 - a) determining at least one optical sensor (113) having the highest sensor signal and forming at least one center signal;
 - 20 b) evaluating the sensor signals of the optical sensors (113) of the matrix (117) and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and
 - 25 d) determining at least one longitudinal coordinate z of the object (112) by evaluating the combined signal.
29. The detector (110, 1110, 2110) according to the preceding claim, wherein the center signal is selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors (113) containing the optical sensor (113) having the highest sensor signal and a predetermined group of neighboring optical sensors (113); a sum of sensor signals from a group of optical sensors (113) containing the optical sensor (113) having the highest sensor signal and a predetermined group of neighboring optical sensors (113); a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors (113) containing the optical sensor (113) having the highest sensor signal and a predetermined group of neighboring optical sensors (113); an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.
- 30
- 35
- 40

30. The detector (110, 1110, 2110) according to any one of the two preceding claims, wherein the sum signal is selected from the group consisting of: an average over all sensor signals of the matrix (117); a sum of all sensor signals of the matrix (117); an integral of all sensor signals of the matrix (117); an average over all sensor signals of the matrix (117) except for sensor signals from those optical sensors (113) contributing to the center signal; a sum of all sensor signals of the matrix (117) except for sensor signals from those optical sensors (113) contributing to the center signal; an integral of all sensor signals of the matrix (117) except for sensor signals from those optical sensors (113) contributing to the center signal; a sum of sensor signals of optical sensors (113) within a predetermined range from the optical sensor (113) having the highest sensor signal; an integral of sensor signals of optical sensors (113) within a predetermined range from the optical sensor (113) having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors (113) being located within a predetermined range from the optical sensor (113) having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors (113) being located within a predetermined range from the optical sensor (113) having the highest sensor signal.
31. The detector (110, 1110, 2110) according to any one of the three preceding claims, wherein the combined signal is the quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal.
32. The detector (110, 1110, 2110) according to the preceding claim, wherein the evaluation device (132) is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate for determining the longitudinal coordinate.
33. The detector (110, 1110, 2110) according to any one of the two preceding claims, wherein the evaluation device (132) comprises at least one divider (142), wherein the divider (142) is configured for deriving the quotient signal.
34. The detector (110, 1110, 2110) according to any one of the six preceding claims, wherein the evaluation device (132) is further configured for determining at least one transversal coordinate of the object (112) by evaluating a transversal position of the at least one optical sensor (113) having the highest sensor signal.
35. The detector (110, 1110, 2110) according to any one of the preceding claims, wherein each light-sensitive area (122, 124) has a geometrical center (182, 184), wherein the geometrical centers (182, 184) of the optical sensors (118, 120, 176) are spaced apart from an optical

axis (126) of the detector (110, 1110, 2110) by different spatial offsets, wherein each optical sensor (118, 120, 176) is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area (122, 124) by a light beam (116) propagating from the object (112) to the detector (110, 1110, 2110).

5

36. The detector (110, 1110, 2110) according to the preceding claim, wherein the optical sensors (118, 120, 176) are part of a sensor array (174), wherein a geometrical center (180) of the sensor array (174) is offset from the optical axis (126).

10 37. The detector (110, 1110, 2110) according to the preceding claim, wherein the sensor array (174) is movable relative to the optical axis (126).

38. The detector (110, 1110, 2110) according to the preceding claim, wherein the evaluation device (132) is configured for, firstly, determining the transversal position of a light spot (186) generated by the light beam (116) on the sensor array (174) by using the sensor signals and for, secondly, moving the sensor array (174) relative to the optical axis (126) until the light spot (186) is off-centered.

15 39. The detector (110, 1110, 2110) according to any one of the four preceding claims, wherein the optical sensors (118, 120, 176) are partial diodes of a quadrant diode (178), with a geometrical center (180) of the quadrant diode (178) being off-centered from the optical axis (126) of the detector (110, 1110, 2110).

20 40. The detector (110, 1110, 2110) according to any one of the preceding claims, the detector (110, 1110, 2110) having

- at least one first optical sensor (1118) having a first light-sensitive area (1122), wherein the first optical sensor (1118) is configured to generate at least one first sensor signal in response to an illumination of the first light-sensitive area (122) by a light beam (1116) propagating from the object (1112) to the detector (1110);
- 30 - at least one second optical sensor (1120) having:
 - at least one fluorescent waveguiding sheet (1174) forming a second light-sensitive area (1124), wherein the fluorescent waveguiding sheet (1174) is oriented towards the object (1112) such that at least one light beam (1116) propagating from the object (1112) towards the detector (1110) generates at least one light spot (1202, 1204) in the second light-sensitive area (1124), wherein the fluorescent waveguiding sheet (1174) contains at least one fluorescent material (1180), wherein the fluorescent material (1180) is adapted to generate fluorescence light in response to the illumination by the light beam (1116); and
 - 35 ○ at least one photosensitive element (1182, 1184, 1186, 1188, 1212) located at at least one edge (1190, 1192, 1194, 1196) of the fluorescent waveguiding sheet (1174), capable of detecting fluorescence light guided from the light spot (1202, 1204) towards the photosensitive element (1182, 1184, 1186, 1188, 1212) by the fluorescent waveguiding sheet (1174) and capable of generating at least one second sensor signal in response to the illumination of the second light-sensitive
- 40

area (1124) by the light beam (1116), wherein the first light-sensitive area (1122) is smaller than the second light-sensitive area (1124); and

- at least one evaluation device (1132) being configured for determining at least one longitudinal coordinate z of the object (1112) by evaluating the first and second sensor signals.

5

41. The detector (110, 1110, 2110) according to the preceding claim, wherein the at least one photosensitive element (1182, 1184, 1186, 1188, 1212) is optically coupled to the fluorescent waveguiding sheet (1174) by at least one optical coupling element (1216) configured for at least partially coupling the fluorescence light guided by the fluorescent waveguiding sheet (1174) out of the fluorescent waveguiding sheet (1174).
42. The detector (110, 1110, 2110) according to any one of the two preceding claims, wherein the evaluation device (1132) is configured for deriving a quotient signal Q by dividing the first and second sensor signals, by dividing multiples of the first and second sensor signals or by dividing linear combinations of the first and second sensor signals, wherein the evaluation device (1132) is configured for determining the longitudinal coordinate by evaluating the quotient signal Q .
43. The detector (110, 1110, 2110) according to the preceding claim, wherein the evaluation device (1132) is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate.
44. The detector (110, 1110, 2110) according to any one of the four preceding claims, wherein the first optical sensor (1118) is located in front of the second optical sensor (1120), preferably such that the light beam (1116), in the given order, illuminates the first optical sensor (1118) and, afterwards, the second optical sensor (1120).
45. The detector (110, 1110, 2110) according to any one of the five preceding claims, wherein the second optical sensor (1120) comprises at least two photosensitive elements (1182, 1184, 1186, 1188, 1212) located at at least two edges (1190, 1192, 1194, 1196) of the fluorescent waveguiding sheet (1174), capable of detecting fluorescence light guided from the light spot (1202, 1204) towards the photosensitive elements (1182, 1184, 1186, 1188, 1212) by the fluorescent waveguiding sheet (1174) and capable of generating at least one sensor signal each.
46. The detector (110, 1110, 2110) according to the preceding claim, wherein the evaluation device (1132) comprises at least one summing device (1208) configured for summing up the sensor signals of the at least two photosensitive elements (1182, 1184, 1186, 1188, 1212), thereby forming a sum signal S , wherein the evaluation device (1132) is configured to determine the at least one longitudinal coordinate z of the object (1112) by using at least one predetermined relationship between the first sensor signal, the sum signal S of the second sensor signals and the longitudinal coordinate z .

10

15

20

25

30

35

40

47. The detector (110, 1110, 2110) according to any one of the two preceding claims, wherein the evaluation device (1132) is further configured to determine at least one transversal coordinate x, y of the object (1112) by evaluating the sensor signals of the photosensitive elements (1182, 1184, 1186, 1188, 1212).
- 5 48. The detector (110, 1110, 2110) according to any one of the eight preceding claims, wherein the second light-sensitive area (1124) is larger by at least a factor of two than the first light-sensitive area (1122).
- 10 49. The detector (110, 1110, 2110) according to any one of the nine preceding claims, wherein the detector (110, 1110, 2110) further comprises an illumination source (1136) for illuminating the object (1112).
- 15 50. The detector (110, 1110, 2110) according to any one of the preceding claims, the detector (2110) comprising:
- at least one angle dependent optical element (2130) adapted to generate at least one light beam (2131) having at least one beam profile depending on an angle of incidence of an incident light beam (2116) propagating from the object (2112) towards the detector (2110) and illuminating the angle dependent optical element (2130);
 - 20 - at least two optical sensors (2113), wherein each optical sensor (2113) has at least one light sensitive area (2121), wherein each optical sensor (2113) is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area by the light beam (2131) generated by the angle dependent optical element (130);
 - 25 - at least one evaluation device (2133) being configured for determining at least one longitudinal coordinate z of the object (2112) by evaluating the quotient signal Q from the sensor signals.
- 30 51. The detector (2110) according to the preceding claim, wherein the angle dependent optical element (2130) comprises at least one optical element selected from the group consisting of: at least one optical fiber, in particular at least one multifurcated optical fiber, in particular at least one bifurcated optical fiber; at least one diffractive optical element; at least one angle dependent reflective element, at least one diffractive grating element, in particular a blaze grating element; at least one aperture stop; at least one prism; at least one lens; at least one lens array, in particular at least one microlens array; at least one optical filter; at least one polarization filter; at least one bandpass filter; at least one liquid crystal filter, in particular a liquid crystal tunable filter; at least one short-pass filter; at least one long-pass filter; at least one notch filter; at least one interference filter; at least one transmission grating; at least one nonlinear optical element, in particular one birefringent optical element.
- 35 52. A detector system (134) for determining a position of at least one object (112), the detector system (134) comprising at least one detector (110, 1110, 2110) according to any one of the preceding claims, the detector system (134) further comprising at least one beacon device (114) adapted to direct at least one light beam (116) towards the detector (110, 1110, 2110),
- 40

wherein the beacon device (114) is at least one of attachable to the object (112), holdable by the object (112) and integratable into the object (112).

53. A human-machine interface (148) for exchanging at least one item of information between a user (162) and a machine (170), wherein the human-machine interface (148) comprises at least one detector system (134) according to the preceding claim, wherein the at least one beacon device (114) is adapted to be at least one of directly or indirectly attached to the user (162) and held by the user (162), wherein the human-machine interface (148) is designed to determine at least one position of the user (162) by means of the detector system (134), wherein the human-machine interface (148) is designed to assign to the position at least one item of information.
54. An entertainment device (150) for carrying out at least one entertainment function, wherein the entertainment device (150) comprises at least one human-machine interface (148) according to the preceding claim, wherein the entertainment device (150) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (148), wherein the entertainment device (150) is designed to vary the entertainment function in accordance with the information.
55. A tracking system (152) for tracking a position of at least one movable object (112), the tracking system (152) comprising at least one detector system (134) according to any one of the preceding claims referring to a detector system (134), the tracking system (152) further comprising at least one track controller (172), wherein the track controller (172) is adapted to track a series of positions of the object (112) at specific points in time.
56. A scanning system (154) for determining a depth profile of a scenery, the scanning system (154) comprising at least one detector (110, 1110, 2110) according to any of the preceding claims referring to a detector (110, 1110, 2110), the scanning system (154) further comprising at least one illumination source (136) adapted to scan the scenery with at least one light beam (116).
57. A camera (146) for imaging at least one object (112), the camera (146) comprising at least one detector (110, 1110, 2110) according to any one of the preceding claims referring to a detector (110, 1110, 2110).
58. A readout device (192) for optical storage media, the readout device (192) comprising at least one detector (110, 1110, 2110) according to any one of the preceding claims referring to a detector (110, 1110, 2110).
59. A method for determining a position of at least one object (112) by using at least one detector (110, 1110, 2110), the method comprising the following steps:
- providing at least two optical sensors (113), each optical sensor (113) having a light-sensitive area (121), wherein each optical sensor (113) is configured to generate a sen-

- sor signal in response to an illumination of its respective light-sensitive area by a light beam (116), wherein the detector has at least one transfer device (128), wherein the transfer device (128) has at least one focal length in response to the light beam (116) propagating from the object (112) to the detector (110, 1110, 2110);
- 5 - illuminating each of the light-sensitive areas (121) of the at least two optical sensors (113) of the detector with the light beam (116) propagating from the object (112) to the detector (110, 1110, 2110), wherein, thereby, each of the light-sensitive areas (121) generates at least one sensor signal; and
- 10 - evaluating the sensor signals, thereby, determining at least one longitudinal coordinate z of the object (112), wherein the evaluating comprises deriving a quotient signal Q of the sensor signals,
wherein the longitudinal coordinate z of the object is determined in at least one measurement range independent from the object size in an object plane.
- 15 60. The method according to the preceding claim, wherein the deriving of the quotient signal Q comprises one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals.
- 20 61. The method according to any one of the preceding claims referring to a method, wherein the method comprises adjusting the measurement range by adjusting on one or more parameters selected from the group consisting of: a longitudinal distance from the object to the transfer device z_0 ; the focal length of the transfer device f ; a diameter of an exit pupil of the transfer device E_x ; a longitudinal distance from the transfer device to the light sensitive area z_s , a distance from the transfer device to an image of the object z_i ; an object size O_{size} of the object in the object plane.
- 25 62. The method according to any one of the preceding claims referring to a method, wherein the transfer device (128) has an optical axis (129), wherein the transfer device (128) constitutes a coordinate system, wherein a longitudinal coordinate l is a coordinate along the optical axis (129) and wherein d is a spatial offset from the optical axis (129), wherein the method comprises arranging the optical sensors (113) such that the light-sensitive areas (121) of the optical sensors (113) differ in at least one of: their longitudinal coordinate, their spatial offset, or their surface areas.
- 30 63. The method according to any one of the preceding claims referring to a method, wherein each of the sensor signals comprises at least one information of at least one beam profile of the light beam, wherein the beam profile is selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles, wherein the light-sensitive regions are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.
- 35 40

64. The method according to the preceding claim, wherein the evaluating comprises determining the first area of the beam profile and the second area of the beam profile.
- 5 65. The method according to any one of the two preceding claims, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile, wherein the edge information comprises an information relating to a number of photons in the first area of the beam profile and the center information comprises an information relating to a number of photons in the second area of the beam profile, wherein the evaluating comprises deriving the quotient signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information.
- 10
- 15 66. The method according to any one of the preceding claims referring to a method, the method comprising the following steps:
- illuminating at least one first light-sensitive area (122) of at least one first optical sensor (118) of the detector (110, 1110, 2110) with the light beam (116) propagating from the object (112) to the detector (110, 1110, 2110) and, thereby, generating at least one first sensor signal;
 - illuminating at least one second light-sensitive area (124) of at least one second optical sensor (120) of the detector (110, 1110, 2110) with the light beam (116) and, thereby, generating at least one second sensor signal, wherein the first light-sensitive area (122) is smaller than the second light-sensitive area (124).
- 20
- 25
67. The method according to any one of the preceding claims referring to a method, the method comprising the following steps:
- illuminating at least one sensor element (115) of the detector (110, 1110, 2110) with the at least one light beam (116) propagating from the object (112) to the detector (110, 1110, 2110), the detector (110, 1110, 2110) having a matrix (117) of optical sensors (113), the optical sensors (113) each having a light-sensitive area (121), wherein each optical sensor (113) generates at least one sensor signal in response to the illumination;
 - evaluating the sensor signals, by
 - a) determining at least one optical sensor (113) having the highest sensor signal and forming at least one center signal;
 - b) evaluating the sensor signals of the optical sensors (113) of the matrix (117) and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and
 - d) determining at least one longitudinal coordinate z of the object (112) by evaluating the combined signal.
- 30
- 35
- 40

68. The method according to the preceding claim, wherein the combined signal is the quotient signal Q, derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal.
69. The method according to any one of the preceding claims referring to a method, wherein each light-sensitive area (122, 124) has a geometrical center (182, 184), wherein the geometrical centers (182, 184) of the optical sensors (118, 120, 176) are spaced apart from an optical axis (126) of the detector (110, 1110, 2110) by different separations.
70. The method according to any one of the preceding claims referring to a method, the method comprising the following steps:
- illuminating at least one first light-sensitive area (1122) of at least one first optical sensor (1118) with a light beam (1116) propagating from the object (1112) to the detector (110, 1110, 2110) and generating at least one first sensor signal by the first optical sensor (1118), in response to the illumination of the first light-sensitive area (1122);
 - illuminating at least one second light-sensitive area (1124) of at least one second optical sensor (1120) with the light beam (1116) and generating at least one second sensor signal by the second optical sensor (1120), in response to the illumination of the second light-sensitive area (1124), the second optical sensor (1120) having:
 - o at least one fluorescent waveguiding sheet (1174) forming a second light-sensitive area (1124), wherein the fluorescent waveguiding sheet (1174) is oriented towards the object (1112) such that at least one light beam (1116) propagating from the object (1112) towards the detector (110, 1110, 2110) generates at least one light spot (1202, 1204) in the second light-sensitive area (1124), wherein the fluorescent waveguiding sheet (1174) contains at least one fluorescent material (1180), wherein the fluorescent material (1180) is adapted to generate fluorescence light in response to the illumination by the light beam (1116); and
 - o at least one photosensitive element (1182, 1184, 1186, 1188, 1212) located at at least one edge (1190, 1192, 1194, 1196) of the fluorescent waveguiding sheet (1174), capable of detecting fluorescence light guided from the light spot (1202, 1204) towards the photosensitive element (1182, 1184, 1186, 1188, 1212) by the fluorescent waveguiding sheet (1174) and capable of generating the at least one second sensor signal in response to the illumination of the second light-sensitive area (1124) by the light beam (1116), wherein the first light-sensitive area (1122) is smaller than the second light-sensitive area (1124); and
 - determining at least one longitudinal coordinate z of the object (1112) by evaluating the first and second sensor signals.

71. The method according to any one of the preceding claims referring to a method, the method comprising the following steps:
- providing at least one angle dependent optical element (130) and generating at least one light beam (131) having at least one beam profile depending on an angle of incidence;
 - providing at least two optical sensors (113), wherein each optical sensor (113) has at least one light sensitive area (121), wherein each optical sensor (113) is designed to generate at least one sensor signal in response to an illumination of its respective light-sensitive area (121) by the light beam (131) generated by the angle dependent optical element (130);
 - illuminating each of the light-sensitive areas (131) of the at least two optical sensors (113) of the detector (110) with the light beam (131) generated by the angle dependent optical element (130), wherein, thereby, each of the light-sensitive areas (121) generates at least one sensor signal; and
 - evaluating the sensor signals, thereby, determining at least one longitudinal coordinate z of the object (112), wherein the evaluating comprises deriving the quotient signal Q of the sensor signals.
72. A use of the detector (110, 1110, 2110) according to any one of the preceding claims relating to a detector (110, 1110, 2110), for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; an optical data storage application; a security application; a surveillance application; a safety application; a human-machine interface (148) application; a logistics application; a tracking application; a photography application; a machine vision application; a robotics application; a quality control application; a manufacturing application; a use in combination with optical data storage and readout.

(54) Title: DETECTOR FOR OPTICALLY DETECTING AT LEAST ONE OBJECT

FIG.3

(57) **Abstract:** A detector (110) for determining a position of at least one object (112) is disclosed. The detector (110) comprises: - at least one sensor element (118) having a matrix (120) of optical sensors (122), the optical sensors (122) each having a light-sensitive area (124), wherein each optical sensor (122) is configured to generate at least one sensor signal in response to an illumination of the light-sensitive area (124) by at least one light beam (116) propagating from the object (112) to the detector (110); - at least one evaluation device (134) configured for evaluating the sensor signals, by a) determining at least one optical sensor (122) having the highest sensor signal and forming at least one center signal; b) evaluating the sensor signals of the optical sensors (122) of the matrix (120) and forming at least one sum signal; c) determining at least one combined signal by combining the center signal and the sum signal; and d) determining at least one longitudinal coordinate z of the object (112) by evaluating the combined signal.

Detector for optically detecting at least one object

Description

5 Field of the invention

The invention relates to a detector, a detector system and a method for determining a position of at least one object. The invention further relates to a human-machine interface for exchanging at least one item of information between a user and a machine, an entertainment device, a tracking system, a camera, a scanning system and various uses of the detector device. The
10 devices, systems, methods and uses according to the present invention specifically may be employed for example in various areas of daily life, gaming, traffic technology, production technology, security technology, photography such as digital photography or video photography for arts, documentation or technical purposes, medical technology or in the sciences. Further, the
15 invention specifically may be used for scanning one or more objects and/or for scanning a scenery, such as for generating a depth profile of an object or of a scenery, e.g. in the field of architecture, metrology, archaeology, arts, medicine, engineering or manufacturing. However, other applications are also possible.

20 Prior art

A large number of optical sensors and photovoltaic devices are known from the prior art. While photovoltaic devices are generally used to convert electromagnetic radiation, for example, ultra-violet, visible or infrared light, into electrical signals or electrical energy, optical detectors are
25 generally used for picking up image information and/or for detecting at least one optical parameter, for example, a brightness.

A large number of optical sensors which can be based generally on the use of inorganic and/or organic sensor materials are known from the prior art. Examples of such sensors are disclosed
30 in US 2007/0176165 A1, US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1 or else in numerous other prior art documents. To an increasing extent, in particular for cost reasons and for reasons of large-area processing, sensors comprising at least one organic sensor material are being used, as described for example in US 2007/0176165 A1. In particular, so-called dye solar cells are increasingly of importance here, which are described generally, for example in WO
35 2009/013282 A1.

A large number of detectors for detecting at least one object are known on the basis of such optical sensors. Such detectors can be embodied in diverse ways, depending on the respective purpose of use. Examples of such detectors are imaging devices, for example, cameras and/or
40 microscopes. High-resolution confocal microscopes are known, for example, which can be used in particular in the field of medical technology and biology in order to examine biological samples with high optical resolution. Further examples of detectors for optically detecting at least one object are distance measuring devices based, for example, on propagation time methods of corresponding optical signals, for example laser pulses. Further examples of detectors for opti-

cally detecting objects are triangulation systems, by means of which distance measurements can likewise be carried out. Kurt Konolige et al., A Low-Cost Laser Distance Sensor, 2008 IEEE International Conference on Robotics and Automation, Pasadena, CA, USA, May 19-23, 2008, discuss competing technologies using triangulation for planar laser distance sensor (LDS).

5 Structured line devices use a light stripe laser and offset camera to determine range to a set of points. Because the laser energy is spread over a line, it is difficult to achieve accurate range, especially in the presence of ambient light, or with darker objects. Point scan devices for 3D scanning of small objects typically use a scanning mirror to direct a point laser beam and redirect the laser return to an optical receiver. Such devices cannot be miniaturized, and their cost and mechanical fragility will remain high. Centroid point modules typically use position-sensitive devices (PSD). These devices measure the centroid of all light impinging on their surface. Although modulation techniques can be used to offset some of the effects of ambient light, PSDs do not perform well unless the laser spot has a very strong reflection, limiting their use to ranges of a meter or less. Pixel-based point modules search the pixel with maximum signal intensity to determine the position of the light spot on the sensor. Typically CMOS line arrays are used for detection. Konolige et al. introduce a low-cost version of a Pixel-based point module.

US 5 235 377 A describes a measuring apparatus for a camera, wherein light is projected to an object from a projection section. Light reflected on the object is received at a first light receiving section and a second light receiving section arranged to be adjacent to each other. In the first light receiving section, a first and second signals relating to a light receiving position and a quantity of received light are output, and in the second light receiving section, a third signal relating to a quantity of light of the reflected light is output. In a discriminating and calculating section, if it is discriminated that the reflected light is positioned at a place, which is nearer than a predetermined distance, a measuring distance can be calculated from an output ratio of the first signal to the second signal by a measuring calculation circuit. On the other hand, if it is discriminated that the reflected light is positioned at a place, which is farther than the predetermined distance, a measuring distance can be calculated from the output ratio of the sum of the first and second signals to the third signal by the measuring calculation circuit.

US 5 512 997 A describes a distance measuring device having an infrared light-emitting diode by which an infrared light is emitted towards a subject, and first and second linear line sensors on which an image corresponding to light reflected from the subject is formed. The first and second linear line sensors are disposed adjacently and in parallel to each other, and offset by an amount corresponding to half of the predetermined A/D converting step. Analog distance data outputted from the linear line sensors are converted to digital distance data using the predetermined A/D converting step, and then, the digital distance data are added together to obtain a subject distance with a high accuracy.

DE 42 11 875 A1 describes an optical rangefinder with electronic correction for spot eccentricity. The optical rangefinder has an evaluation circuit, which determines if an output distance measurement value is valid or erroneous due to e.g. inclination of object surface. The distance signal is determined by evaluation a position a light spot on a first detector. A second control

signal, which characterizes inclination of the object surface, is determined by evaluating eccentricity of a light spot on a second detector, arranged in a different plane.

5 WO 2016/051323 A1 describes a detector and a method for optically determining a position of at least one object. The detector comprises at least one optical sensor for determining a position of at least one light beam and at least one evaluation device for generating at least one item of information on a transversal position of the object and at least one item of information on a longitudinal position of the object. The sensor has at least a first electrode and a second electrode. At least one photovoltaic material is embedded in between the first electrode and the
10 second electrode. The first electrode or the second electrode is a split electrode having at least three partial electrodes. The detector and the method can determine three-dimensional coordinates of an object in a fast and efficient way.

15 In WO 2012/110924 A1, the content of which is herewith included by reference, a detector for optically detecting at least one object is proposed. The detector comprises at least one optical sensor. The optical sensor has at least one sensor region. The optical sensor is designed to generate at least one sensor signal in a manner dependent on an illumination of the sensor region. The sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor
20 area. The detector furthermore has at least one evaluation device. The evaluation device is designed to generate at least one item of geometrical information from the sensor signal, in particular at least one item of geometrical information about the illumination and/or the object.

25 WO 2014/097181 A1, the full content of which is herewith included by reference, discloses a method and a detector for determining a position of at least one object, by using at least one transversal optical sensor and at least one optical sensor. Specifically, the use of sensor stacks is disclosed, in order to determine a longitudinal position of the object with a high degree of accuracy and without ambiguity.

30 WO 2015/024871 A1 and US 2015/286340 A1, the full content of which is herewith included by reference, discloses an optical detector, comprising:

- at least one spatial light modulator being adapted to modify at least one property of a light beam in a spatially resolved fashion, having a matrix of pixels, each pixel being controllable to individually modify the at least one optical property of a portion of the light beam passing the
35 pixel;
- at least one optical sensor adapted to detect the light beam after passing the matrix of pixels of the spatial light modulator and to generate at least one sensor signal;
- at least one modulator device adapted for periodically controlling at least two of the pixels with different modulation frequencies; and
- 40 – at least one evaluation device adapted for performing a frequency analysis in order to determine signal components of the sensor signal for the modulation frequencies.

US 4,767,211 discloses an apparatus for and a method of measuring a boundary surface of a sample in which a ratio of the light quantity of a part of reflected light from a sample which travels in the vicinity of the optical axis of the reflected light, to the light quantity of another part of the reflected light which is directed to a position deviating from the optical axis by a predetermined distance is used to accurately measure a boundary surface of a sample. Since the accuracy of measurement is increased by using the above ratio, light capable of passing through the sample can be used as incident light. Thus, a deep hole in the surface of the sample and a void such as an air bubble in a living being sample, which cannot be measured by the prior art, can be measured very accurately.

WO 2014/198629 A1, the full content of which is herewith included by reference, discloses a detector for determining a position of at least one object, comprising:

- at least one optical sensor, the optical sensor being adapted to detect a light beam propagating from the object towards the detector, the optical sensor having at least one matrix of pixels; and
- at least one evaluation device, the evaluation device being adapted to determine a number N of pixels of the optical sensor which are illuminated by the light beam, the evaluation device further being adapted to determine at least one longitudinal coordinate of the object by using the number N of pixels which are illuminated by the light beam.

Further, generally, for various other detector concepts, reference may be made to WO 2014/198626 A1, WO 2014/198629 A1 and WO 2014/198625 A1, the full content of which is herewith included by reference. Further, referring to potential materials and optical sensors which may also be employed in the context of the present invention, reference may be made to European patent applications EP 15 153 215.7, filed on January 30, 2015, EP 15 157 363.1, filed on March 3, 2015, EP 15 164 653.6, filed on April 22, 2015, EP 15177275.3, filed on July 17, 2015, EP 15180354.1 and EP 15180353.3, both filed on August 10, 2015, and EP 15 185 005.4, filed on September 14, 2015, EP 15 196 238.8 and EP 15 196 239.6, both filed on November 25, 2015, EP 15 197 744.4, filed on December 3, 2015, the full content of all of which is herewith also included by reference.

US 2006/044546 A1 describes a ranging apparatus capable of ranging simultaneously to a three dimensional scene. An illumination means illuminates a scene with a two dimensional array of spots. A detector is located near to the illumination means and arranged to look toward the scene. A processor responds to the output from the detector and, from the location of a spot in the image of the scene, determines the range to that spot.

US 2008/13005 A1 describes driving schemes in which rows are selected one at a time and column data voltages are inverted to provide inversion schemes for display devices comprising pixels arranged in rows and columns. The order in which rows are selected is such that a first group of first polarity rows is selected in a first order, a first group of second polarity rows is selected in a second order, a second group of first polarity rows is selected in the second order,

and a second group of second polarity rows is selected in the first order, the first order being one of ascending or descending row number order, and the second order being the other of ascending or descending row number order.

- 5 Despite the advantages implied by the above-mentioned devices and detectors, several technical challenges remain. Thus, generally, a need exists for detectors for detecting a position of an object in space which is both reliable and may be manufactured at low cost. Specifically, a need exists for 3D-sensing concepts. Various known concepts are at least partially based on using so-called FiP sensors, such as several of the above-mentioned concepts. Therein, as an
- 10 example, large area sensors may be used, in which the individual sensor pixels are significantly larger than the light spot and which are fixed to a specific size. Still, large area sensors in many cases are inherently limited in the use of the FiP measurement principle, specifically in case more than one light spot is to be investigated simultaneously.
- 15 A further challenge using FiP detectors is the detector area or active area. Typically, for distance measurements, a large active area of the detector is used or even is required. This area, however, may cause noise problems, specifically when the tetralateral conductivity concept is employed to build a PSD. This often results in poor signal-to-noise-ratios and slow detector response times due to the large capacitance in conjunction with the series resistance of the detector. A further challenge using FiP detectors is cost of manufacturing. Thus, in many cases, typical FiP sensors are expensive, as compared to e.g. conventional Si-based photodiodes. Further, the evaluation of the measurement results of measurements using FiP-sensors remains an
- 20 issue, specifically in case the total power of a light beam is unknown. In case a plurality of FiP-sensors is used, located at different positions along an axis of propagation of the light beam, a range of measurement typically is limited to the range in between the two positions of the sensors. Further, many FiP-detectors show a luminance dependency which renders the evaluation of the measurement result more difficult, and, additionally, FiP-measurements in many cases are dependent on a target spot size.

30 Problem addressed by the invention

It is therefore an object of the present invention to provide devices and methods facing the above-mentioned technical challenges of known devices and methods. Specifically, it is an object of the present invention to provide devices and methods which reliably may determine a

35 position of an object in space, preferably with a low technical effort and with low requirements in terms of technical resources and cost.

Summary of the invention

- 40 This problem is solved by the invention with the features of the independent patent claims. Advantageous developments of the invention, which can be realized individually or in combination, are presented in the dependent claims and/or in the following specification and detailed embodiments.

As used in the following, the terms “have”, “comprise” or “include” or any arbitrary grammatical variations thereof are used in a non-exclusive way. Thus, these terms may both refer to a situation in which, besides the feature introduced by these terms, no further features are present in the entity described in this context and to a situation in which one or more further features are present. As an example, the expressions “A has B”, “A comprises B” and “A includes B” may both refer to a situation in which, besides B, no other element is present in A (i.e. a situation in which A solely and exclusively consists of B) and to a situation in which, besides B, one or more further elements are present in entity A, such as element C, elements C and D or even further elements.

Further, it shall be noted that the terms “at least one”, “one or more” or similar expressions indicating that a feature or element may be present once or more than once typically will be used only once when introducing the respective feature or element. In the following, in most cases, when referring to the respective feature or element, the expressions “at least one” or “one or more” will not be repeated, non-withstanding the fact that the respective feature or element may be present once or more than once.

Further, as used in the following, the terms “preferably”, “more preferably”, “particularly”, “more particularly”, “specifically”, “more specifically” or similar terms are used in conjunction with optional features, without restricting alternative possibilities. Thus, features introduced by these terms are optional features and are not intended to restrict the scope of the claims in any way. The invention may, as the skilled person will recognize, be performed by using alternative features. Similarly, features introduced by “in an embodiment of the invention” or similar expressions are intended to be optional features, without any restriction regarding alternative embodiments of the invention, without any restrictions regarding the scope of the invention and without any restriction regarding the possibility of combining the features introduced in such a way with other optional or non-optional features of the invention.

In a first aspect of the present invention, a detector for determining a position of at least one object is disclosed. As used herein, the term “position” refers to at least one item of information regarding a location and/or orientation of the object and/or at least one part of the object in space. Thus, the at least one item of information may imply at least one distance between at least one point of the object and the at least one detector. As will be outlined in further detail below, the distance may be a longitudinal coordinate or may contribute to determining a longitudinal coordinate of the point of the object. Additionally or alternatively, one or more other items of information regarding the location and/or orientation of the object and/or at least one part of the object may be determined. As an example, additionally, at least one transversal coordinate of the object and/or at least one part of the object may be determined. Thus, the position of the object may imply at least one longitudinal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one transversal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one orientation information of the object, indicating an orientation of the object in space.

The detector comprises:

- at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor is configured to generate at least one sensor signal in response to an illumination of the light-sensitive area by at least one light beam propagating from the object to the detector;
- at least one evaluation device configured for evaluating the sensor signals, by
 - a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
 - b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and
 - d) determining at least one longitudinal coordinate z of the object by evaluating the combined signal.

As used herein, the term “sensor element” generally refers to a device or a combination of a plurality of devices configured for sensing at least one parameter. In the present case, the parameter specifically may be an optical parameter, and the sensor element specifically may be an optical sensor element. The sensor element may be formed as a unitary, single device or as a combination of several devices.

As further used herein, the term “matrix” generally refers to an arrangement of a plurality of elements in a predetermined geometrical order. The matrix, as will be outlined in further detail below, specifically may be or may comprise a rectangular matrix having one or more rows and one or more columns. The rows and columns specifically may be arranged in a rectangular fashion. It shall be outlined, however, that other arrangements are feasible, such as nonrectangular arrangements. As an example, circular arrangements are also feasible, wherein the elements are arranged in concentric circles or ellipses about a center point. For example, the matrix may be a single row of pixels. Other arrangements are feasible.

As further used herein, an “optical sensor” generally refers to a light-sensitive device for detecting a light beam, such as for detecting an illumination and/or a light spot generated by at least one light beam. As further used herein, a “light-sensitive area” generally refers to an area of the optical sensor which may be illuminated externally, by the at least one light beam, in response to which illumination the at least one sensor signal is generated. The light-sensitive area may specifically be located on a surface of the respective optical sensor. Other embodiments, however, are feasible. The optical sensors of the matrix specifically may be equal in one or more of size, sensitivity and other optical, electrical and mechanical properties. The light-sensitive areas of all optical sensors of the matrix specifically may be located in a common plane, the common plane preferably facing the object, such that a light beam propagating from the object to the detector may generate a light spot on the common plane. As will further be outlined in detail below, each optical sensor, preferably, may be embodied such that precisely one light-sensitive area is present in the respective optical sensor, such as by providing precisely one light-

sensitive area which may be illuminated, in response to which illumination precisely one uniform sensor signal is created for the whole optical sensor. Thus, preferably, each optical sensor is a single area optical sensor rather than a pixelated optical sensor like e.g. a sensor matrix. Other embodiments, however, are feasible. The use of the single area optical sensors, however, renders the setup of the detector specifically simple and efficient. Thus, as an example, commercially available photosensors, such as commercially available silicon photodiodes, each having precisely one sensitive area, may be used in the setup, one with a small light-sensitive area and one with a larger light-sensitive area, as will be explained in further detail below.

As further used herein, a “sensor signal” generally refers to a signal generated by an optical sensor in response to the illumination by the light beam. Specifically, the sensor signal may be or may comprise at least one electrical signal, such as at least one analogue electrical signal and/or at least one digital electrical signal. More specifically, the sensor signal may be or may comprise at least one voltage signal and/or at least one current signal. More specifically, the sensor signal may comprise at least one photocurrent. Further, either raw sensor signals may be used, or the detector, the optical sensor or any other element may be adapted to process or preprocess the sensor signal, thereby generating secondary sensor signals, which may also be used as sensor signals, such as preprocessing by filtering or the like. The sensor signal may comprise at least one information of at least one beam profile of the light beam. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles.

The light-sensitive areas specifically may be oriented towards the object. As used herein, the term “is oriented towards the object” generally refers to the situation that the respective surfaces of the light-sensitive areas are fully or partially visible from the object. Specifically, at least one interconnecting line between at least one point of the object and at least one point of the respective light-sensitive area may form an angle with a surface element of the light-sensitive area which is different from 0° , such as an angle in the range of 20° to 90° , preferably 80° to 90° such as 90° . Thus, when the object is located on the optical axis or close to the optical axis, the light beam propagating from the object towards the detector may be essentially parallel to the optical axis. As used herein, the term “essentially perpendicular” refers to the condition of a perpendicular orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less. Similarly, the term “essentially parallel” refers to the condition of a parallel orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less.

The present invention may implement a general idea for determining the at least one longitudinal coordinate of the object, which might be characterized as follows. Thus, as explained in more detail in one or more of the above-mentioned prior art documents, e.g. in WO 2012/110924 A1 or WO 2014/097181 A1, typically, a predetermined or determinable relationship exists between a size of a light spot, such as a diameter of the light spot, a beam waist or an equivalent diameter, and the longitudinal coordinate of the object from which the light beam propagates towards the detector. Without wishing to be bound by this theory, the light spot, may

be characterized by two measurement variables: a measurement signal measured in a small measurement patch in the center or close to the center of the light spot, also referred to as the center signal, and an integral or sum signal integrated over the light spot, with or without the center signal. For a light beam having a certain total power which does not change when the beam is widened or focused, the sum signal should be independent from the spot size of the light spot, and, thus, should, at least when linear optical sensors within their respective measurement range are used, be independent from the distance between the object and the detector. The center signal, however, is dependent on the spot size. Thus, the center signal typically increases when the light beam is focused, and decreases when the light beam is defocused. By comparing the center signal and the sum signal, thus, an item of information on the size of the light spot generated by the light beam and, thus, on the longitudinal coordinate of the object may be generated. The comparing of the center signal and the sum signal, as an example, may be done by forming a combined signal Q out of the center signal and the sum signal and by using a predetermined or determinable relationship between the longitudinal coordinate and the combined signal for deriving the longitudinal coordinate.

The use of a matrix of optical sensors provides a plurality of advantages and benefits. Thus, the center of the light spot generated by the light beam on the sensor element, such as on the common plane of the light-sensitive areas of the optical sensors of the matrix of the sensor element, may vary with a transversal position of the object. By using a matrix of optical sensors, the detector according to the present invention may adapt to these changes in conditions and, thus, may determine the center of the light spot simply by comparing the sensor signals. Consequently, the detector according to the present invention may, by itself, choose the center signal and determine the sum signal and, from these two signals, derive a combined signal which contains information on the longitudinal coordinate of the object. By evaluating the combined signal, the longitudinal coordinate of the object may, thus, be determined. The use of the matrix of optical sensors, thus, provides a significant flexibility in terms of the position of the object, specifically in terms of a transversal position of the object.

The transversal position of the light spot on the matrix of optical sensors, such as the transversal position of the at least one optical sensor generating the sensor signal, may even be used as an additional item of information, from which at least one item of information on a transversal position of the object may be derived, as e.g. disclosed in WO 2014/198629 A1. Additionally or alternatively, as will be outlined in further detail below, the detector according to the present invention may contain at least one additional transversal detector for, in addition to the at least one longitudinal coordinate, detecting at least one transversal coordinate of the object.

Consequently, in accordance with the present invention, the term "center signal" generally refers to the at least one sensor signal of the at least one optical sensor having the highest sensor signal out of the plurality of sensor signals generated by the optical sensors of the entire matrix or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable within an image generated by the optical sensors of the matrix. As used herein, the term "highest sensor signal" refers to one or both of a local maximum or a maximum in a

region of interest. The center signal may arise from a single optical sensor or, as will be outlined in further detail below, from a group of optical sensors, wherein, in the latter case, as an example, the sensor signals of the group of optical sensors may be added up, integrated or averaged, in order to determine the center signal. The group of optical sensors from which the center signal arises may be a group of neighboring optical sensors, such as optical sensors having less than a predetermined distance from the actual optical sensor having the highest sensor signal, or may be a group of optical sensors generating sensor signals being within a predetermined range from the highest sensor signal. The group of optical sensors from which the center signal arises may be chosen as large as possible in order to allow maximum dynamic range.

The evaluation device may be adapted to determine the center signal by integration of the plurality of sensor signals, for example the plurality of optical sensors around the optical sensor having the highest sensor signal. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid, in particular of a plateau of the trapezoid.

Similarly, the term "sum signal" generally refers to a signal derived by adding up the sensor signals, integrating over the sensor signals or averaging over the sensor signals of the entire matrix or of a region of interest within the matrix, wherein the region of interest may be predetermined or determinable within an image generated by the optical sensors of the matrix. When adding up, integrating over or averaging over the sensor signals, the actual optical sensors from which the sensor signal is generated may be left out of the adding, integration or averaging or, alternatively, may be included into the adding, integration or averaging. The evaluation device may be adapted to determine the sum signal by integrating of signals of the entire matrix, of the region of interest within the matrix. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the entire trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of sum and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

Additionally or alternatively, the evaluation device may be adapted to determine one or both of the center signal or sum signal from at least one slice or cut of the light spot. Slices or cuts may be realized for example by using one or more specific rows and/or columns. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or cuts may result in an improved distance information.

Similarly, the term "combined signal", as used herein, generally refers to a signal which is generated by combining the center signal and the sum signal. Specifically, the combination may include one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa. Additionally or alternatively, the combined signal may comprise an

arbitrary signal or signal combination which contains at least one item of information on a comparison between the center signal and the sum signal.

5 The light beam propagating from the object to the detector specifically may fully illuminate the at least one optical sensor from which the center signal is generated, such that the at least one optical sensor from which the center signal arises is fully located within the light beam, with a width of the light beam being larger than the light-sensitive area of the at least one optical sensor from which the sensor signal arises. Contrarily, preferably, the light beam propagating from the object to the detector specifically may create a light spot on the entire matrix which is small-
10 er than the matrix, such that the light spot is fully located within the matrix. This situation may easily be adjusted by a person skilled in the art of optics by choosing one or more appropriate lenses or elements having a focusing or defocusing effect on the light beam, such as by using an appropriate transfer device as will be outlined in further detail below. As further used herein, a "light spot" generally refers to a visible or detectable round or non-round illumination of an
15 article, an area or object by a light beam.

The light beam may propagate from the object towards the detector. As will be outlined in further detail below, the light beam may originate from the object, such as by the object and/or at least one illumination source integrated or attached to the object emitting the light beam, or may
20 originate from a different illumination source, such as from an illumination source directly or indirectly illuminating the object, wherein the light beam is reflected or scattered by the object and, thereby, is at least partially directed towards the detector. The illumination source, as an example, may be or may comprise one or more of an external illumination source, and illumination source integrated into the detector or an illumination source integrated into a beacon device
25 being one or more of attached to the object, integrated into the object or held by the object.

As used herein, the term "ray" generally refers to a line that is perpendicular to wavefronts of light which points in a direction of energy flow. As used herein, the term "beam" generally refers to a collection of rays. In the following, the terms "ray" and "beam" will be used as synonyms. As
30 further used herein, the term "light beam" generally refers to an amount of light, specifically an amount of light traveling essentially in the same direction, including the possibility of the light beam having a spreading angle or widening angle. The light beam may have a spatial extension. Specifically, the light beam may have a non-Gaussian beam profile. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a
35 conical beam profile. The trapezoid beam profile may have a plateau region and at least one edge region. As used herein, the term "beam profile" generally refers to a transverse intensity profile of the light beam. In particular, the term "beam profile" relates to a spatial distribution, in particular in at least one plane perpendicular to the propagation of the light beam, of an intensity of the light beam. The light beam specifically may be a Gaussian light beam or a linear combination of Gaussian light beams, as will be outlined in further detail below. Other embodiments
40 are feasible, however. The detector may comprise at least one transfer device which may be configured for one or more of adjusting, defining and determining the beam profile, in particular a shape of the beam profile.

The optical sensors of the sensor element may be sensitive in one or more of the ultraviolet, the visible or the infrared spectral range. The optical sensors, specifically, may be sensitive in the infrared spectral range, specifically in the range of 780 nm to 3.0 micrometers, and/or in the visible spectral range, specifically, in the range of 380 nm to 780 nm. Specifically, the optical sensors may be sensitive in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm.

Specifically, the optical sensors may be or may comprise at least one element selected from the group consisting of a CCD sensor element, a CMOS sensor element, a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. Any other type of photosensitive element may be used. As will be outlined in further detail below, the photosensitive element generally may fully or partially be made of inorganic materials and/or may fully or partially be made of organic materials. Most commonly, as will be outlined in further detail below, one or more photodiodes may be used, such as commercially available photodiodes, e.g. inorganic semiconductor photodiodes.

As further used herein, the term "evaluation device" generally refers to an arbitrary device adapted to perform the named operations, preferably by using at least one data processing device and, more preferably, by using at least one processor and/or at least one application-specific integrated circuit. Thus, as an example, the at least one evaluation device may comprise at least one data processing device having a software code stored thereon comprising a number of computer commands. The evaluation device may provide one or more hardware elements for performing one or more of the named operations and/or may provide one or more processors with software running thereon for performing one or more of the named operations.

Specifically, as will be outlined in further detail below, the evaluation device may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between the combined signal and/or any secondary signal derived thereof and the longitudinal coordinate. The combined signal, specifically, as will be outlined in further detail below, may be a quotient signal.

As outlined above, the center signal generally may be a single sensor signal, such as a sensor signal from the optical sensor in the center of the light spot, or may be a combination of a plurality of sensor signals, such as a combination of sensor signals arising from optical sensors in the center of the light spot, or a secondary sensor signal derived by processing a sensor signal derived by one or more of the aforementioned possibilities. The determination of the center signal may be performed electronically, since a comparison of sensor signals is fairly simply implemented by conventional electronics, or may be performed fully or partially by software. Specifically, the center signal may be selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the opti-

cal sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold;
5 an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

10 As outlined above, raw sensor signals of the optical sensors may be used for evaluation or secondary sensor signals derived thereof. As used herein, the term "secondary sensor signal" generally refers to a signal, such as an electronic signal, more preferably an analogue and/or a digital signal, which is obtained by processing one or more raw signals, such as by filtering, averaging, demodulating or the like. Thus, image processing algorithms may be used for generating
15 secondary sensor signals from the totality of sensor signals of the matrix or from a region of interest within the matrix. Specifically, the detector, such as the evaluation device, may be configured for transforming the sensor signals of the optical sensor, thereby generating secondary optical sensor signals, wherein the evaluation device is configured for performing steps a)-d) by
20 using the secondary optical sensor signals. The transformation of the sensor signals specifically may comprise at least one transformation selected from the group consisting of: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image
25 created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency decomposition.; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a
30 Roberts operator; applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be determined manually by a user or maybe determined automatically, such as by recognizing an object within an image generated by the optical sensors. As an example, a vehicle, a person or another type of predetermined object may be determined by automatic image recognition within an image, i.e. within the totality of sensor signals generated by the optical sensors, and the region of interest may be chosen such that the object is located within the region of interest. In this case, the evaluation, such as the determination of the longitudinal coordinate, may be performed for the region of interest, only. Other implementations,
40 however, are feasible.

As outlined above, the detection of the center of the light spot, i.e. the detection of the center signal and/or of the at least one optical sensor from which the center signal arises, may be per-

formed fully or partially electronically or fully or partially by using one or more software algorithms. Specifically, the evaluation device may comprise at least one center detector for detecting the at least one highest sensor signal and/or for forming the center signal. The center detector specifically may fully or partially be embodied in software and/or may fully or partially be embodied in hardware. The center detector may fully or partially be integrated into the at least one sensor element and/or may fully or partially be embodied independently from the sensor element.

As outlined above, the sum signal may be derived from all sensor signals of the matrix, from the sensor signals within a region of interest or from one of these possibilities with the sensor signals arising from the optical sensors contributing to the center signal excluded. In every case, a reliable sum signal may be generated which may be compared with the center signal reliably, in order to determine the longitudinal coordinate. Generally, the sum signal may be selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; an integral of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal. Other options, however, exist.

The summing may be performed fully or partially in software and/or may be performed fully or partially in hardware. A summing is generally possible by purely electronic means which, typically, may easily be implemented into the detector. Thus, in the art of electronics, summing devices are generally known for summing two or more electrical signals, both analogue signals and digital signals. Thus, the evaluation device may comprise at least one summing device for forming the sum signal. The summing device may fully or partially be integrated into the sensor element or may fully or partially be embodied independently from the sensor element. The summing device may fully or partially be embodied in one or both of hardware or software.

As outlined above, the comparison between the center signal and the sum signal specifically may be performed by forming one or more combined signals. Thus, generally, the combined signal may be a quotient signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of the center signal and a linear combination of the sum signal and the center signal or vice versa;

forming a quotient of the sum signal and a linear combination of the sum signal and the center signal or vice versa; forming a quotient of an exponentiation of the center signal and an exponentiation of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal. Other options, however, exist. The evaluation device may be configured for forming the one or more quotient signals. The evaluation device may further be configured for determining the at least one longitudinal coordinate by evaluating the at least one combined signal.

The evaluation device specifically may be configured for using at least one predetermined relationship between the combined signal Q and the longitudinal coordinate, in order to determine the at least one longitudinal coordinate. Thus, due to the reasons disclosed above and due to the dependency of the properties of the light spot on the longitudinal coordinate, the combined signal Q typically is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, a simple quotient of the sensor signal s_{center} and the sum signal s_{sum} $Q = s_{\text{center}}/s_{\text{sum}}$ may be a monotonously decreasing function of the distance. Without wishing to be bound by this theory, it is believed that this is due to the fact that, in the preferred setup described above, both the center signal s_{center} and the sum signal s_{sum} decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, the center signal s_{center} decreases more rapidly than the sum signal s_{sum} , since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. The quotient of the center signal and the sum signal, thus, continuously decreases with increasing diameter of the light beam or diameter of the light spot on the light-sensitive areas of the optical sensors of the matrix. The quotient, further, is typically independent from the total power of the light beam, since the total power of the light beam forms a factor both in the center signal and in the sum sensor signal. Consequently, the quotient Q may form a secondary signal which provides a unique and unambiguous relationship between the center signal and the sum signal and the size or diameter of the light beam. Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship between the center signal and the sum signal on the one hand and the longitudinal coordinate on the other hand may exist. For the latter, reference e.g. may be made to one or more of the above-mentioned prior art documents, such as WO 2014/097181 A1. The predetermined relationship may be determined by analytical considerations, such as by assuming a linear combination of Gaussian light beams, by empirical measurements, such as measurements measuring the combined signal and/or the center signal and the sum signal or secondary signals derived thereof as a function of the longitudinal coordinate of the object, or both.

The evaluation device may be configured for deriving the combined signal Q by one or more of dividing the sum signal and the center signal, dividing multiples of the sum signal and the center

signal, dividing linear combinations of the sum signal and the center signal. For example, the evaluation device may be configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

- 5 wherein x and y are transversal coordinates, A1 and A2 are areas of at least one beam profile at the position of the sensor element, and E(x,y,z_o) denotes the beam profile given at the object distance z_o. Area A1 and area A2 may differ. In particular, A1 and A2 are not congruent. Thus, A1 and A2 may differ in one or more of the shape or content. The center signal may be a sensor signal comprising essentially center information of the beam profile. The sum signal may be a
- 10 signal comprising essentially edge information of the beam profile. The beam profile may be a cross section of the light beam. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles.
- 15 Each of the center signal and the sum signal may comprise at least one information of at least one area of the beam profile of the light beam. As used herein, the term “area of the beam profile” generally refers to an arbitrary region of the beam profile at the position of the sensor element used for determining the combined signal Q. The light-sensitive regions may be arranged such that the sum signal signal comprises information of a first area of the beam profile and the
- 20 center signal comprises information of a second area of the beam profile. The first area of the beam profile and second area of the beam profile may be one or both of adjacent or overlapping regions. The first area of the beam profile and the second area of the beam profile may be not congruent in area.
- 25 The evaluation device may be configured to determine and/or to select the first area of the beam profile and the second area of the beam profile. The first area of the beam profile may comprise essentially edge information of the beam profile and the second area of the beam profile may comprise essentially center information of the beam profile. The beam profile may have a center, i.e. a maximum value of the beam profile and/or a center point of a plateau of the
- 30 beam profile and/or a geometrical center of the light spot, and falling edges extending from the center. The second region may comprise inner regions of the cross section and the first region may comprise outer regions of the cross section. As used herein, the term “essentially center information” generally refers to a low proportion of edge information, i.e. proportion of the intensity distribution corresponding to edges, compared to a proportion of the center information, i.e.
- 35 proportion of the intensity distribution corresponding to the center. Preferably the center information has a proportion of edge information of less than 10 %, more preferably of less than 5%, most preferably the center information comprises no edge content. As used herein, the term “essentially edge information” generally refers to a low proportion of center information com-

pared to a proportion of the edge information. The edge information may comprise information of the whole beam profile, in particular from center and edge regions. The edge information may have a proportion of center information of less than 10 %, preferably of less than 5%, more preferably the edge information comprises no center content. At least one area of the beam profile may be determined and/or selected as second area of the beam profile if it is close or around the center and comprises essentially center information. At least one area of the beam profile may be determined and/or selected as first area of the beam profile if it comprises at least parts of the falling edges of the cross section. For example, the whole area of the cross section may be determined as first region. The first area of the beam profile may be area A2 and the second area of the beam profile may be area A1.

Other selections of the first area A1 and second area A2 may be feasible. For example, the first area may comprise essentially outer regions of the beam profile and the second area may comprise essentially inner regions of the beam profile. For example, the center signal may be a signal corresponding to a rectangular stripe comprising the center of the light spot. The evaluation device may be adapted to form a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal. In particular, in case of a two-dimensional beam profile, the beam profile may be divided in a left part and a right part, wherein the first area may comprise essentially areas of the left part of the beam profile and the second area may comprise essentially areas of the right part of the beam profile. The first and the second area, as an example, may be adjacent, with a minimum separation from one another. However, the separation between adjacent areas may also be varied such as enlarged to improve the dynamic range of the quotient signal. As an example, the separation between two adjacent areas may be increased by not evaluating the area between the first and the second area. This may reduce the light on one of the areas relative and/or absolute as compared to the adjacent area which will may increase a quotient of the signal of the two areas. Further, one or both of the areas may consist of separated subareas which may be adjacent to each other and/or which may be separated by areas that are not evaluated and/or which may be evaluated as part of a different quotient. Further, the first and the second area may consist of a linear combination of subareas, whereas the signal contributed by each subarea may be weighted differently when forming the center signal and/or the sum signal. This may further be beneficial for increasing the dynamic range of the quotient system.

The edge information may comprise information relating to a number of photons in the first area of the beam profile and the center information may comprise information relating to a number of photons in the second area of the beam profile. The evaluation device may be adapted for determining an area integral of the beam profile. The evaluation device may be adapted to determine the edge information by integrating and/or summing of the first area. The evaluation device may be adapted to determine the center information by integrating and/or summing of the second area. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of edge and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determi-

nation of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

Additionally or alternatively, the evaluation device may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized, for example, by replacing the area integrals in the combined signal Q by one or more line integrals along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or cuts may result in an improved distance information.

The evaluation device may be configured to derive the combined signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information. Thus, essentially, photon ratios may be used as the physical basis of the method.

The detector may be adapted to determine depth information, in particular absolute depth information, from a radiance ratio of at least two asymmetric regions of a light beam profile on the at least two optical sensors. For example, the detector may comprise a plurality of optical sensors arranged in a matrix. The detector may be adapted to determine depth information from a radiance ratio of at least two asymmetric regions within an enclosed, in particular, a defocused beam profile captured by a single matrix of optical sensors such as a CMOS detector. In particular, the detector may be adapted to determine the depth information using the radiance ratio. This principle is called Distance by Photon Ratio (DPR).

The DPR principle can be applied, for example, to many sub-regions within a segmented image profile, such as a segmented image of at least one feature generated by the at least one light beam on the matrix of optical sensors, which is demonstrated hereafter. The quotient $Q_A(z)$ in the two-dimensional case can be written as

$$Q_A(z) = \frac{\iint_{-r_{out}}^{r_{out}} P(x,y,z) dx dy}{\iint_{-r_{in}}^{r_{in}} P(x,y,z) dx dy},$$

where $P(x, y, z)$ is a two-dimensional beam profile and r_{in} and r_{out} are inner and outer circle radii, respectively. For line-segmented quotients $Q_y(z)$ along the y-dimension, this can be rewritten as

$$Q_y(z) = \frac{\int_{-r_{out}}^{r_{out}} P(x,z) dx}{\int_{-r_{in}}^{r_{in}} P(x,z) dx}.$$

Without wishing to be bound by this theory, the overall defocused beam profile $P(x, z)$ can be regarded as a superposition of defocused image point profiles $p(x, z)$ along the image width $b(x, z)$. This relationship can be modelled as a convolution given by

$$P(x, z) = b(x, z) * p(x, z),$$

wherein $p(x, z)$ represents the Point-Spread-Function (PSF) of a lens in defocus, which in the field of paraxial optics is also known as Circle of Confusion (CoC). By inserting $P(x, z)$ into $Q_y(z)$ the above described quotient $Q_y(z)$ can be rewritten as

$$Q_y(z) = \frac{\int_{-r_{out}}^{r_{out}} b(x, z) \cdot p(x, z) dx}{\int_{-r_{in}}^{r_{in}} b(x, z) \cdot p(x, z) dx} = \frac{\int_{-r_{out}}^{r_{out}} b(x, z) dx \cdot \int_{-r_{out}}^{r_{out}} p(x, z) dx}{\int_{-r_{in}}^{r_{in}} b(x, z) dx \cdot \int_{-r_{in}}^{r_{in}} p(x, z) dx}.$$

Furthermore, with the matrix of optical sensors a defocused beam profile may be subdivided into cross-sections along lines of a certain angle θ and with a distance ω from the origin of ordinates. Accordingly, the parameterization of a single line may be given by

$$\omega = x \cos(\theta) + y \sin(\theta).$$

The integration of the intensity along parallel lines can be mathematically described by an integral projection $\Re\{\cdot\}$ of the well-known Radon transform which reads

$$\Re_{(\omega, \theta)}\{f(x, y)\} = \iint_{-\infty}^{\infty} f(x, y) \delta(x \cos(\theta) + y \sin(\theta) - \omega) dx dy,$$

where δ denotes the Dirac delta function and $f(x, y)$ is the intensity of an enclosed defocused beam profile. The photon ratio R for a given angle θ and projection width ω is given by

$$R = \frac{\Re_{(\omega, \theta)}\{f'(x, y)\}}{\Re_{(\omega, \theta)}\{f(x, y)\}},$$

with $f'(x, y)$ as the inner region. The variation of θ may yield different ratios R for skewed object surfaces at a certain distance. It is sufficient to let θ vary in the following interval $\{\theta \in \mathbb{R}_+, \theta < \pi\}$.

In one embodiment, the light beam propagating from the object to the detector may illuminate the sensor element with at least one pattern comprising at least one feature point. As used herein, the term “feature point” refers to at least one at least partially extended feature of the pattern. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors. The central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

For example, the light beam propagating from the object to the detector may illuminate the optical sensors with at least one line pattern. The line pattern may be generated by the object, for example in response to an illumination by the at least one illumination source with an illumination pattern comprising the at least one line pattern. A1 may correspond to an area with a full line width of the line pattern on the optical sensors, in particular on the light sensitive area of the optical sensors. The line pattern on the optical sensors may be widened and/or displaced compared to the line pattern of the illumination pattern such that the line width on the optical sensors is increased. In particular, in case of a matrix of optical sensors, the line width of the line pattern on the optical sensors may change from one column to another column. A2 may be a central

area of the line pattern on the optical sensors. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern may be segmented on the optical sensors. Each column of the matrix of optical sensors may comprise center information of intensity in the central area of the line pattern and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern.

For example, the light beam propagating from the object to the detector may illuminate the sensor element with at least one point pattern. The point pattern may be generated by the object, for example in response to an illumination by the at least one light source with an illumination pattern comprising the at least one point pattern. A1 may correspond to an area with a full radius of a point of the point pattern on the optical sensors. A2 may be a central area of the point in the point pattern on the optical sensors. The central area may be a constant value. The central area may have a radius compared to the full radius. For example, the central area may have a radius from 0.1 to 0.9 of the full radius, preferably from 0.4 to 0.6 of the full radius.

The light beam propagating from the object to the detector may illuminate the sensor element with a reflection pattern comprising both point patterns and line patterns. Other embodiments in addition or alternatively to line pattern and point pattern are feasible.

Thus, generally, the evaluation device may be configured for determining the longitudinal coordinate by evaluating the combined signal such as the combined signal Q. This determining may be a one-step process, such as by directly combining the center signal and the sum signal and deriving the longitudinal coordinate thereof, or may be a multiple step process, such as by firstly deriving the combined signal from the center signal and the sum signal and, secondly, by deriving the longitudinal coordinate from the combined signal. Both options, i.e. the option of steps c) and d) being separate and independent steps and the option of steps c) and d) being fully or partially combined, shall be comprised by the present invention.

The evaluation device may be configured for using at least one predetermined relationship between the combined signal and the longitudinal coordinate. The predetermined relationship may be one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship. The evaluation device may comprise at least one data storage device for storing the predetermined relationship, such as a lookup list or a lookup table.

The combined signal Q may be determined by using various means. As an example, a software means for deriving the combined signal, a hardware means for deriving the combined signal, or both, may be used and may be implemented in the evaluation device. Thus, the evaluation device, as an example, may comprise at least one divider, wherein the divider is configured for deriving the combined signal. The divider may fully or partially be embodied as one or both of a software divider or a hardware divider. The divider may fully or partially be integrated into the

sensor element answers or may fully or partially be embodied independent from the sensor element.

As outlined above, the optical sensors specifically may be or may comprise photodetectors, preferably inorganic photodetectors, more preferably inorganic semiconductor photodetectors, most preferably silicon photodetectors. Specifically, the optical sensors may be sensitive in the infrared spectral range. All of the optical sensors of the matrix or at least a group of the optical sensors of the matrix specifically may be identical. Groups of identical optical sensors of the matrix specifically may be provided for different spectral ranges, or all optical sensors may be identical in terms of spectral sensitivity. Further, the optical sensors may be identical in size and/or with regard to their electronic or optoelectronic properties.

Specifically, the optical sensors may be or may comprise inorganic photodiodes which are sensitive in the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers. Specifically, the optical sensors may be sensitive in the part of the near infrared region where silicon photodiodes are applicable specifically in the range of 700 nm to 1000 nm. Infrared optical sensors which may be used for optical sensors may be commercially available infrared optical sensors, such as infrared optical sensors commercially available from Hamamatsu Photonics Deutschland GmbH, D-82211 Herrsching am Ammersee, Germany. Thus, as an example, the optical sensors may comprise at least one optical sensor of an intrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge photodiode, an InGaAs photodiode, an extended InGaAs photodiode, an InAs photodiode, an InSb photodiode, a HgCdTe photodiode. Additionally or alternatively, the optical sensors may comprise at least one optical sensor of an extrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge:Au photodiode, a Ge:Hg photodiode, a Ge:Cu photodiode, a Ge:Zn photodiode, a Si:Ga photodiode, a Si:As photodiode. Additionally or alternatively, the optical sensors may comprise at least one bolometer, preferably a bolometer selected from the group consisting of a VO bolometer and an amorphous Si bolometer.

The matrix may be composed of independent optical sensors. Thus, a matrix of inorganic photodiodes may be composed. Alternatively, however, a commercially available matrix may be used, such as one or more of a CCD detector, such as a CCD detector chip, and/or a CMOS detector, such as a CMOS detector chip.

Thus, generally, the optical sensors of the detector may form a sensor array or may be part of a sensor array, such as the above-mentioned matrix. Thus, as an example, the detector may comprise an array of optical sensors, such as a rectangular array, having m rows and n columns, with m , n , independently, being positive integers. Preferably, more than one column and more than one row is given, i.e. $n > 1$, $m > 1$. Thus, as an example, n may be 2 to 16 or higher and m may be 2 to 16 or higher. Preferably, the ratio of the number of rows and the number of columns is close to 1. As an example, n and m may be selected such that $0.3 \leq m/n \leq 3$, such as by choosing $m/n = 1:1, 4:3, 16:9$ or similar. As an example, the array may be a square array,

having an equal number of rows and columns, such as by choosing $m=2$, $n=2$ or $m=3$, $n=3$ or the like.

As further outlined above, the matrix specifically may be a rectangular matrix having at least one row, preferably a plurality of rows, and a plurality of columns. As an example, the rows and columns may be oriented essentially perpendicular, wherein, with respect to the term “essentially perpendicular”, reference may be made to the definition given above. Thus, as an example, tolerances of less than 20° , specifically less than 10° or even less than 5° , may be acceptable. In order to provide a wide range of view, the matrix specifically may have at least 10 rows, preferably at least 50 rows, more preferably at least 100 rows. Similarly, the matrix may have at least 10 columns, preferably at least 50 columns, more preferably at least 100 columns. The matrix may comprise at least 50 optical sensors, preferably at least 100 optical sensors, more preferably at least 500 optical sensors. The matrix may comprise a number of pixels in a multi-mega pixel range. Other embodiments, however, are feasible. Thus, as outlined above, in setups in which an axial rotational symmetry is to be expected, circular arrangements or concentric arrangements of the optical sensors of the matrix, which may also be referred to as pixels, may be preferred.

As further outlined above, preferably, the sensor element may be oriented essentially perpendicular to an optical axis of the detector. Again, with respect to the term “essentially perpendicular”, reference may be made to the definition and the tolerances given above. The optical axis may be a straight optical axis or may be bent or even split, such as by using one or more deflection elements and/or by using one or more beam splitters, wherein the essentially perpendicular orientation, in the latter cases, may refer to the local optical axis in the respective branch or beam path of the optical setup.

The matrix may comprise two or four separate light sensitive areas and/or may be sub-divided into two or more segments, in particular two or four active areas. The light sensitive areas and/or segments may be separated by a dividing line. The dividing line, for example, of two Si-diodes, can be arranged parallel to the baseline of the detector, in particular parallel to a spot movement on the optical sensors. However, other arrangements are feasible. For example, the quadrant diode may comprise at least two dividing lines. The at least two dividing lines may be arranged orthogonal to each other. The orthogonal arrangement of the dividing lines allows adjusting of the combined signal for near field and far field applications independently from each other. In addition to determining the combined signal of sum signal and center signal, the evaluation device may be adapted to determine a second quotient using other signals of the matrix. The two quotients can be formed such that two distinct distance ranges are covered. The two quotient signals for the near field and far field may have an overlap region in which both quotient signals allow obtaining reasonable determination of the longitudinal distance z . For example, the quotient signal may be determined by dividing the sensor signals of two top quadrants, also called top segment, by the sensor signals of two bottom quadrants, also called bottom segment. Using the quotient signal of sensor signals determined by two sensor areas which have a dividing line parallel to the baseline of the detector may allow determining of the quotient

without any distance dependent movement of the light spot. In particular, as an example, if the dividing line between the top and bottom segment is parallel to the baseline, the quotient signal determined from top segment divided by bottom segment may be used in the near field, wherein the light spot may illuminate only one of a left or right segment of the quadrant diode. In this case determining the quotient signal by dividing sensor signals of the left and right segments may not be possible. However, determining the quotient by dividing the sensor signals of top and bottom segments may provide a reasonable distance measurement. The quotient signal determined by dividing sensor signals of the left and right segments may be used for far field measurement, wherein the light spot illuminates both left and right segments. Furthermore, the evaluation device may be adapted to determine the quotient signal by dividing sensor signals of opposing segments or neighboring segments. The evaluation device may be adapted to combine the acquired sensor signals of the quadrants such that distance measurement is possible over a wide range with a large resolution.

In view of the technical challenges involved in the prior art documents discussed above, specifically in view of the technical effort which is required for generating the FiP effect, it has to be noted that the present invention specifically may be realized by using non-FiP optical sensors. In fact, since optical sensors having the FiP characteristic typically exhibit a strong peak in the respective sensor signals at a focal point, the range of measurement of a detector according to the present invention using FiP sensors as optical sensors may be limited to a range in between the positions and which the optical sensors are in focus of the light beam. When using linear optical sensors, however, i.e. optical sensors not exhibiting the FiP effect, this problem, with the setup of the present invention, generally may be avoided. Consequently, the optical sensors each may have, at least within a range of measurement, a linear signal characteristic such that the respective sensor signals are dependent on the total power of illumination of the respective optical sensor.

The detector may further comprise an illumination source for illuminating the object. As an example, the illumination source may be configured for generating an illuminating light beam for illuminating the object. The detector may be configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector. For this purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

As outlined above, the illumination source, specifically, may be configured for emitting light in the infrared spectral range. It shall be noted, however, that other spectral ranges are feasible, additionally or alternatively. Further, the illumination source, as outlined above, specifically may be configured for emitting modulated or non-modulated light. In case a plurality of illumination sources is used, the different illumination sources may have different modulation frequencies which, as outlined in further detail below, later on may be used for distinguishing the light beams. The illumination source may be adapted to generate and/or to project a cloud of points, for example the illumination source may comprise one or more of at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at

least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources.

5 The detector may comprise the at least one illumination source. The illumination source may be adapted to illuminate the object with at least one illumination light beam. The illumination light beam may be fully or partially reflected by the object and may travel back towards the detector. The illumination source may be arranged such that a direction of propagation of the illumination light beam is essentially parallel to the optical axis. As used herein, the term “essentially parallel to the optical axis” refers to the condition of a parallel orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less. The illumination source may be arranged such that a line running in the direction of propagation of the illumination light beam and the optical axis do not intersect in space. In particular, the illumination may be on-axis. In order to provide such an on-axis illumination, as an example, one or more reflective elements may be used, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms. The reflected light beam may be essentially parallel to the optical axis. Thus, according to the present invention, the object distance is not determined from an angle of the light beam, i.e. a position of the light spot on a sensor, as done in triangulation methods. Instead, the object distance may be determined using light beams essential parallel to the optical axis. Determination of the object distance by a non-triangulation method but by combining the at least two sensor signals, allows arranging the illumination source such that the direction of propagation of the illumination light beam is essentially parallel to the optical axis.

25 The light beam may be a monochromatic light beam. The light beam may comprise a narrow band of wavelengths, preferably the light beam may comprise a single wavelength. The at least one light source may be adapted to generate at least one monochromatic light beam and/or the detector may comprise at least one filter element adapted to filter a narrow band of wavelength, such as a monochromator.

30 The illumination source may be adapted to generate at least one illumination pattern for illuminating the object. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. The detector may be configured such that the illumination pattern propagates from the detector, in particular from at least one opening of the housing, towards the object along and/or parallel to an optical axis of the detector. For this purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illumination pattern such that it propagates along or parallel to the optical axis. Specifically, the illumination source may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. As used herein, the term “pattern” refers to an arbitrary known or pre-determined arrangement comprising at least one arbitrarily shaped feature. The pattern may comprise at least one feature such as a point or symbol. The pattern may comprise a plurality of features. The pattern may comprise an arrangement of periodic or non-periodic features. As used herein, the term “illumination pattern” refers to a pat-

tern which illuminates the object. The illumination pattern may be generated by ambient light, such as by at least one ambient light source, or by the at least one illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern, a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines; at least one fringe pattern. For example, the illumination source may be adapted to generate and/or to project a cloud of points. The illumination pattern may comprise regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern, or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that a hexagonal pattern may be preferred. A distance between two features of the illumination pattern and/or an area of the at least one illumination feature may depend on the circle of confusion in the image.

The illumination source may comprise one or more of at least one light projector; at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The illumination source may comprise at least one light source adapted to generate the illumination pattern directly. For example, the illumination source may comprise at least one laser source. For example, the illumination source may comprise at least one line laser. The line laser may be adapted to send a laser line to the object, for example a horizontal or vertical laser line. The illumination source may comprise a plurality of line lasers. For example, the illumination source may comprise at least two line lasers which may be arranged such that the illumination pattern comprises at least two parallel or crossing lines. The illumination source may comprise the at least one light projector adapted to generate a cloud of points such that the illumination pattern may comprise a plurality of point pattern. The illumination source may comprise at least one mask adapted to generate the illumination pattern from at least one light beam generated by the illumination source. The illumination source may be one of attached to or integrated into a mobile device such as a smartphone. The illumination source may be used for further functions that may be used in determining an image such as for an autofocus function. The illumination source may be attached to a mobile device such as by using a connector such as a USB- or phone-connector such as the headphone jack.

The illumination source may be adapted to generate pulsed illumination. The illumination source may be adapted to generate at least one light pulse. As used herein, the term "light pulse" or "pulsed illumination" refers to a light beam limited in time. The light pulse may have a predefined length or time duration, for example in the nanoseconds range. For example, the illumination source may be adapted to generate pulses with a pulse length of less than a nanosecond, such as a tenth of a nanosecond, up to a tenth of a second. The illumination source may

be adapted to periodically generate the light pulse. For example, the illumination source may be adapted to generate the light pulse with a frequency of 10 Hz to 10 GHz.

5 The illumination source may be adapted to generate a pulsed light beam. For example, the illumination source may be adapted to generate a continuous illumination light beam and the detector may comprise at least one interruption device adapted to interrupt the illumination, in particular periodically. The interruption device may comprise at least one shutter and/or a beam chopper or some other type of mechanical or electronical periodic beam interrupting device, for example comprising at least one interrupter blade or interrupter wheel, which preferably rotates
10 at constant speed and which can thus periodically interrupt the illumination. By way of example, the at least one interruption device can also be wholly or partly integrated into the illumination source. Various possibilities are conceivable.

15 Preferably, the illumination source may be a movable and/or mobile illumination source. For example, the illumination source may be moved during the measurement such as to illuminate the object from different positions and/or angles. However, embodiments are feasible in which the illumination source may be positioned in at least one fixed position, for example during a complete measurement time. The evaluation device may be adapted to illumination sources with unclear position such as due to high manufacturing tolerances and/or user interaction
20 and/or user assembly or the like.

The illumination source may illuminate the object with a convergent and/or divergent and/or collimated light beam.

25 The illumination source and the sensor element may be arranged in a common plane or in different planes. The illumination source and the optical sensors may have different spatial orientation. In particular, the illumination source and the optical sensors may be arranged in a twisted arrangement.

30 The illumination source and the optical axis may be separated by a small baseline. As used herein, the term "baseline", also denoted as basis line, refers to a distance, for example in a xy - plane, between the optical axis and the illumination source, in particular a distance between the optical axis and a z-component of the illumination light beam. The illumination source may be spaced apart from the optical axis by a minimum distance. The minimum distance from the optical axis may be defined by further detector elements such as size and position of the optical
35 sensors and transfer device. The baseline may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. For example, the baseline may be 21 mm. For example, the detector may be a compact device without further optical elements, wherein the illumination source may be placed as close as possible to an edge of the transfer device. Thus, the baseline
40 may be close to half a diameter of the transfer device, in particular the lens diameter and housings of lens and light source. For example, the detector may be an even more compact device, wherein a mirror, in particular a small mirror, may be positioned in front of the transfer device, in particular in a center, for example a geometrical center, or close to the center of the transfer

device, in order to couple the illumination beam into the beam path. Thus, the baseline may be less than half the diameter of the transfer device. The illumination source may be arranged such that the baseline is as small as possible. By arranging the illumination source such that the direction of propagation of the illumination light beam is essentially parallel to the optical axis and that the illumination source and the optical axis are separated by the small baseline, very compact devices are possible. For example, a distance from the center of the transfer device to the illumination source, in particular along a connecting line from the center of the transfer device to the illumination source, may be preferably less than 2.5 times a distance from the center of the transfer device to an edge if the transfer device, more preferably less than 1.5 times the distance center to edge of the transfer device, and most preferably less 1 times the distance center to edge of the transfer device. The transfer device may have an arbitrary shape, in particular a non-circular shapes are possible. At small distances an aperture of the illumination source may be small and the baseline may be small. At large distances an aperture of the illumination source may be large and the baseline may be small. This is contrarily as in triangulation methods, wherein at large distances a large baseline is necessary. Further, triangulation based systems have a minimum detection range significantly greater than zero, for example such as 20 cm from the detector system, due to necessary spatial extent of the baseline. Such a large baseline may result in that the illuminated light scattered from the object may not reach the light sensitive area of the optical sensor behind the transfer device. In addition, in triangulation based systems, using a small baseline would reduce the minimum detection range, however, at the same time would reduce a maximum detection range. Further, triangulation based systems require a plurality of light sensitive areas and sensor signals, for example sensor signals of at least one detector row. According to the invention, determination of the longitudinal coordinate z is possible with a reduced number of sensor signals, in particular with less than 20, preferably less than 10 and more preferably less than 5 sensor signals.

The detector may further comprise at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensors. The transfer device specifically may comprise one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

The optical sensor may be positioned off focus. As used herein, the term "focus" generally refers to one or both of a minimum extent of a circle of confusion of the light beam, in particular of at least one light beam emitted from one point of the object, caused by the transfer device or a focal length of the transfer device. As used herein, the term "circle of confusion" refers to a light spot caused by a cone of light rays of the light beam focused by the transfer device. The circle of confusion may depend on a focal length f of the transfer device, a longitudinal distance from the object to the transfer device, a diameter of an exit pupil of the transfer device, a longitudinal distance from the transfer device to the light sensitive area, a distance from the transfer device

to an image of the object. For example, for Gaussian beams, a diameter of the circle of confusion may be a width of the Gaussian beam. In particular, for a point like object situated or placed at infinite distance from the detector the transfer device may be adapted to focus the light beam from the object into a focus point at the focal length of the transfer device. For non-point like objects situated or placed at infinite distance from the detector the transfer device may be adapted to focus the light beam from at least one point of the object into a focus plane at the focal length of the transfer device. For point like objects not situated or placed at infinite distance from the detector, the circle of confusion may have a minimum extent at least at one longitudinal coordinate. For non-point like objects not situated or placed at infinite distance from the detector, the circle of confusion of the light beam from at least one point of the object may have a minimum extent at least at one longitudinal coordinate. As used herein, the term "positioned off focus" generally refers to a position other than the minimum extent of a circle of confusion of the light beam caused by the transfer device or a focal length of the transfer device. In particular, the focal point or minimum extent of the circle of confusion may be at a longitudinal coordinate l_{focus} , whereas the position of the optical sensor may have a longitudinal coordinate l_{sensor} different from l_{focus} . For example, the longitudinal coordinate l_{sensor} may be, in a longitudinal direction, arranged closer to the position of the transfer device than the longitudinal coordinate l_{focus} or may be arranged further away from the position of the transfer device than the longitudinal coordinate l_{focus} . Thus, the longitudinal coordinate l_{sensor} and the longitudinal coordinate l_{focus} may be situated at different distances from the transfer device. For example, the optical sensors may be spaced apart from the minimum extent of the circle of confusion in longitudinal direction by $\pm 2\%$ focal length, preferably by $\pm 10\%$ focal length, most preferably $\pm 20\%$ focal length. For example, at a focal length of the transfer device may be 20mm and the longitudinal coordinate l_{sensor} may be 19,5 mm, i.e. the optical sensor may be positioned at 97,5% focal length, such that l_{sensor} is spaced apart from the focus by 2,5% of focal length. The extent of the circle of confusion may be larger than the extent of the optical sensor. For example, the optical sensor may be positioned as such that the circle of confusion extends beyond the optical sensor. The optical sensor may thus only partially evaluate the beam profile of the light beam. The evaluation device may be adapted to extrapolate a beam profile such as due to symmetry considerations or due to comparing the partial beam profile to prerecorded beam profiles or the like. Further, the evaluation device may be adapted to evaluate a partial sum signal and a partial center signal of a partial beam profile and convert it into a sum signal and a center signal of an extrapolated and/or fitted and/or prerecorded beam profile or the like.

The above-mentioned operations, including determining the at least one longitudinal coordinate of the object, are performed by the at least one evaluation device. Thus, as an example, one or more of the above-mentioned relationships may be implemented in software and/or hardware, such as by implementing one or more lookup tables. Thus, as an example, the evaluation device may comprise one or more programmable devices such as one or more computers, application-specific integrated circuits (ASICs), Digital Signal Processors (DSPs), or Field Programmable Gate Arrays (FPGAs) which are configured to perform the above-mentioned evaluation, in order to determine the at least one longitudinal coordinate of the object. Additionally or alternatively, however, the evaluation device may also fully or partially be embodied by hardware.

As outlined above, by evaluating the center signal and the sum signal, the detector may be enabled to determine the at least one longitudinal coordinate of the object, including the option of determining the longitudinal coordinate of the whole object or of one or more parts thereof. In addition, however, other coordinates of the object, including one or more transversal coordinates and/or rotational coordinates, may be determined by the detector, specifically by the evaluation device. Thus, as an example, one or more transversal sensors may be used for determining at least one transversal coordinate of the object. As outlined above, the position of the at least one optical sensor from which the center signal arises may provide information on the at least one transversal coordinate of the object, wherein, as an example, a simple lens equation may be used for optical transformation and for deriving the transversal coordinate. Additionally or alternatively, one or more additional transversal sensors may be used and may be comprised by the detector. Various transversal sensors are generally known in the art, such as the transversal sensors disclosed in WO 2014/097181 A1 and/or other position-sensitive devices (PSDs), such as quadrant diodes, CCD or CMOS chips or the like. Additionally or alternatively, as an example, the detector according to the present invention may comprise one or more PSDs disclosed in R.A. Street (Ed.): *Technology and Applications of Amorphous Silicon*, Springer-Verlag Heidelberg, 2010, pp. 346-349. Other embodiments are feasible. These devices may generally also be implemented into the detector according to the present invention. As an example, a part of the light beam may be split off within the detector, by at least one beam splitting element. The split-off portion, as an example, may be guided towards a transversal sensor, such as a CCD or CMOS chip or a camera sensor, and a transversal position of a light spot generated by the split-off portion on the transversal sensor may be determined, thereby determining at least one transversal coordinate of the object. Consequently, the detector according to the present invention may either be a one-dimensional detector, such as a simple distance measurement device, or may be embodied as a two-dimensional detector or even as a three-dimensional detector. Further, as outlined above or as outlined in further detail below, by scanning a scenery or an environment in a one-dimensional fashion, a three-dimensional image may also be created. Consequently, the detector according to the present invention specifically may be one of a one-dimensional detector, a two-dimensional detector or a three-dimensional detector. The evaluation device may further be configured to determine at least one transversal coordinate x , y of the object. The evaluation device may be adapted to combine the information of the longitudinal coordinate and the transversal coordinate and to determine a position of the object in space.

The detector may be configured for evaluating a single light beam or a plurality of light beams. In case a plurality of light beams propagates from the object to the detector, means for distinguishing the light beams may be provided. Thus, the light beams may have different spectral properties, and the detector may comprise one or more wavelength selective elements for distinguishing the different light beams. Each of the light beams may then be evaluated independently. The wavelength selective elements, as an example, may be or may comprise one or more filters, one or more prisms, one or more gratings, one or more dichroitic mirrors or arbitrary combinations thereof. Further, additionally or alternatively, for distinguishing two or more light beams, the light beams may be modulated in a specific fashion. Thus, as an example, the

light beams may be frequency modulated, and the sensor signals may be demodulated in order to distinguish partially the sensor signals originating from the different light beams, in accordance with their demodulation frequencies. These techniques generally are known to the skilled person in the field of high-frequency electronics. Generally, the evaluation device may be configured for distinguishing different light beams having different modulations.

The illumination source may be adapted to generate and/or to project a cloud of points such that a plurality of illuminated regions is generated on the matrix of optical sensor, for example the CMOS detector. Additionally, disturbances may be present on the matrix of optical sensor such as disturbances due to speckles and/or extraneous light and/or multiple reflections. The evaluation device may be adapted to determine at least one region of interest, for example one or more pixels illuminated by the light beam which are used for determination of the longitudinal coordinate of the object. For example, the evaluation device may be adapted to perform a filtering method, for example, a blob-analysis and/or object recognition method.

As outlined above, the detector may comprise the at least one illumination source. A distance perpendicular to an optical axis of the detector between the illumination source and the optical sensors may be small. The distance perpendicular to the optical axis of the detector between the illumination source and the optical sensors may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. The illumination source and the optical axis may be separated by a small baseline. The illumination source may be spaced apart from the optical axis by a minimum distance. The minimum distance from the optical axis may be defined by further detector elements such as size and position of the optical sensors and of the at least one optional transfer device, which will be described in detail below. The baseline may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. For example, the baseline may be 21 mm. Preferably, the illumination source may be arranged right next to the transfer device. For example, the transfer device may be flattened such that the illumination source can be positioned even closer to the optical axis. The illumination source may be arranged behind the transfer device.

At least one of the optical sensors may be adapted to generate at least one sensor signal dependent on a time-of-flight (TOF) the illumination light beam has traveled from the illumination source to the object and the reflection light beam has traveled from the object to the light sensitive area of the optical sensor. The evaluation device may be configured for determining at least one TOF-longitudinal coordinate z_{TOF} of the object by evaluating the TOF sensor signal. The optical sensor adapted to generate the TOF sensor signal may be designed as time-of-flight detector. The time-of-flight detector may be selected from the group consisting of: at least one pulsed time-of-flight detector; at least one phase modulated time-of-flight detector; at least one direct time-of-flight detector; at least one indirect time-of-flight detector. For example, the pulsed time-of-flight detector may be at least one range gated imager and/or at least one direct time-of-flight imager. For example the phase modulated time-of-flight detector may be at least one RF-modulated light source with at least one phase detector. The optical sensor may be adapted to

determine a time delay between emission of the illumination light beam by the illumination source and receipt of the reflection light beam.

For example, the optical sensor adapted to generate the TOF sensor signal may be designed as pulsed time-of-flight detector. The detector may comprise the at least one interruption device, such as at least one shutter element, adapted to generate a pulsed light beam. The optical sensor may be adapted to store the TOF sensor signal dependent on the receiving time of the reflection light beam in a plurality of time windows, in particular subsequent time windows. The optical sensor may be adapted to store dependent on receiving time of the reflection light beam the generated TOF sensor signal in at least one first time window and/or in at least one second time window. The first and second time windows may be correlated with the opening and closure of the interruption device. Duration of first and second time windows may be pre-defined. For example, the TOF sensor signal may be stored in the first time window during opening of the interruption device, whereas during closure of the interruption device the TOF sensor signal may be stored in the second time window. Other durations of time windows are thinkable. The first and the second time window may comprise information about background, signal height and signal shift.

For example, the optical sensor adapted to generate the TOF sensor signal may be designed as direct time-of-flight imager. The direct time-of-flight imager may comprise the at least one illumination source adapted to generate at least one single laser pulse. The single laser pulse may be reflected back from the object onto the optical sensor. The optical sensor may comprise at least one photodiode, for example at least one Avalanche Photo Diode (APD), such as at least one Si APD, or such as at least one InGaAs APD, or at least one PIN photo detector array, or at least one Single-Photon Avalanche Photodiode (SPAD), adapted to image the reflection light beam. The direct time-of flight imager may be adapted to image at least one image comprising spatial and temporal data.

For example, the optical sensor adapted to generate the TOF sensor signal may be designed as phase modulated time-of-flight modulator. The phase modulated time-of-flight modulator may be adapted to measure a difference in phase, in particular a phase shift, by determining a correlated signal, for example by multiplying a received signal, i.e. of the reflection light beam, with the emitted signal, i.e. the illumination light beam. A DC component of the correlated signal may comprise an information about the difference in phase. The evaluation device may be adapted to determine the second longitudinal coordinate of the object from the phase difference. For example, the illumination source and the optical sensor adapted to generate the TOF sensor signal may be designed as RF-modulated light source with at least one phase detector. The illumination source may comprise, for example, at least one LED and/or at least one laser. The illumination source may comprise at least one modulation device adapted to modulate the light beam having a pre-defined phase shift. For example, the modulation device may comprise at least one radio frequency module. The radio frequency module may be adapted to modulate the illumination beam with an RF carrier. The optical sensor may be adapted to determine a phase shift of the reflective light beam impinging on the optical sensor.

The optical sensor may be designed as and/or may comprise at least one time-of-flight pixel. Preferably, the detector may comprise at least two optical sensors, wherein each optical sensor is designed as and/or comprises at least one TOF pixel. For example, the detector, in particular the optical sensor may comprise a quadrant diode adapted to generate the TOF sensor signal.

5 For example, the detector, in particular the optical sensor, may comprise at least one pixelated TOF-imager.

The evaluation device may be configured for determining the at least one TOF longitudinal coordinate z_{TOF} of the object by evaluating the TOF sensor signal. As used herein, the term “TOF longitudinal coordinate” refers to a longitudinal coordinate derived from the TOF sensor signal. As described above, the illumination light source may be adapted to periodically generate at least one light pulse. The detector may be adapted to generate the first longitudinal sensor signal for each period. The evaluation device may be adapted to determine in which pulse period the TOF sensor signal was generated using the second longitudinal coordinate. The detector
10 may be adapted to uniquely assign to which period the ToF-signal refers to by using the combined sensor signal. Both, the TOF sensor signal and the combined sensor signal, may be non-monotonous functions of the longitudinal coordinate z_{real} . Thus, the longitudinal coordinate may not be uniquely determined from one of the TOF sensor signal or the combined sensor signal alone and a measurement range may not be restricted to a longitudinal range in which the signals are unique functions of z_{real} . The term “measurement range” generally refers to a range
20 from the object to the detector in which determination of the longitudinal coordinate is possible. The term “longitudinal range” generally refers to a range from the object to the detector in which unique determination of the longitudinal coordinate is possible. Below and/or above certain distances from the object to the detector a determination of the longitudinal coordinate may not be possible. For example, time-of-flight measurements are not possible below a certain distance from the object to the detector, possibly due to the minimum measurement time of the internal clock. Furthermore, in time-of-flight measurements the sensor signal may be unique within a longitudinal period, but the sensor signal may be the same in case integer multiples of the longitudinal period are added such that the determined longitudinal coordinate may be non-unique.
30 Thus, the same TOF sensor signal will be obtained for a distance z_1 and a distance $z_1 + n \cdot z_{1p}$, where n is an integer denoting the longitudinal period and z_{1p} is the longitudinal period of the TOF sensor signal, wherein the distances z_1 and $z_1 + n \cdot z_{1p}$ are within the measurement range. As used herein, the term “longitudinal period” refers to partitions of a period, in particular a distance range, in which the longitudinal coordinate can be unambiguously determined from the
35 TOF sensor signal. Non-unique longitudinal coordinates may be denoted as relative longitudinal coordinates and the unique longitudinal coordinates may be denoted as absolute longitudinal coordinates.

If both the TOF sensor signal $F1$ and the combined sensor signals $F2$ are available, it may be
40 possible to uniquely determine the longitudinal coordinate and to extend the longitudinal range, as long as each signal pair ($F1, F2$) corresponds to a unique distance and vice versa. In particular, if a unique signal pair ($F1, F2$) exists for each longitudinal coordinate and vice versa, the evaluation device may be adapted to determine the unique combined longitudinal coordinate by

(1) selecting at least one first selected signal such as the TOF sensor signal and/or the combined sensor signal and determining non-unique first longitudinal coordinates;

(2) selecting a second selected signal such as the combined signal Q and/or the TOF sensor signal, which was not selected in step (1), and determining non-unique second longitudinal coordinates;

(3) determining whether one of the non-unique first longitudinal coordinates and the non-unique second longitudinal coordinates match up to a predetermined tolerance threshold;

(4) setting a combined unique longitudinal coordinate to be a matching longitudinal coordinate.

In step (1) and step (2), signals may be selected in the given order or may be performed in a different order. For example, in step (1) the TOF sensor signal may be selected and in step (2) the combined signal Q may be selected. In another example, in step (1) the combined sensor signal may be selected, and the non-unique first longitudinal sensor signal may be determined therefrom. In step (2), the TOF sensor signal may be selected.

Additionally or alternatively to step (4), the evaluation device may be adapted to output an error signal in case no matching coordinates are found and/or to output an error signal in case more than one matching coordinates are found. Additionally or alternatively, the signal pairs and their corresponding longitudinal coordinates may be stored in a look-up table. Additionally or alternatively, the signal pairs and their corresponding longitudinal coordinates may be approximated or described by an analytical function which is evaluated to find the longitudinal coordinate corresponding to a given signal pair.

The evaluation device may comprise at least two memory elements. As used herein, the term “memory element” refers to a device adapted to store information. The evaluation device may be adapted to receive and to store information provided by the optical sensors, for example the at least one first sensor signal. Such information may comprise raw sensor data and/or processed sensor data. For example, the memory element may be adapted to store information for further evaluation by the evaluation device. The memory element may be a volatile or non-volatile memory element.

As described above, the optical sensor may be designed as and/or may comprise at least one ToF pixel. The detector may comprise at least two switches. Each of the switches may be connected to the optical sensor adapted to generate the first sensor signal, for example by at least one connector. In particular, each of the switches may be connected to the ToF pixel. The switches are adapted to provide the TOF sensor signal to one of the memory elements. In particular, the switches may be adapted to let, dependent on receiving time of the reflection light beam, the generated TOF sensor signal pass through one of the switches. For example, the TOF sensor signal may pass one of the switches during opening of the interruption device, whereas during closure of the interruption device the TOF sensor signal may pass the other switch. Each of the switches may be controlled by a control signal having a pulse length identical to a pulse length of a light pulse generated by the illumination source. The control signal of one of the switches may be delayed. For example, the delay may correspond to the pulse

length of the light pulse. The evaluation device may be adapted to sample and/or store depending on the delay a first part, or fraction, of the TOF sensor signal through a first switch in a first memory element and the other, second part, or fraction, of the TOF sensor signal through a second switch in a second memory element. The evaluation device may be adapted to determine the first longitudinal coordinate by evaluating the first part and second part of the TOF sensor signal. The evaluation device may be adapted to determine the first longitudinal coordinate z_1 by

$$z_1 = \frac{1}{2} \cdot c \cdot t_0 \cdot \frac{S_{12}}{S_{11} + S_{12}} + z_0;$$

wherein c is the speed of light, t_0 is the pulse length of the illumination light beam, z_0 is a distance offset often determined by the resolution of the time measurement, and S_{11} and S_{12} are the first part and second part of the TOF sensor signal, respectively.

The detector may be adapted to determine at least one distance information of the object by using triangulation and/or structured light techniques. In known 3D sensing devices, such as devices using triangulation or structured light techniques, due to correspondence problems regular, constant or periodic pattern are not suitable since each measured point has to be assigned to one reference point of a reference pattern. The at least one light beam propagating from the object to the detector may be adapted to generate at least one reflection pattern on the matrix of optical sensors. The term "reflection pattern" refers to at least one image determined by the optical sensors in response to illumination of the light sensitive areas by the light beam propagating from the object to the detector which was generated in response to illumination by the illumination pattern. The reflection pattern may comprise at least one reflection feature depending on the corresponding illumination feature of the illumination pattern. The detector may be adapted to determine the longitudinal coordinate of an object point for at least one reflection feature of the reflection pattern from the quotient signal. Thus, the detector may be adapted to pre-classify the at least one reflection feature of the reflection pattern. This allows using illumination patterns comprising regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern or a pattern comprising further convex tilings. The illumination pattern may comprise as much as possible features per area such that hexagonal patterns may be preferred.

The evaluation device may be adapted to perform at least one image analysis and/or image processing in order to identify the reflection feature. The image analysis and/or image processing may use at least one feature detection algorithm. The image analysis and/or image processing may comprise one or more of the following: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a decomposition into color channels; a decomposition into hue; saturation; and brightness channels; a frequency decomposition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator;

applying a Kirsch operator; applying a high-pass filter; applying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image. The region of interest may be determined manually by a user or may be determined automatically, such as by recognizing an object within an image generated by the optical sensors.

The evaluation device may be adapted to determine at least one reference feature in at least one reference pattern corresponding to the at least one reflection feature. The term "reference pattern" refers to an image of comparison at a specific spatial position comprising at least one reference feature. As outlined above, the evaluation device may be adapted to perform an image analysis and to identify features of the reflection pattern. The evaluation device may be adapted to identify at least one reference feature in the reference pattern having an essentially identical longitudinal coordinate as the selected reflection feature. The term "essentially identical" refers to identical within 10%, preferably 5%, most preferably 1%. The reference feature corresponding to the reflection feature may be determined using epipolar geometry. For description of epipolar geometry reference is made, for example, to chapter 2 in X. Jiang, H. Bunke: „Dreidimensionales Computersehen“ Springer, Berlin Heidelberg, 1997. Epipolar geometry may assume that the reference pattern and the reflection pattern may be images of the object determined at different spatial positions and/or spatial orientations having a fixed distance. The distance may be a relative distance, also denoted as baseline. The evaluation device may be adapted to determine an epipolar line in the reference pattern. The relative position of the reference pattern and reflection pattern may be known. For example, the relative position of the reference pattern and the reflection pattern may be stored within at least one storage unit of the evaluation device. The evaluation device may be adapted to determine a straight line extending from the selected reflection feature to the real world feature from which it originates. Thus, the straight line may comprise possible object features corresponding to the selected reflection feature. The straight line and the baseline span an epipolar plane. As the reference pattern is determined at a different relative constellation from the reflection pattern, the corresponding possible object features may be imaged on a straight line, called epipolar line, in the reference pattern. The epipolar line may be the intersection of the epipolar plane and the reference pattern. Thus, a feature of the reference pattern corresponding to the selected feature of the reflection pattern lies on the epipolar line.

Depending on the distance to the object, the reference feature corresponding to the image position of the reflection feature may be displaced within the reference pattern compared to the image position in the reflection pattern. The reference pattern may comprise at least one displacement region in which the reference feature corresponding to the selected reflection feature may be imaged. The displacement region may comprise only one reference feature. The displacement region may extend along the epipolar line. The evaluation device may be adapted to determine the reference feature along the epipolar line. The evaluation device may be adapted to determine the longitudinal coordinate z for the reflection feature and an error interval $\pm \varepsilon$ from the quotient signal Q to determine a displacement region along the epipolar line corresponding to $z \pm \varepsilon$. The evaluation device may be adapted to match the selected reflection feature with at

least one reference feature within the displacement region. As used herein, the term “matching” refers to determining and/or evaluating the corresponding reference and reflection features. The evaluation device may be adapted to match the selected feature of the reflection pattern with the reference feature within the displacement region by using at least one evaluation algorithm considering the determined longitudinal coordinate z . The evaluation algorithm may be a linear scaling algorithm. Preferably, the detector may be adapted to pre-classify the selected reflection feature using the quotient signal Q such that an unambiguous assignment to one reference feature is possible. In particular, illumination features of the illumination pattern may be arranged such that corresponding reference features of the reference pattern may have a relative distance to each other as large as possible on the epipolar line. The illumination features of the illumination pattern may be arranged such that only few reference features are positioned on the epipolar line. For example, the illumination pattern may comprise at least one hexagonal pattern. Preferably, the illumination pattern may comprise at least one hexagonal pattern, wherein the pattern is rotated relative to the baseline. Preferably, the illumination pattern may comprise at least one displaced hexagonal pattern, wherein individual points of the hexagonal pattern are displaced by a random distance from the regular position, for example orthogonal to the epipolar line of the point. The displacement of the individual points may be smaller than half of the distance between two parallel epipolar lines, preferably smaller than one fourth of the distance between two parallel epipolar lines. The displacement of the individual points may be as such that two points are not displaced above each other.

The evaluation device may be adapted to determine a displacement of the reference feature and the reflection feature. The evaluation device may be adapted to determine the displacement of the matched reference feature and the selected reflection feature. As used herein, the term “displacement” refers to the difference between an image position in the reference image to an image position in the reflection image. The evaluation device may be adapted to determine a longitudinal information of the matched feature using a predetermined relationship between a longitudinal coordinate and the displacement. As used herein, the term “longitudinal information” refers to information relating to the longitudinal coordinate z_{triang} . For example, the longitudinal information may be a distance value. The evaluation device may be adapted to determine the pre-determined relationship by using triangulation methods. In case the position of the selected reflection feature in the reflection pattern and the position of the matched reference feature and/or the relative displacement of the selected reflection feature and the matched reference feature are known, the longitudinal coordinate of the corresponding object feature may be determined by triangulation. Thus, the evaluation device may be adapted to select, for example subsequent and/or column by column, a reflection feature and to determine for each potential position of the reference feature the corresponding distance value using triangulation. The displacement and the corresponding distance value may be stored in at least one storage device of the evaluation device. The evaluation device may, as an example, comprise at least one data processing device, such as at least one processor, at least one DSP, at least one FPGA and/or at least one ASIC. Further, for storing the at least one predetermined or determinable relationship between the longitudinal coordinate z and the displacement, the at least one

data storage device may be provided, such as for providing one or more look-up tables for storing the predetermined relationship.

5 The detector may comprise at least one FiP sensor adapted for generating the so called FiP effect as described in WO 2015/024871 or WO2016/120392. For example, at least one optical sensors of the matrix of optical sensors may be adapted to generate a so called FiP signal. For example, each of the optical sensors of the matrix may be adapted to generate the at least one FiP signal. For example, the matrix of optical sensors may be a pixelated FiP-sensor. Additionally or alternatively, the FiP signal may be determined, such as extracted and/or simulated, from
10 the sensor signals of the matrix and the quotient as outlined above may be determined from the sensor signals. As outlined e.g. in WO 2015/024871 or WO2016/120392, the FiP signal can be used to determine depth information over a wide distance range. The FiP sensor may be adapted to exhibit a positive and/or a negative FiP effect. According to the FiP-effect, the longitudinal sensor signal, given the same total power, may exhibit at least one pronounced maximum for one or a plurality of focusings and/or for one or a plurality of specific sizes of the light spot on the sensor region or within the sensor region. For purposes of comparison, an observation of a maximum of the longitudinal sensor signal in a condition in which the corresponding material is impinged by a light beam with the smallest possible cross-section, such as when the material may be located at or near a focal point as affected by an optical lens, may be denominated as a "positive FiP-effect". The negative FiP effect describes an observation of a minimum of the longitudinal sensor signal under a condition in which the corresponding material is impinged by a light beam with the smallest available beam cross-section, in particular, when the material may be located at or near a focal point as effected by an optical lens. The negative FiP effect may be used to tune small image effects at high distances. Image changes such as position, size, shape, sharpness, etc. may vanish at high distances while the negative FiP effect increases. Furthermore, no luminance dependence may be introduced since both cells are at the same longitudinal position and thus receive identical photon density.

As outlined above, the detector may further comprise one or more additional elements such as
30 one or more additional optical elements. Further, the detector may fully or partially be integrated into at least one housing. The detector specifically may comprise at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensor. The transfer device may comprise one or more of: at least one lens, preferably at least one focus-tunable lens; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at
35 least one multi-lens system. Therein, generally, the term "transfer device" may generally refer to one or more optical elements which are adapted to modify the light beam, such as by modifying one or more of a beam parameter of the light beam, a width of the light beam or a direction of the light beam. The transfer device may be adapted to guide the light beam onto the optical
40 sensors. The transfer device specifically may comprise one or more of: at least one lens, for example at least one lens selected from the group consisting of , preferably at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection

element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

5 In a further aspect of the present invention, a detector system for determining a position of at least one object is disclosed. The detector system comprises at least one detector according to the present invention, such as according to one or more of the embodiments disclosed above or according to one or more of the embodiments disclosed in further detail below. The detector system further comprises at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object. Further details regarding the beacon device will be given below, including potential embodiments thereof. Thus, the at least one beacon device may be or may comprise at least one active beacon device, comprising one or more illumination sources such as one or more light sources like lasers, LEDs, light bulbs or the like. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Alternatively, as outlined above, the infrared spectral range may be used, such as in the range of 780 nm to 3.0 μm . The light emitted by the one or more beacon devices may be non-modulated or may be modulated, as outlined above, in order to distinguish two or more light beams. Additionally or alternatively, the at least one beacon device may be adapted to reflect one or more light beams towards the detector, such as by comprising one or more reflective elements. Further, the at least one beacon device may be or may comprise one or more scattering elements adapted for scattering a light beam. Therein, elastic or inelastic scattering may be used. In case the at least one beacon device is adapted to reflect and/or scatter a primary light beam towards the detector, the beacon device may be adapted to leave the spectral properties of the light beam unaffected or, alternatively, may be adapted to change the spectral properties of the light beam, such as by modifying a wavelength of the light beam.

30 In a further aspect of the present invention, a human-machine interface for exchanging at least one item of information between a user and a machine is disclosed. The human-machine interface comprises at least one detector system according to the embodiments disclosed above and/or according to one or more of the embodiments disclosed in further detail below. Therein, the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user or held by the user. The human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to assign to the position at least one item of information.

35 In a further aspect of the present invention, an entertainment device for carrying out at least one entertainment function is disclosed. The entertainment device comprises at least one human-machine interface according to the embodiment disclosed above and/or according to one or more of the embodiments disclosed in further detail below. The entertainment device is configured to enable at least one item of information to be input by a player by means of the human-machine interface. The entertainment device is further configured to vary the entertainment function in accordance with the information.

In a further aspect of the present invention, a tracking system for tracking a position of at least one movable object is disclosed. The tracking system comprises at least one detector system according to one or more of the embodiments referring to a detector system as disclosed above and/or as disclosed in further detail below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time.

In a further aspect of the present invention, a camera for imaging at least one object is disclosed. The camera comprises at least one detector according to any one of the embodiments referring to a detector as disclosed above or as disclosed in further detail below.

In a further aspect of the present invention, a scanning system for determining a depth profile of a scenery, which may also imply determining at least one position of at least one object, is provided. The scanning system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The scanning system further comprises at least one illumination source adapted to scan the scenery with at least one light beam, which may also be referred to as an illumination light beam or scanning light beam. As used herein, the term "scenery" generally refers to a two-dimensional or three-dimensional range which is visible by the detector, such that at least one geometric or spatial property of the two-dimensional or three-dimensional range may be evaluated with the detector. As further used herein, the term "scan" generally refers to a consecutive measurement in different regions. Thus, the scanning specifically may imply at least one first measurement with the illumination light beam being oriented or directed in a first fashion, and at least one second measurement with the illumination light beam being oriented or directed in a second fashion which is different from the first fashion. The scanning may be a continuous scanning or a stepwise scanning. Thus, in a continuous or stepwise fashion, the illumination light beam may be directed into different regions of the scenery, and the detector may be detected to generate at least one item of information, such as at least one longitudinal coordinate, for each region. As an example, for scanning an object, one or more illumination light beams may, continuously or in a stepwise fashion, create light spots on the surface of the object, wherein longitudinal coordinates are generated for the light spots. Alternatively, however, a light pattern may be used for scanning. The scanning may be a point scanning or a line scanning or even a scanning with more complex light patterns. The illumination source of the scanning system may be distinct from the optional illumination source of the detector. Alternatively, however, the illumination source of the scanning system may also be fully or partially identical with or integrated into the at least one optional illumination source of the detector.

Thus, the scanning system may comprise at least one illumination source which is adapted to emit the at least one light beam being configured for the illumination of the at least one dot located at the at least one surface of the at least one object. As used herein, the term "dot" refers to an area, specifically a small area, on a part of the surface of the object which may be selected, for example by a user of the scanning system, to be illuminated by the illumination source.

Preferably, the dot may exhibit a size which may, on one hand, be as small as possible in order to allow the scanning system to determine a value for the distance between the illumination source comprised by the scanning system and the part of the surface of the object on which the dot may be located as exactly as possible and which, on the other hand, may be as large as possible in order to allow the user of the scanning system or the scanning system itself, in particular by an automatic procedure, to detect a presence of the dot on the related part of the surface of the object.

For this purpose, the illumination source may comprise an artificial illumination source, in particular at least one laser source and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Additionally or alternatively, light in the infrared spectral range may be used, such as in the range of 780 nm to 3.0 μm . On account of their generally defined beam profiles and other properties of handleability, the use of at least one laser source as the illumination source is particularly preferred. Herein, the use of a single laser source may be preferred, in particular in a case in which it may be important to provide a compact scanning system that might be easily storable and transportable by the user. The illumination source may thus, preferably be a constituent part of the detector and may, therefore, in particular be integrated into the detector, such as into the housing of the detector. In a preferred embodiment, particularly the housing of the scanning system may comprise at least one display configured for providing distance-related information to the user, such as in an easy-to-read manner. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least one button which may be configured for operating at least one function related to the scanning system, such as for setting one or more operation modes. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least one fastening unit which may be configured for fastening the scanning system to a further surface, such as a rubber foot, a base plate or a wall holder, such as a base plate or holder comprising a magnetic material, in particular for increasing the accuracy of the distance measurement and/or the handleability of the scanning system by the user.

Particularly, the illumination source of the scanning system may, thus, emit a single laser beam which may be configured for the illumination of a single dot located at the surface of the object. By using at least one of the detectors according to the present invention at least one item of information about the distance between the at least one dot and the scanning system may, thus, be generated. Hereby, preferably, the distance between the illumination system as comprised by the scanning system and the single dot as generated by the illumination source may be determined, such as by employing the evaluation device as comprised by the at least one detector. However, the scanning system may, further, comprise an additional evaluation system which may, particularly, be adapted for this purpose. Alternatively or in addition, a size of the scanning system, in particular of the housing of the scanning system, may be taken into account and, thus, the distance between a specific point on the housing of the scanning system, such as a front edge or a back edge of the housing, and the single dot may, alternatively, be determined.

Alternatively, the illumination source of the scanning system may emit two or more individual laser beams which may be configured for providing a respective angle, such as a right angle, between the directions of an emission of the beams, whereby two respective dots located at the surface of the same object or at two different surfaces at two separate objects may be illuminated. However, other values for the respective angle between the two individual laser beams may also be feasible. This feature may, in particular, be employed for indirect measuring functions, such as for deriving an indirect distance which may not be directly accessible, such as due to a presence of one or more obstacles between the scanning system and the dot or which may otherwise be hard to reach. By way of example, it may, thus, be feasible to determine a value for a height of an object by measuring two individual distances and deriving the height by using the Pythagoras formula. In particular for being able to keep a predefined level with respect to the object, the scanning system may, further, comprise at least one leveling unit, in particular an integrated bubble vial, which may be used for keeping the predefined level by the user.

As a further alternative, the illumination source of the scanning system may emit a plurality of individual laser beams, such as an array of laser beams which may exhibit a respective pitch, in particular a regular pitch, with respect to each other and which may be arranged in a manner in order to generate an array of dots located on the at least one surface of the at least one object. For this purpose, specially adapted optical elements, such as beam-splitting devices and mirrors, may be provided which may allow a generation of the described array of the laser beams. In particular, the illumination source may be directed to scan an area or a volume by using one or more movable mirrors to redirect the light beam in a periodic or non-periodic fashion.

Thus, the scanning system may provide a static arrangement of the one or more dots placed on the one or more surfaces of the one or more objects. Alternatively, the illumination source of the scanning system, in particular the one or more laser beams, such as the above described array of the laser beams, may be configured for providing one or more light beams which may exhibit a varying intensity over time and/or which may be subject to an alternating direction of emission in a passage of time, in particular by moving one or more mirrors, such as the micro-mirrors comprised within the mentioned array of micro-mirrors. As a result, the illumination source may be configured for scanning a part of the at least one surface of the at least one object as an image by using one or more light beams with alternating features as generated by the at least one illumination source of the scanning device. In particular, the scanning system may, thus, use at least one row scan and/or line scan, such as to scan the one or more surfaces of the one or more objects sequentially or simultaneously. As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step. As non-limiting examples, the scanning system may be used in industrial safety curtain applications. As non-limiting examples, the scanning system may be used to perform sweeping, vacuuming, mopping, or waxing functions, or yard or garden care functions such as

mowing or raking. As non-limiting examples, the scanning system may employ an LED illumination source with collimated optics and may be adapted to shift the frequency of the illumination source to a different frequency to obtain more accurate results and/or employ a filter to attenuate certain frequencies while transmitting others. As non-limiting examples, the scanning system and/or the illumination source may be rotated as a whole or rotating only a particular optics package such as a mirror, beam splitter or the like, using a dedicated motor as such that in operation, the scanning system may have a full 360 degree view or even be moved and or rotated out of plane to further increase the scanned area. Further, the illumination source may be actively aimed in a predetermined direction. Further, to allow the rotation of wired electrical systems, slip rings, optical data transmission, or inductive couplings may be employed.

As a non-limiting example, the scanning system may be attached to a tripod and point towards an object or region with a several corners and surfaces. One or more flexibly movable laser sources may be attached to the scanning system. The one or more laser sources may be moved as such that they illuminate points of interest. The position of the illuminated points with respect to the scanning system may be measured when pressing a designated button on the scanning system and the position information is transmitted via a wireless interface to a mobile phone. The position information may be stored in a mobile phone application. The laser sources may be moved to illuminate further points of interest the position of which are measured and transmitted to the mobile phone application. The mobile phone application may transform the set of points into a 3d model by connecting adjacent points with planar surfaces. The 3d model may be stored and processed further. The distances and/or angles between the measured points or surfaces may be displayed directly on a display attached to a scanning system or on the mobile phone to which the position information is transmitted.

As a non-limiting example, a scanning system may comprise two or more flexible movable laser sources to project points and further one movable laser source projecting a line. The line may be used to arrange the two or more laser spots along a line and the display of the scanning device may display the distance between the two or more laser spots that may be arranged along the line, such as at equal distance. In the case of two laser spots, a single laser source may be used whereas the distance of the projected points is modified using one or more beam-splitters or prisms, where a beam-splitter or prism can be moved as such that the projected laser spots move apart or closer together. Further, the scanning system may be adapted to project further patterns such as a right angle, a circle, a square, a triangle, or the like, along which a measurement can be done by projecting laser spots and measuring their position.

As a non-limiting example, the scanning system may be adapted as a line scanning device. In particular, the scanning device may comprise at least one sensor line or row. Triangulation systems require a sufficient baseline such that in the near field no detection may be possible. Near field detection may be possible if the laser spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. These near field and far field problems can be overcome by using the detector according to the present invention. In particular, the detector may comprise a CMOS line of

optical sensors. The scanning system may be adapted to detect a plurality of light beams propagating from the object to the detector on the CMOS line. The light beams may be generated at different positions on the object or by movement of the illumination source. The scanning system may be adapted to determine at least one longitudinal coordinate for each of the light points by determining the quotient signal Q as described above and in more detail below.

As a non-limiting example, the scanning system may be adapted to support the work with tools, such as wood or metal processing tools, such as a saw, a driller, or the like. Thus, the scanning system may be adapted to measure the distance in two opposite directions and display the two measured distances or the sum of the distances in a display. Further, the scanning system may be adapted to measure the distance to the edge of a surface as such that when the scanning system is placed on the surface, a laser point is moved automatically away from the scanning system along the surface, until the distance measurement shows a sudden change due to a corner or the edge of a surface. This makes it possible to measure the distance of the end of a wood plank while the scanning device is placed on the plank but remote from its end. Further, the scanning system may measure the distance of the end of a plank in one direction and project a line or circle or point in a designated distance in the opposite direction. The scanning system may be adapted to project the line or circle or point in a distance depending on the distance measured in the opposite direction such as depending on a predetermined sum distance. This allows working with a tool such as a saw or driller at the projected position while placing the scanning system in a safe distance from the tool and simultaneously perform a process using the tool in a predetermined distance to the edge of the plank. Further, the scanning system may be adapted to project points or lines or the like in two opposite directions in a predetermined distance. When the sum of the distances is changed, only one of the projected distances changes.

As a non-limiting example, the scanning system may be adapted to be placed onto a surface, such as a surface on which a task is performed, such as cutting, sawing, drilling, or the like, and to project a line onto the surface in a predetermined distance that can be adjusted such as with buttons on the scanning device.

As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step.

The optional transfer device can, as explained above, be designed to feed light propagating from the object to the detector to the optical sensor, preferably successively. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the optical sensor. The optional

transfer device can also be wholly or partly a constituent part of at least one optional illumination source, for example by the illumination source being designed to provide a light beam having defined optical properties, for example having a defined or precisely known beam profile, for example at least one Gaussian beam, in particular at least one laser beam having a known beam profile.

For potential embodiments of the optional illumination source, reference may be made to WO 2012/110924 A1. Still, other embodiments are feasible. Light emerging from the object can originate in the object itself, but can also optionally have a different origin and propagate from this origin to the object and subsequently toward the transversal and/or longitudinal optical sensor. The latter case can be effected for example by at least one illumination source being used. This illumination source can for example be or comprise an ambient illumination source and/or may be or may comprise an artificial illumination source. By way of example, the detector itself can comprise at least one illumination source, for example at least one laser and/or at least one incandescent lamp and/or at least one semiconductor illumination source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. On account of their generally defined beam profiles and other properties of handleability, the use of one or a plurality of lasers as illumination source or as part thereof, is particularly preferred. The illumination source itself can be a constituent part of the detector or else be formed independently of the detector. The illumination source can be integrated in particular into the detector, for example a housing of the detector. Alternatively or additionally, at least one illumination source can also be integrated into the at least one beacon device or into one or more of the beacon devices and/or into the object or connected or spatially coupled to the object.

The light emerging from the one or more optional beacon devices can accordingly, alternatively or additionally from the option that said light originates in the respective beacon device itself, emerge from the illumination source and/or be excited by the illumination source. By way of example, the electromagnetic light emerging from the beacon device can be emitted by the beacon device itself and/or be reflected by the beacon device and/or be scattered by the beacon device before it is fed to the detector. In this case, emission and/or scattering of the electromagnetic radiation can be effected without spectral influencing of the electromagnetic radiation or with such influencing. Thus, by way of example, a wavelength shift can also occur during scattering, for example according to Stokes or Raman. Furthermore, emission of light can be excited, for example, by a primary illumination source, for example by the object or a partial region of the object being excited to generate luminescence, in particular phosphorescence and/or fluorescence. Other emission processes are also possible, in principle. If a reflection occurs, then the object can have for example at least one reflective region, in particular at least one reflective surface. Said reflective surface can be a part of the object itself, but can also be for example a reflector which is connected or spatially coupled to the object, for example a reflector plaque connected to the object. If at least one reflector is used, then it can in turn also be regarded as part of the detector which is connected to the object, for example, independently of other constituent parts of the detector.

The beacon devices and/or the at least one optional illumination source generally may emit light in at least one of: the ultraviolet spectral range, preferably in the range of 200 nm to 380 nm; the visible spectral range (380 nm to 780 nm); the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers. For thermal imaging applications the target may emit light in the far infrared spectral range, preferably in the range of 3.0 micrometers to 20 micrometers. Most preferably, the at least one illumination source is adapted to emit light in the infrared spectral range. Other options, however, are feasible.

The feeding of the light beam to the sensor element can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is produced on the optional sensor area of the sensor element. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects can be detected. Preferably, the optional transfer device is designed in such a way that the light spot, for example in the case of an object arranged within a visual range of the detector, is arranged completely on a sensor region and/or on a sensor area of the optical sensor. By way of example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

In a further aspect, the present invention discloses an inertial measurement unit for use in an electronic device. The electronic device may be a mobile electronic device. The electronic device may be a camera. The electronic device may be a mobile phone. The inertial measurement unit is adapted to receive data determined by at least one inertial measurement unit comprising at least one detector according to the present invention, such as according to one or more of the embodiments referring to a detector as disclosed above or as disclosed in further detail below. As used herein, the term "data determined by the at least one detector" refers to at least one information on the at least one longitudinal coordinate z . The inertial measurement unit further is adapted to receive data determined by at least one further sensor selected from the group consisting of: a wheel speed sensor, a turn rate sensor, an inclination sensor, an orientation sensor, a motion sensor, a magneto hydro dynamic sensor, a force sensor, an angular sensor, an angular rate sensor, a magnetic field sensor, a magnetometer, an accelerometer; a gyroscope. As used herein, the term "data determined by the at least one further sensor" refers to at least one information selected from the group consisting of: angle information; speed information; information on turn rate; information on inclination. The inertial measurement unit is adapted to determine by evaluating the data from the detector and the at least one further sensor at least one property of the electronic device selected from the group consisting of: position in space, relative or absolute motion in space, rotation, acceleration, orientation, angle position, inclination, turn rate, speed. The inertial measurement unit may comprise at least one processor. The processor may be adapted to evaluate data recorded by the further sensor. In particular, the processor may be adapted to determine and/or calculate one or more of spatial position, spatial orientation, movement and velocity. The inertial measurement unit may comprise a plurality of further sensors. The inertial measurement unit may be adapted to fuse information determined from at least two of the further sensors. The inertial measurement unit may be adapted to fuse information of at least two further sensors by using at least one Kalman filter. As outlined

above, the detector may be adapted to provide an absolute measurement of the longitudinal coordinate z . The processor, e.g. the evaluation device as described above, may be adapted to fuse the information of the at least two further sensors considering the longitudinal coordinate z . The various sensor signals may be used within a Kalman filter or a linear quadratic estimated to take into account that each sensor signal is subject to measurement errors and inaccuracies. Fusion of these sensor signals within a Kalman filter may yield an improved estimate such as for the measurement of the longitudinal coordinate.

In a further aspect, the present invention discloses a method for determining a position of at least one object by using a detector, such as a detector according to the present invention, such as according to one or more of the embodiments referring to a detector as disclosed above or as disclosed in further detail below. Still, other types of detectors may be used.

The method comprises the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed. Further, one, more than one or even all of the method steps may be performed repeatedly.

The method steps are as follows:

- illuminating at least one sensor element of the detector with at least one light beam propagating from the object to the detector, the detector having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor generates at least one sensor signal in response to the illumination;
- evaluating the sensor signals, by
 - a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
 - b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and
 - d) determining at least one longitudinal coordinate z of the object by evaluating the combined signal.

Specifically, the evaluation of the first and second sensor signal may comprise deriving a combined signal Q by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa. Further, the determination of the longitudinal coordinate may comprise evaluating the combined signal Q . The evaluation of the combined signal specifically may comprise using at least one predetermined relationship between the combined signal Q and the longitudinal coordinate, in order to determine the longitudinal coordinate.

For details, options and definitions, reference may be made to the detector as discussed above. Thus, specifically, as outlined above, the method may comprise using the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below.

5

In a further aspect of the present invention, use of the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below, is proposed, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a tracking application; a photography application; a logistics application; a machine vision application; a robotics application; a quality control application; a manufacturing application;.

10

The object generally may be a living or non-living object. The detector or the detector system even may comprise the at least one object, the object thereby forming part of the detector system. Preferably, however, the object may move independently from the detector, in at least one spatial dimension. The object generally may be an arbitrary object. In one embodiment, the object may be a rigid object. Other embodiments are feasible, such as embodiments in which the object is a non-rigid object or an object which may change its shape.

15

20

As will be outlined in further detail below, the present invention may specifically be used for tracking positions and/or motions of a person, such as for the purpose of controlling machines, gaming or simulation of sports. In this or other embodiments, specifically, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat; an article of clothing; a hat; a shoe.

25

Thus, generally, the devices according to the present invention, such as the detector, may be applied in various fields of uses. Specifically, the detector may be applied for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a human-machine interface application; a tracking application; a photography application; a mapping application for generating maps of at least one space, such as at least one space selected from the group of a room, a building and a street; a mobile application; a webcam; an audio device; a dolby surround audio system; a computer peripheral device; a gaming application; a camera or video application; a security application; a surveillance application; an automotive application; a transport application; a medical application; a sports' application; a machine vision application; a vehicle application; an airplane application; a ship application; a spacecraft application; a building application; a construction application; a cartography application; a manufacturing application. Additionally or alternatively, applications in local and/or global positioning systems may be named, especially land-mark-based positioning and/or navigation, specifically for use in cars or other vehicles (such as trains, motorcycles, bicycles, trucks for cargo transportation), robots or for use by pedestrians. Further, indoor positioning systems may be named as potential applications, such as for house-

30

35

40

hold applications and/or for robots used in manufacturing, logistics, surveillance, or maintenance technology.

The devices according to the present invention may be used in mobile phones, tablet computers, laptops, smart panels or other stationary or mobile or wearable computer or communication applications. Thus, the devices according to the present invention may be combined with at least one active light source, such as a light source emitting light in the visible range or infrared spectral range, in order to enhance performance. Thus, as an example, the devices according to the present invention may be used as cameras and/or sensors, such as in combination with mobile software for scanning and/or detecting environment, objects and living beings. The devices according to the present invention may even be combined with 2D cameras, such as conventional cameras, in order to increase imaging effects. The devices according to the present invention may further be used for surveillance and/or for recording purposes or as input devices to control mobile devices, especially in combination with voice and/or gesture recognition. Thus, specifically, the devices according to the present invention acting as human-machine interfaces, also referred to as input devices, may be used in mobile applications, such as for controlling other electronic devices or components via the mobile device, such as the mobile phone. As an example, the mobile application including at least one device according to the present invention may be used for controlling a television set, a game console, a music player or music device or other entertainment devices.

Further, the devices according to the present invention may be used in webcams or other peripheral devices for computing applications. Thus, as an example, the devices according to the present invention may be used in combination with software for imaging, recording, surveillance, scanning or motion detection. As outlined in the context of the human-machine interface and/or the entertainment device, the devices according to the present invention are particularly useful for giving commands by facial expressions and/or body expressions. The devices according to the present invention can be combined with other input generating devices like e.g. mouse, keyboard, touchpad, microphone etc. Further, the devices according to the present invention may be used in applications for gaming, such as by using a webcam. Further, the devices according to the present invention may be used in virtual training applications and/or video conferences. Further, devices according to the present invention may be used to recognize or track hands, arms, or objects used in a virtual or augmented reality application, especially when wearing head-mounted displays.

Further, the devices according to the present invention may be used in mobile audio devices, television devices and gaming devices, as partially explained above. Specifically, the devices according to the present invention may be used as controls or control devices for electronic devices, entertainment devices or the like. Further, the devices according to the present invention may be used for eye detection or eye tracking, such as in 2D- and 3D-display techniques, especially with transparent displays for augmented reality applications and/or for recognizing whether a display is being looked at and/or from which perspective a display is being looked at. Further, devices according to the present invention may be used to explore a room, boundaries,

obstacles, in connection with a virtual or augmented reality application, especially when wearing a head-mounted display.

Further, the devices according to the present invention may be used in or as digital cameras such as DSC cameras and/or in or as reflex cameras such as SLR cameras. For these applications, reference may be made to the use of the devices according to the present invention in mobile applications such as mobile phones, as disclosed above.

Further, the devices according to the present invention may be used for security or surveillance applications. Thus, as an example, at least one device according to the present invention can be combined with one or more digital and/or analogue electronics that will give a signal if an object is within or outside a predetermined area (e.g. for surveillance applications in banks or museums). Specifically, the devices according to the present invention may be used for optical encryption. Detection by using at least one device according to the present invention can be combined with other detection devices to complement wavelengths, such as with IR, x-ray, UV-VIS, radar or ultrasound detectors. The devices according to the present invention may further be combined with an active infrared light source to allow detection in low light surroundings. The devices according to the present invention are generally advantageous as compared to active detector systems, specifically since the devices according to the present invention avoid actively sending signals which may be detected by third parties, as is the case e.g. in radar applications, ultrasound applications, LIDAR or similar active detector devices. Thus, generally, the devices according to the present invention may be used for an unrecognized and undetectable tracking of moving objects. Additionally, the devices according to the present invention generally are less prone to manipulations and irritations as compared to conventional devices.

Further, given the ease and accuracy of 3D detection by using the devices according to the present invention, the devices according to the present invention generally may be used for facial, body and person recognition and identification. Therein, the devices according to the present invention may be combined with other detection means for identification or personalization purposes such as passwords, finger prints, iris detection, voice recognition or other means. Thus, generally, the devices according to the present invention may be used in security devices and other personalized applications.

Further, the devices according to the present invention may be used as 3D barcode readers for product identification.

In addition to the security and surveillance applications mentioned above, the devices according to the present invention generally can be used for surveillance and monitoring of spaces and areas. Thus, the devices according to the present invention may be used for surveying and monitoring spaces and areas and, as an example, for triggering or executing alarms in case prohibited areas are violated. Thus, generally, the devices according to the present invention may be used for surveillance purposes in building surveillance or museums, optionally in combination with other types of sensors, such as in combination with motion or heat sensors, in

combination with image intensifiers or image enhancement devices and/or photomultipliers. Further, the devices according to the present invention may be used in public spaces or crowded spaces to detect potentially hazardous activities such as commitment of crimes such as theft in a parking lot or unattended objects such as unattended baggage in an airport.

Further, the devices according to the present invention may advantageously be applied in camera applications such as video and camcorder applications. Thus, the devices according to the present invention may be used for motion capture and 3D-movie recording. Therein, the devices according to the present invention generally provide a large number of advantages over conventional optical devices. Thus, the devices according to the present invention generally require a lower complexity with regard to optical components. Thus, as an example, the number of lenses may be reduced as compared to conventional optical devices, such as by providing the devices according to the present invention having one lens only. Due to the reduced complexity, very compact devices are possible, such as for mobile use. Conventional optical systems having two or more lenses with high quality generally are voluminous, such as due to the general need for voluminous beam-splitters. Further, the devices according to the present invention generally may be used for focus/autofocus devices, such as autofocus cameras. Further, the devices according to the present invention may also be used in optical microscopy, especially in confocal microscopy.

Further, the devices according to the present invention generally are applicable in the technical field of automotive technology and transport technology. Thus, as an example, the devices according to the present invention may be used as distance and surveillance sensors, such as for adaptive cruise control, emergency brake assist, lane departure warning, surround view, blind spot detection, traffic sign detection, traffic sign recognition, lane recognition, rear cross traffic alert, light source recognition for adapting the head light intensity and range depending on approaching traffic or vehicles driving ahead, adaptive frontlighting systems, automatic control of high beam head lights, adaptive cut-off lights in front light systems, glare-free high beam front lighting systems, marking animals, obstacles, or the like by headlight illumination, rear cross traffic alert, and other driver assistance systems such as advanced driver assistance systems, or other automotive and traffic applications. Further, devices according to the present invention may be used in driver assistance systems anticipating maneuvers of the driver beforehand for collision avoidance or the like. Further, the devices according to the present invention can also be used for velocity and/or acceleration measurements, such as by analyzing a first and second time-derivative of position information gained by using the detector according to the present invention. This feature generally may be applicable in automotive technology, transportation technology or general traffic technology. Applications in other fields of technology are feasible. A specific application in an indoor positioning system may be the detection of positioning of passengers in transportation, more specifically to electronically control the use of safety systems such as airbags. The use of an airbag may be prevented in case the passenger is located as such, that the use of an airbag will cause a severe injury. Further, in vehicles such as cars, trains, planes or the like, especially in autonomous vehicles, devices according to the present

invention may be used to determine whether a driver pays attention to the traffic or is distracted, or asleep, or tired, or incapable of driving such as due to the consumption of alcohol or the like.

5 In these or other applications, generally, the devices according to the present invention may be used as standalone devices or in combination with other sensor devices, such as in combination with radar and/or ultrasonic devices. Specifically, the devices according to the present invention may be used for autonomous driving and safety issues. Further, in these applications, the devices according to the present invention may be used in combination with infrared sensors, radar sensors, which are sonic sensors, two-dimensional cameras or other types of sensors. In these applications, the generally passive nature of the devices according to the present invention is advantageous. Thus, since the devices according to the present invention generally do not require emitting signals, the risk of interference of active sensor signals with other signal sources may be avoided. The devices according to the present invention specifically may be used in combination with recognition software, such as standard image recognition software. 10 Thus, signals and data as provided by the devices according to the present invention typically are readily processable and, therefore, generally require lower calculation power than established 3D measurement systems. Given the low space demand, the devices according to the present invention such as cameras may be placed at virtually any place in a vehicle, such as on or behind a window screen, on a front hood, on bumpers, on lights, on mirrors or other places and the like. Various detectors according to the present invention such as one or more detectors based on the effect disclosed within the present invention can be combined, such as in order to allow autonomously driving vehicles or in order to increase the performance of active safety concepts. Thus, various devices according to the present invention may be combined with one or more other devices according to the present invention and/or conventional sensors, 20 such as in the windows like rear window, side window or front window, on the bumpers or on the lights.

A combination of at least one device according to the present invention such as at least one detector according to the present invention with one or more rain detection sensors is also possible. This is due to the fact that the devices according to the present invention generally are advantageous over conventional sensor techniques such as radar, specifically during heavy rain. A combination of at least one device according to the present invention with at least one conventional sensing technique such as radar may allow for a software to pick the right combination of signals according to the weather conditions. 30

Further, the devices according to the present invention generally may be used as break assist and/or parking assist and/or for speed measurements. Speed measurements can be integrated in the vehicle or may be used outside the vehicle, such as in order to measure the speed of other cars in traffic control. Further, the devices according to the present invention may be used 40 for detecting free parking spaces in parking lots.

Further, the devices according to the present invention may be used in the fields of medical systems and sports. Thus, in the field of medical technology, surgery robotics, e.g. for use in endo-

scopes, may be named, since, as outlined above, the devices according to the present invention may require a low volume only and may be integrated into other devices. Specifically, the devices according to the present invention having one lens, at most, may be used for capturing 3D information in medical devices such as in endoscopes. Further, the devices according to the present invention may be combined with an appropriate monitoring software, in order to enable tracking and analysis of movements. This may allow an instant overlay of the position of a medical device, such as an endoscope or a scalpel, with results from medical imaging, such as obtained from magnetic resonance imaging, x-ray imaging, or ultrasound imaging. These applications are specifically valuable e.g. in medical treatments where precise location information is important such as in brain surgery and long-distance diagnosis and tele-medicine. Further, the devices according to the present invention may be used in 3D-body scanning. Body scanning may be applied in a medical context, such as in dental surgery, plastic surgery, bariatric surgery, or cosmetic plastic surgery, or it may be applied in the context of medical diagnosis such as in the diagnosis of myofascial pain syndrome, cancer, body dysmorphic disorder, or further diseases. Body scanning may further be applied in the field of sports to assess ergonomic use or fit of sports equipment.

Body scanning may further be used in the context of clothing, such as to determine a suitable size and fitting of clothes. This technology may be used in the context of tailor-made clothes or in the context of ordering clothes or shoes from the internet or at a self-service shopping device such as a micro kiosk device or customer concierge device. Body scanning in the context of clothing is especially important for scanning fully dressed customers.

Further, the devices according to the present invention may be used in the context of people counting systems, such as to count the number of people in an elevator, a train, a bus, a car, or a plane, or to count the number of people passing a hallway, a door, an aisle, a retail store, a stadium, an entertainment venue, a museum, a library, a public location, a cinema, a theater, or the like. Further, the 3D-function in the people counting system may be used to obtain or estimate further information about the people that are counted such as height, weight, age, physical fitness, or the like. This information may be used for business intelligence metrics, and/or for further optimizing the locality where people may be counted to make it more attractive or safe. In a retail environment, the devices according to the present invention in the context of people counting may be used to recognize returning customers or cross shoppers, to assess shopping behavior, to assess the percentage of visitors that make purchases, to optimize staff shifts, or to monitor the costs of a shopping mall per visitor. Further, people counting systems may be used for anthropometric surveys. Further, the devices according to the present invention may be used in public transportation systems for automatically charging passengers depending on the length of transport. Further, the devices according to the present invention may be used in playgrounds for children, to recognize injured children or children engaged in dangerous activities, to allow additional interaction with playground toys, to ensure safe use of playground toys or the like.

Further, the devices according to the present invention may be used in construction tools, such as a range meter that determines the distance to an object or to a wall, to assess whether a

surface is planar, to align objects or place objects in an ordered manner, or in inspection cameras for use in construction environments or the like.

5 Further, the devices according to the present invention may be applied in the field of sports and exercising, such as for training, remote instructions or competition purposes. Specifically, the devices according to the present invention may be applied in the fields of dancing, aerobic, football, soccer, basketball, baseball, cricket, hockey, track and field, swimming, polo, handball, volleyball, rugby, sumo, judo, fencing, boxing, golf, car racing, laser tag, battlefield simulation
10 etc. The devices according to the present invention can be used to detect the position of a ball, a bat, a sword, motions, etc., both in sports and in games, such as to monitor the game, support the referee or for judgment, specifically automatic judgment, of specific situations in sports, such as for judging whether a point or a goal actually was made.

15 Further, the devices according to the present invention may be used in the field of auto racing or car driver training or car safety training or the like to determine the position of a car or the track of a car, or the deviation from a previous track or an ideal track or the like.

20 The devices according to the present invention may further be used to support a practice of musical instruments, in particular remote lessons, for example lessons of string instruments, such as fiddles, violins, violas, celli, basses, harps, guitars, banjos, or ukuleles, keyboard instruments, such as pianos, organs, keyboards, harpsichords, harmoniums, or accordions, and/or percussion instruments, such as drums, timpani, marimbas, xylophones, vibraphones, bongos, congas, timbales, djembes or tablas.

25 The devices according to the present invention further may be used in rehabilitation and physiotherapy, in order to encourage training and/or in order to survey and correct movements. Therein, the devices according to the present invention may also be applied for distance diagnostics.

30 Further, the devices according to the present invention may be applied in the field of machine vision. Thus, one or more of the devices according to the present invention may be used e.g. as a passive controlling unit for autonomous driving and or working of robots. In combination with moving robots, the devices according to the present invention may allow for autonomous movement and/or autonomous detection of failures in parts. The devices according to the present invention may also be used for manufacturing and safety surveillance, such as in order to
35 avoid accidents including but not limited to collisions between robots, production parts and living beings. In robotics, the safe and direct interaction of humans and robots is often an issue, as robots may severely injure humans when they are not recognized. Devices according to the present invention may help robots to position objects and humans better and faster and allow a safe interaction. Given the passive nature of the devices according to the present invention, the
40 devices according to the present invention may be advantageous over active devices and/or may be used complementary to existing solutions like radar, ultrasound, 2D cameras, IR detection etc. One particular advantage of the devices according to the present invention is the low likelihood of signal interference. Therefore multiple sensors can work at the same time in the

same environment, without the risk of signal interference. Thus, the devices according to the present invention generally may be useful in highly automated production environments like e.g. but not limited to automotive, mining, steel, etc. The devices according to the present invention can also be used for quality control in production, e.g. in combination with other sensors like 2-D
5 imaging, radar, ultrasound, IR etc., such as for quality control or other purposes. Further, the devices according to the present invention may be used for assessment of surface quality, such as for surveying the surface evenness of a product or the adherence to specified dimensions, from the range of micrometers to the range of meters. Other quality control applications are feasible. In a manufacturing environment, the devices according to the present invention are especially
10 useful for processing natural products such as food or wood, with a complex 3-dimensional structure to avoid large amounts of waste material. Further, devices according to the present invention may be used to monitor the filling level of tanks, silos etc. Further, devices according to the present invention may be used to inspect complex products for missing parts, incomplete parts, loose parts, low quality parts, or the like, such as in automatic optical inspection,
15 such as of printed circuit boards, inspection of assemblies or sub-assemblies, verification of engineered components, engine part inspections, wood quality inspection, label inspections, inspection of medical devices, inspection of product orientations, packaging inspections, food pack inspections, or the like.

20 Further, the devices according to the present invention may be used in vehicles, trains, airplanes, ships, spacecraft and other traffic applications. Thus, besides the applications mentioned above in the context of traffic applications, passive tracking systems for aircraft, vehicles and the like may be named. The use of at least one device according to the present invention, such as at least one detector according to the present invention, for monitoring the speed
25 and/or the direction of moving objects is feasible. Specifically, the tracking of fast moving objects on land, sea and in the air including space may be named. The at least one device according to the present invention, such as the at least one detector according to the present invention, specifically may be mounted on a still-standing and/or on a moving device. An output signal of the at least one device according to the present invention can be combined e.g. with a
30 guiding mechanism for autonomous or guided movement of another object. Thus, applications for avoiding collisions or for enabling collisions between the tracked and the steered object are feasible. The devices according to the present invention generally are useful and advantageous due to the low calculation power required, the instant response and due to the passive nature of the detection system which generally is more difficult to detect and to disturb as compared to
35 active systems, like e.g. radar. The devices according to the present invention are particularly useful but not limited to e.g. speed control and air traffic control devices. Further, the devices according to the present invention may be used in automated tolling systems for road charges.

40 The devices according to the present invention generally may be used in passive applications. Passive applications include guidance for ships in harbors or in dangerous areas, and for aircraft when landing or starting. Therein, fixed, known active targets may be used for precise guidance. The same can be used for vehicles driving on dangerous but well defined routes, such as mining vehicles. Further, the devices according to the present invention may be used to

detect rapidly approaching objects, such as cars, trains, flying objects, animals, or the like. Further, the devices according to the present invention can be used for detecting velocities or accelerations of objects, or to predict the movement of an object by tracking one or more of its position, speed, and/or acceleration depending on time.

5

Further, as outlined above, the devices according to the present invention may be used in the field of gaming. Thus, the devices according to the present invention can be passive for use with multiple objects of the same or of different size, color, shape, etc., such as for movement detection in combination with software that incorporates the movement into its content. In particular, applications are feasible in implementing movements into graphical output. Further, applications of the devices according to the present invention for giving commands are feasible, such as by using one or more of the devices according to the present invention for gesture or facial recognition. The devices according to the present invention may be combined with an active system in order to work under e.g. low light conditions or in other situations in which enhancement of the surrounding conditions is required. Additionally or alternatively, a combination of one or more devices according to the present invention with one or more IR or VIS light sources is possible. A combination of a detector according to the present invention with special devices is also possible, which can be distinguished easily by the system and its software, e.g. and not limited to, a special color, shape, relative position to other devices, speed of movement, light, frequency used to modulate light sources on the device, surface properties, material used, reflection properties, transparency degree, absorption characteristics, etc. The device can, amongst other possibilities, resemble a stick, a racquet, a club, a gun, a knife, a wheel, a ring, a steering wheel, a bottle, a ball, a glass, a vase, a spoon, a fork, a cube, a dice, a figure, a puppet, a teddy, a beaker, a pedal, a switch, a glove, jewelry, a musical instrument or an auxiliary device for playing a musical instrument, such as a plectrum, a drumstick or the like. Other options are feasible.

Further, the devices according to the present invention may be used to detect and or track objects that emit light by themselves, such as due to high temperature or further light emission processes. The light-emitting part may be an exhaust stream or the like. Further, the devices according to the present invention may be used to track reflecting objects and analyze the rotation or orientation of these objects.

Further, the devices according to the present invention generally may be used in the field of building, construction and cartography. Thus, generally, one or more devices according to the present invention may be used in order to measure and/or monitor environmental areas, e.g. countryside or buildings. Therein, one or more devices according to the present invention may be combined with other methods and devices or can be used solely in order to monitor progress and accuracy of building projects, changing objects, houses, etc. The devices according to the present invention can be used for generating three-dimensional models of scanned environments, in order to construct maps of rooms, streets, houses, communities or landscapes, both from ground or from air. Potential fields of application may be construction, cartography, real estate management, land surveying or the like. As an example, the devices according to the

present invention may be used in drones or multicopters to monitor buildings, production sites, chimneys, agricultural production environments such as fields, production plants, or landscapes, to support rescue operations, to support work in dangerous environments, to support fire brigades in a burning location indoors or outdoors, or to find or monitor one or more persons or animals, or the like, or for entertainment purposes, such as a drone following and recording one or more persons doing sports such as skiing or cycling or the like, which could be realized by following a helmet, a mark, a beacon device, or the like. Devices according to the present invention could be used recognize obstacles, follow a predefined route, follow an edge, a pipe, a building, or the like, or to record a global or local map of the environment. Further, devices according to the present invention could be used for indoor or outdoor localization and positioning of drones, for stabilizing the height of a drone indoors where barometric pressure sensors are not accurate enough, or for the interaction of multiple drones such as concertized movements of several drones or recharging or refueling in the air or the like.

Further, the devices according to the present invention may be used within an interconnecting network of home appliances such as CHAIN (Cedec Home Appliances Interoperating Network) to interconnect, automate, and control basic appliance-related services in a home, e.g. energy or load management, remote diagnostics, pet related appliances, child related appliances, child surveillance, appliances related surveillance, support or service to elderly or ill persons, home security and/or surveillance, remote control of appliance operation, and automatic maintenance support. Further, the devices according to the present invention may be used in heating or cooling systems such as an air-conditioning system, to locate which part of the room should be brought to a certain temperature or humidity, especially depending on the location of one or more persons. Further, the devices according to the present invention may be used in domestic robots, such as service or autonomous robots which may be used for household chores. The devices according to the present invention may be used for a number of different purposes, such as to avoid collisions or to map the environment, but also to identify a user, to personalize the robot's performance for a given user, for security purposes, or for gesture or facial recognition. As an example, the devices according to the present invention may be used in robotic vacuum cleaners, floor-washing robots, dry-sweeping robots, ironing robots for ironing clothes, animal litter robots, such as cat litter robots, security robots that detect intruders, robotic lawn mowers, automated pool cleaners, rain gutter cleaning robots, window washing robots, toy robots, telepresence robots, social robots providing company to less mobile people, or robots translating and speech to sign language or sign language to speech. In the context of less mobile people, such as elderly persons, household robots with the devices according to the present invention may be used for picking up objects, transporting objects, and interacting with the objects and the user in a safe way. Further, the devices according to the present invention may be used in robots operating with hazardous materials or objects or in dangerous environments. As a non-limiting example, the devices according to the present invention may be used in robots or unmanned remote-controlled vehicles to operate with hazardous materials such as chemicals or radioactive materials especially after disasters, or with other hazardous or potentially hazardous objects such as mines, unexploded arms, or the like, or to operate in or to investigate inse-

cure environments such as near burning objects or post disaster areas or for manned or unmanned rescue operations in the air, in the sea, underground, or the like.

5 Further, devices according to the present invention may be used for navigation purposes, where Global Positioning Systems (GPS) are not sufficiently reliable. GPS signals commonly use radio waves that are can be blocked or difficult to receive indoors or outdoors in valleys or in forests below the treeline. Further, especially in unmanned autonomous vehicles, the weight of the system may be critical. Especially unmanned autonomous vehicles need high-speed position data for reliable feedback and stability of their control systems. Using devices according to the present invention may allow short time response and positioning without adding weight due to a heavy device.

10 Further, the devices according to the present invention may be used in household, mobile or entertainment devices, such as a refrigerator, a microwave, a washing machine, a window blind or shutter, a household alarm, an air condition device, a heating device, a television, an audio device, a smart watch, a mobile phone, a phone, a dishwasher, a stove or the like, to detect the presence of a person, to monitor the contents or function of the device, or to interact with the person and/or share information about the person with further household, mobile or entertainment devices.

15 Further, the devices according to the present invention may be used to support elderly or disabled persons or persons with limited or no vision, such as in household chores or at work such as in devices for holding, carrying, or picking objects, or in a safety system with optical or acoustical signals signaling obstacles in the environment.

20 The devices according to the present invention may further be used in agriculture, for example to detect and sort out vermin, weeds, and/or infected crop plants, fully or in parts, wherein crop plants may be infected by fungus or insects. Further, for harvesting crops, the devices according to the present invention may be used to detect animals, such as deer, which may otherwise be harmed by harvesting devices. Further, the devices according to the present invention may be used to monitor the growth of plants in a field or greenhouse, in particular to adjust the amount of water or fertilizer or crop protection products for a given region in the field or greenhouse or even for a given plant. Further, in agricultural biotechnology, the devices according to the present invention may be used to monitor the size and shape of plants.

25 Further, devices according to the present invention may be used to automatically remove weeds such as with mechanical means, such as to avoid the use of herbicides. Further, devices according to the present invention may be used in the field of agriculture, in particular to detect and/or locate specific insects such as to decide whether or not to apply a crop protection or fertilization substance, such as to reduce the amount of applied substance or to protect specific groups of animals such as bees.

30 Further, the devices according to the present invention may be combined with sensors to detect chemicals or pollutants, electronic nose chips, microbe sensor chips to detect bacteria or virus-

es or the like, Geiger counters, tactile sensors, heat sensors, or the like. This may for example be used in constructing smart robots which are configured for handling dangerous or difficult tasks, such as in treating highly infectious patients, handling or removing highly dangerous substances, cleaning highly polluted areas, such as highly radioactive areas or chemical spills, or for pest control in agriculture.

One or more devices according to the present invention can further be used for scanning of objects, such as in combination with CAD or similar software, such as for additive manufacturing and/or 3D printing. Therein, use may be made of the high dimensional accuracy of the devices according to the present invention, e.g. in x-, y- or z- direction or in any arbitrary combination of these directions, such as simultaneously. Further, the devices according to the present invention may be used in inspections and maintenance, such as pipeline inspection gauges. Further, in a production environment, the devices according to the present invention may be used to work with objects of a badly defined shape such as naturally grown objects, such as sorting vegetables or other natural products by shape or size or cutting products such as meat or objects that are manufactured with a precision that is lower than the precision needed for a processing step.

Further the devices according to the present invention may be used in local navigation systems to allow autonomously or partially autonomously moving vehicles or multicopters or the like through an indoor or outdoor space. A non-limiting example may comprise vehicles moving through an automated storage for picking up objects and placing them at a different location. Indoor navigation may further be used in shopping malls, retail stores, museums, airports, or train stations, to track the location of mobile goods, mobile devices, baggage, customers or employees, or to supply users with a location-specific information, such as the current position on a map, or information on goods sold, or the like.

Further, the devices according to the present invention may be used to ensure safe driving of motorcycles such as driving assistance for motorcycles by monitoring speed, inclination, upcoming obstacles, unevenness of the road, or curves or the like. Further, the devices according to the present invention may be used in trains or trams to avoid collisions.

Further, the devices according to the present invention may be used in handheld devices, such as for scanning packaging or parcels to optimize a logistics process. Further, the devices according to the present invention may be used in further handheld devices such as personal shopping devices, RFID-readers, handheld devices for use in hospitals or health environments such as for medical use or to obtain, exchange or record patient or patient health related information, smart badges for retail or health environments, or the like.

As outlined above, the devices according to the present invention may further be used in manufacturing, quality control or identification applications, such as in product identification or size identification (such as for finding an optimal place or package, for reducing waste etc.). Further, the devices according to the present invention may be used in logistics applications. Thus, the

5 devices according to the present invention may be used for optimized loading or packing containers or vehicles. Further, the devices according to the present invention may be used for monitoring or controlling of surface damages in the field of manufacturing, for monitoring or controlling rental objects such as rental vehicles, and/or for insurance applications, such as for assessment of damages. Further, the devices according to the present invention may be used for identifying a size of material, object or tools, such as for optimal material handling, especially in combination with robots. Further, the devices according to the present invention may be used for process control in production, e.g. for observing filling level of tanks. Further, the devices according to the present invention may be used for maintenance of production assets like, but not limited to, tanks, pipes, reactors, tools etc. Further, the devices according to the present invention may be used for analyzing 3D-quality marks. Further, the devices according to the present invention may be used in manufacturing tailor-made goods such as tooth inlays, dental braces, prosthesis, clothes or the like. The devices according to the present invention may also be combined with one or more 3D-printers for rapid prototyping, 3D-copying or the like. Further, the devices according to the present invention may be used for detecting the shape of one or more articles, such as for anti-product piracy and for anti-counterfeiting purposes.

20 Thus, specifically, the present application may be applied in the field of photography. Thus, the detector may be part of a photographic device, specifically of a digital camera. Specifically, the detector may be used for 3D photography, specifically for digital 3D photography. Thus, the detector may form a digital 3D camera or may be part of a digital 3D camera. As used herein, the term photography generally refers to the technology of acquiring image information of at least one object. As further used herein, a camera generally is a device adapted for performing photography. As further used herein, the term digital photography generally refers to the technology of acquiring image information of at least one object by using a plurality of light-sensitive elements adapted to generate electrical signals indicating an intensity and/or color of illumination, preferably digital electrical signals. As further used herein, the term 3D photography generally refers to the technology of acquiring image information of at least one object in three spatial dimensions. Accordingly, a 3D camera is a device adapted for performing 3D photography. The camera generally may be adapted for acquiring a single image, such as a single 3D image, or may be adapted for acquiring a plurality of images, such as a sequence of images. Thus, the camera may also be a video camera adapted for video applications, such as for acquiring digital video sequences.

35 Thus, generally, the present invention further refers to a camera, specifically a digital camera, more specifically a 3D camera or digital 3D camera, for imaging at least one object. As outlined above, the term imaging, as used herein, generally refers to acquiring image information of at least one object. The camera comprises at least one detector according to the present invention. The camera, as outlined above, may be adapted for acquiring a single image or for acquiring a plurality of images, such as image sequence, preferably for acquiring digital video sequences. Thus, as an example, the camera may be or may comprise a video camera. In the latter case, the camera preferably comprises a data memory for storing the image sequence.

As used within the present invention, the expression "position" generally refers to at least one item of information regarding one or more of an absolute position and an orientation of one or more points of the object. Thus, specifically, the position may be determined in a coordinate system of the detector, such as in a Cartesian coordinate system. Additionally or alternatively, however, other types of coordinate systems may be used, such as polar coordinate systems and/or spherical coordinate systems.

As outlined above and as will be outlined in further detail below, the present invention preferably may be applied in the field of human-machine interfaces, in the field of sports and/or in the field of computer games. Thus, preferably, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat, an article of clothing, a hat, a shoe. Other embodiments are feasible.

As used herein, the object generally may be an arbitrary object, chosen from a living object and a non-living object. Thus, as an example, the at least one object may comprise one or more articles and/or one or more parts of an article. Additionally or alternatively, the object may be or may comprise one or more living beings and/or one or more parts thereof, such as one or more body parts of a human being, e.g. a user, and/or an animal.

With regard to the coordinate system for determining the position of the object, which may be a coordinate system of the detector, the detector may constitute a coordinate system in which an optical axis of the detector forms the z-axis and in which, additionally, an x-axis and a y-axis may be provided which are perpendicular to the z-axis and which are perpendicular to each other. As an example, the detector and/or a part of the detector may rest at a specific point in this coordinate system, such as at the origin of this coordinate system. In this coordinate system, a direction parallel or antiparallel to the z-axis may be regarded as a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. An arbitrary direction perpendicular to the longitudinal direction may be considered a transversal direction, and an x- and/or y-coordinate may be considered a transversal coordinate.

Alternatively, other types of coordinate systems may be used. Thus, as an example, a polar coordinate system may be used in which the optical axis forms a z-axis and in which a distance from the z-axis and a polar angle may be used as additional coordinates. Again, a direction parallel or antiparallel to the z-axis may be considered a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. Any direction perpendicular to the z-axis may be considered a transversal direction, and the polar coordinate and/or the polar angle may be considered a transversal coordinate.

The detector may be a device configured for providing at least one item of information on the position of the at least one object and/or a part thereof. Thus, the position may refer to an item of information fully describing the position of the object or a part thereof, preferably in the coordinate system of the detector, or may refer to a partial information, which only partially describes

the position. The detector generally may be a device adapted for detecting light beams, such as the light beams propagating from the beacon devices towards the detector.

The evaluation device and the detector may fully or partially be integrated into a single device.

- 5 Thus, generally, the evaluation device also may form part of the detector. Alternatively, the evaluation device and the detector may fully or partially be embodied as separate devices. The detector may comprise further components.

- 10 The detector may be a stationary device or a mobile device. Further, the detector may be a stand-alone device or may form part of another device, such as a computer, a vehicle or any other device. Further, the detector may be a hand-held device. Other embodiments of the detector are feasible.

- 15 The detector specifically may be used to record a light-field behind a lens or lens system of the detector, comparable to a plenoptic or light-field camera. Thus, specifically, the detector may be embodied as a light-field camera adapted for acquiring images in multiple focal planes, such as simultaneously. The term light-field, as used herein, generally refers to the spatial light propagation of light inside the detector such as inside a camera. The detector according to the present invention, specifically having a stack of optical sensors, may have the capability of directly recording a light-field within the detector or camera, such as behind a lens. The plurality of sensors may record images at different distances from the lens. Using, e.g., convolution-based algorithms such as "depth from focus" or "depth from defocus", the propagation direction, focus points, and spread of the light behind the lens can be modeled. From the modeled propagation of light behind the lens, images at various distances to the lens can be extracted, the depth of field can be optimized, pictures that are in focus at various distances can be extracted, or distances of objects can be calculated. Further information may be extracted.

- 30 The use of several optical sensors further allows for correcting lens errors in an image processing step after recording the images. Optical instruments often become expensive and challenging in construction, when lens errors need to be corrected. These are especially problematic in microscopes and telescopes. In microscopes, a typical lens error is that rays of varying distance to the optical axis are distorted differently (spherical aberration). In telescopes, varying the focus may occur from differing temperatures in the atmosphere. Static errors such as spherical aberration or further errors from production may be corrected by determining the errors in a calibration step and then using a fixed image processing such as fixed set of pixels and sensor, or more involved processing techniques using light propagation information. In cases in which lens errors are strongly time-dependent, i.e. dependent on weather conditions in telescopes, the lens errors may be corrected by using the light propagation behind the lens, calculating extended depth of field images, using depth from focus techniques, and others.

- 40 The detector according to the present invention may further allow for color detection. For color detection, a plurality of optical sensors having different spectral properties may be used, and sensor signals of these optical sensors may be compared.

5 The evaluation device may be or may comprise one or more integrated circuits, such as one or more application-specific integrated circuits (ASICs), and/or one or more data processing devices, such as one or more computers, preferably one or more microcomputers and/or microcontrollers, Field Programmable Arrays, or Digital Signal Processors. Additional components may be comprised, such as one or more preprocessing devices and/or data acquisition devices, such as one or more devices for receiving and/or preprocessing of the sensor signals, such as one or more AD-converters and/or one or more filters. Further, the evaluation device may comprise one or more measurement devices, such as one or more measurement devices for measuring electrical currents and/or electrical voltages. Further, the evaluation device may comprise one or more data storage devices. Further, the evaluation device may comprise one or more interfaces, such as one or more wireless interfaces and/or one or more wire-bound interfaces.

15 The at least one evaluation device may be adapted to perform at least one computer program, such as at least one computer program adapted for performing or supporting one or more or even all of the method steps of the method according to the present invention. As an example, one or more algorithms may be implemented which, by using the sensor signals as input variables, may determine the position of the object.

20 The evaluation device can be connected to or may comprise at least one further data processing device that may be used for one or more of displaying, visualizing, analyzing, distributing, communicating or further processing of information, such as information obtained by the optical sensor and/or by the evaluation device. The data processing device, as an example, may be connected or incorporate at least one of a display, a projector, a monitor, an LCD, a TFT, a loudspeaker, a multichannel sound system, an LED pattern, or a further visualization device. It may further be connected or incorporate at least one of a communication device or communication interface, a connector or a port, capable of sending encrypted or unencrypted information using one or more of email, text messages, telephone, Bluetooth, Wi-Fi, infrared or internet interfaces, ports or connections. It may further be connected or incorporate at least one of a processor, a graphics processor, a CPU, an Open Multimedia Applications Platform (OMAP™), an integrated circuit, a system on a chip such as products from the Apple A series or the Samsung S3C2 series, a microcontroller or microprocessor, one or more memory blocks such as ROM, RAM, EEPROM, or flash memory, timing sources such as oscillators or phase-locked loops, counter-timers, real-time timers, or power-on reset generators, voltage regulators, power management circuits, or DMA controllers. Individual units may further be connected by buses such as AMBA buses or be integrated in an Internet of Things or Industry 4.0 type network.

40 The evaluation device and/or the data processing device may be connected by or have further external interfaces or ports such as one or more of serial or parallel interfaces or ports, USB, Centronics Port, FireWire, HDMI, Ethernet, Bluetooth, RFID, Wi-Fi, USART, or SPI, or analogue interfaces or ports such as one or more of ADCs or DACs, or standardized interfaces or ports to further devices such as a 2D-camera device using an RGB-interface such as CameraLink. The

evaluation device and/or the data processing device may further be connected by one or more of interprocessor interfaces or ports, FPGA-FPGA-interfaces, or serial or parallel interfaces ports. The evaluation device and the data processing device may further be connected to one or more of an optical disc drive, a CD-RW drive, a DVD+RW drive, a flash drive, a memory card, a disk drive, a hard disk drive, a solid state disk or a solid state hard disk.

The evaluation device and/or the data processing device may be connected by or have one or more further external connectors such as one or more of phone connectors, RCA connectors, VGA connectors, hermaphrodite connectors, USB connectors, HDMI connectors, 8P8C connectors, BCN connectors, IEC 60320 C14 connectors, optical fiber connectors, D-subminiature connectors, RF connectors, coaxial connectors, SCART connectors, XLR connectors, and/or may incorporate at least one suitable socket for one or more of these connectors.

Possible embodiments of a single device incorporating one or more of the detectors according to the present invention, the evaluation device or the data processing device, such as incorporating one or more of the optical sensor, optical systems, evaluation device, communication device, data processing device, interfaces, system on a chip, display devices, or further electronic devices, are: mobile phones, personal computers, tablet PCs, televisions, game consoles or further entertainment devices. In a further embodiment, the 3D-camera functionality which will be outlined in further detail below may be integrated in devices that are available with conventional 2D-digital cameras, without a noticeable difference in the housing or appearance of the device, where the noticeable difference for the user may only be the functionality of obtaining and/or processing 3D information.

Specifically, an embodiment incorporating the detector and/or a part thereof such as the evaluation device and/or the data processing device may be: a mobile phone incorporating a display device, a data processing device, the optical sensor, optionally the sensor optics, and the evaluation device, for the functionality of a 3D camera. The detector according to the present invention specifically may be suitable for integration in entertainment devices and/or communication devices such as a mobile phone.

A further embodiment of the present invention may be an incorporation of the detector or a part thereof such as the evaluation device and/or the data processing device in a device for use in automotive, for use in autonomous driving or for use in car safety systems such as Daimler's Intelligent Drive system, wherein, as an example, a device incorporating one or more of the optical sensors, optionally one or more optical systems, the evaluation device, optionally a communication device, optionally a data processing device, optionally one or more interfaces, optionally a system on a chip, optionally one or more display devices, or optionally further electronic devices may be part of a vehicle, a car, a truck, a train, a bicycle, an airplane, a ship, a motorcycle. In automotive applications, the integration of the device into the automotive design may necessitate the integration of the optical sensor, optionally optics, or device at minimal visibility from the exterior or interior. The detector or a part thereof such as the evaluation device

and/or the data processing device may be especially suitable for such integration into automotive design.

As used herein, the term light generally refers to electromagnetic radiation in one or more of the visible spectral range, the ultraviolet spectral range and the infrared spectral range. Therein, the term visible spectral range generally refers to a spectral range of 380 nm to 780 nm. The term infrared spectral range generally refers to electromagnetic radiation in the range of 780 nm to 1 mm, preferably in the range of 780 nm to 3.0 micrometers. The term ultraviolet spectral range generally refers to electromagnetic radiation in the range of 1 nm to 380 nm, preferably in the range of 100 nm to 380 nm. Preferably, light as used within the present invention is visible light, i.e. light in the visible spectral range.

The term light beam generally may refer to an amount of light emitted and/or reflected into a specific direction. Thus, the light beam may be a bundle of the light rays having a predetermined extension in a direction perpendicular to a direction of propagation of the light beam. Preferably, the light beams may be or may comprise one or more Gaussian light beams such as a linear combination of Gaussian light beams, which may be characterized by one or more Gaussian beam parameters, such as one or more of a beam waist, a Rayleigh-length or any other beam parameter or combination of beam parameters suited to characterize a development of a beam diameter and/or a beam propagation in space.

The detector according to the present invention may further be combined with one or more other types of sensors or detectors. Thus, the detector may further comprise at least one additional detector. The at least one additional detector may be adapted for detecting at least one parameter, such as at least one of: a parameter of a surrounding environment, such as a temperature and/or a brightness of a surrounding environment; a parameter regarding a position and/or orientation of the detector; a parameter specifying a state of the object to be detected, such as a position of the object, e.g. an absolute position of the object and/or an orientation of the object in space. Thus, generally, the principles of the present invention may be combined with other measurement principles in order to gain additional information and/or in order to verify measurement results or reduce measurement errors or noise.

As outlined above, the human-machine interface may comprise a plurality of beacon devices which are adapted to be at least one of directly or indirectly attached to the user and held by the user. Thus, the beacon devices each may independently be attached to the user by any suitable means, such as by an appropriate fixing device. Additionally or alternatively, the user may hold and/or carry the at least one beacon device or one or more of the beacon devices in his or her hands and/or by wearing the at least one beacon device and/or a garment containing the beacon device on a body part.

The beacon device generally may be an arbitrary device which may be detected by the at least one detector and/or which facilitates detection by the at least one detector. Thus, as outlined above or as will be outlined in further detail below, the beacon device may be an active beacon

device adapted for generating the at least one light beam to be detected by the detector, such as by having one or more illumination sources for generating the at least one light beam. Additionally or alternatively, the beacon device may fully or partially be designed as a passive beacon device, such as by providing one or more reflective elements adapted to reflect a light beam generated by a separate illumination source. The at least one beacon device may permanently or temporarily be attached to the user in a direct or indirect way and/or may be carried or held by the user. The attachment may take place by using one or more attachment means and/or by the user himself or herself, such as by the user holding the at least one beacon device by hand and/or by the user wearing the beacon device.

Additionally or alternatively, the beacon devices may be at least one of attached to an object and integrated into an object held by the user, which, in the sense of the present invention, shall be included into the meaning of the option of the user holding the beacon devices. Thus, as will be outlined in further detail below, the beacon devices may be attached to or integrated into a control element which may be part of the human-machine interface and which may be held or carried by the user, and of which the orientation may be recognized by the detector device. Thus, generally, the present invention also refers to a detector system comprising at least one detector device according to the present invention and which, further, may comprise at least one object, wherein the beacon devices are one of attached to the object, held by the object and integrated into the object. As an example, the object preferably may form a control element, the orientation of which may be recognized by a user. Thus, the detector system may be part of the human-machine interface as outlined above or as outlined in further detail below. As an example, the user may handle the control element in a specific way in order to transmit one or more items of information to a machine, such as in order to transmit one or more commands to the machine.

Alternatively, the detector system may be used in other ways. Thus, as an example, the object of the detector system may be different from a user or a body part of the user and, as an example, may be an object which moves independently from the user. As an example, the detector system may be used for controlling apparatuses and/or industrial processes, such as manufacturing processes and/or robotics processes. Thus, as an example, the object may be a machine and/or a machine part, such as a robot arm, the orientation of which may be detected by using the detector system.

The human-machine interface may be adapted in such a way that the detector device generates at least one item of information on the position of the user or of at least one body part of the user. Specifically in case a manner of attachment of the at least one beacon device to the user is known, by evaluating the position of the at least one beacon device, at least one item of information on a position and/or an orientation of the user or of a body part of the user may be gained.

The beacon device preferably is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user. As outlined above, the beacon device may fully or partially be designed as an active beacon device. Thus, the beacon device

may comprise at least one illumination source adapted to generate at least one light beam to be transmitted to the detector, preferably at least one light beam having known beam properties. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

The object, which may form part of the detector system, may generally have an arbitrary shape. Preferably, the object being part of the detector system, as outlined above, may be a control element which may be handled by a user, such as manually. As an example, the control element may be or may comprise at least one element selected from the group consisting of: a glove, a jacket, a hat, shoes, trousers and a suit, a stick that may be held by hand, a bat, a club, a racket, a cane, a toy, such as a toy gun. Thus, as an example, the detector system may be part of the human-machine interface and/or of the entertainment device.

As used herein, an entertainment device is a device which may serve the purpose of leisure and/or entertainment of one or more users, in the following also referred to as one or more players. As an example, the entertainment device may serve the purpose of gaming, preferably computer gaming. Thus, the entertainment device may be implemented into a computer, a computer network or a computer system or may comprise a computer, a computer network or a computer system which runs one or more gaming software programs.

The entertainment device comprises at least one human-machine interface according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed below. The entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface. The at least one item of information may be transmitted to and/or may be used by a controller and/or a computer of the entertainment device. The at least one item of information preferably may comprise at least one command adapted for influencing the course of a game. Thus, as an example, the at least one item of information may include at least one item of information on at least one orientation of the player and/or of one or more body parts of the player, thereby allowing for the player to simulate a specific position and/or orientation and/or action required for gaming. As an example, one or more of the following movements may be simulated and communicated to a controller and/or a computer of the entertainment device: dancing; running; jumping; swinging of a racket; swinging of a bat; swinging of a club; pointing of an object towards another object, such as pointing of a toy gun towards a target.

The entertainment device as a part or as a whole, preferably a controller and/or a computer of the entertainment device, is designed to vary the entertainment function in accordance with the information. Thus, as outlined above, a course of a game might be influenced in accordance with the at least one item of information. Thus, the entertainment device might include one or more controllers which might be separate from the evaluation device of the at least one detector and/or which might be fully or partially identical to the at least one evaluation device or which might even include the at least one evaluation device. Preferably, the at least one controller

might include one or more data processing devices, such as one or more computers and/or microcontrollers.

- As further used herein, a tracking system is a device which is adapted to gather information on a series of past positions of the at least one object and/or at least one part of the object. Additionally, the tracking system may be adapted to provide information on at least one predicted future position and/or orientation of the at least one object or the at least one part of the object. The tracking system may have at least one track controller, which may fully or partially be embodied as an electronic device, preferably as at least one data processing device, more preferably as at least one computer or microcontroller. Again, the at least one track controller may fully or partially comprise the at least one evaluation device and/or may be part of the at least one evaluation device and/or may fully or partially be identical to the at least one evaluation device.
- The tracking system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time, such as by recording groups of data or data pairs, each group of data or data pair comprising at least one position information and at least one time information.
- The tracking system may further comprise the at least one detector system according to the present invention. Thus, besides the at least one detector and the at least one evaluation device and the optional at least one beacon device, the tracking system may further comprise the object itself or a part of the object, such as at least one control element comprising the beacon devices or at least one beacon device, wherein the control element is directly or indirectly attachable to or integratable into the object to be tracked.
- The tracking system may be adapted to initiate one or more actions of the tracking system itself and/or of one or more separate devices. For the latter purpose, the tracking system, preferably the track controller, may have one or more wireless and/or wire-bound interfaces and/or other types of control connections for initiating at least one action. Preferably, the at least one track controller may be adapted to initiate at least one action in accordance with at least one actual position of the object. As an example, the action may be selected from the group consisting of: a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.
- As an example of application of a tracking system, the tracking system may be used for continuously pointing at least one first object to at least one second object even though the first object and/or the second object might move. Potential examples, again, may be found in industrial applications, such as in robotics and/or for continuously working on an article even though the

article is moving, such as during manufacturing in a manufacturing line or assembly line. Additionally or alternatively, the tracking system might be used for illumination purposes, such as for continuously illuminating the object by continuously pointing an illumination source to the object even though the object might be moving. Further applications might be found in communication systems, such as in order to continuously transmit information to a moving object by pointing a transmitter towards the moving object.

The proposed devices and methods provide a large number of advantages over known detectors of this kind. Thus, the detector generally may avoid the shortcomings of the known prior art systems disclosed above. Specifically, the detector may avoid the use of FiP sensors, thereby allowing for e.g. using simple and cheap and commercially available semiconductor sensors such as silicon photodiodes. These photodiodes generally do not show a luminance dependency, and the method disclosed above is generally independent from the brightness of the scenery and/or the brightness of the light spot on the light beam. Consequently, a range of measurement in terms of luminance or total power of the light beam entering the detector is generally larger in the present invention as compared to many of the devices disclosed above. Further, the measurement by using the detector according to the present invention is generally independent from the target spot size, i.e. from either the size of the object, the size of a light spot projected on to the object or the size of a beacon device being one or more of attached to the object, integrated into the object or held by the object.

The detector according to the present invention may be realized as a simple device combining the functionality of distance measurement or measurement of z-coordinates, with the additional option of measuring one or more transversal coordinates, thereby integrating the functionality of a PSD.

The detector specifically may use linear photodetectors, such as the near silicon photodiodes. The use of a beam splitter is optional but is not generally necessary, which allows for using a simple optical setup.

The result of the measurement, i.e. the position determined by the detector such as the at least one longitudinal coordinate, may be rendered widely independent from the brightness of the scenery and/or the brightness of the object, the brightness of the at least one beacon device, the brightness of the at least one illumination source or the total power of the light beam propagating from the object to the detector. Further, due to this independence and wide range of measurement in terms of brightness, reflective objects or non-reflective objects may be used.

When mentioning a range of measurement, the range of measurement may both refer to a range of brightness which may be used with the detector according to the present invention, such as a range of total powers of the light beam, or may refer to a range of distances between the detector and the object which may be measured. Conventional detectors, such as according to one or more of the documents listed above, are typically limited in both ranges of measurement. The use of the combined signal, as mentioned above, contrarily, provides a wide range of

a continuously and monotonously decreasing or increasing functions which may be used to determine the longitudinal coordinate from the combined signal. Consequently, a very wide range of measurement in terms of distance between the object and the detector is given. Similarly, due to the general independence of the combined signal from the total power of the light beam, at least as long as no saturation of the optical sensors is reached, the present invention also provides a very wide range of measurement in terms of brightness, i.e. in terms of total power of the light beam.

Overall, in the context of the present invention, the following embodiments are regarded as preferred:

Embodiment 1: A detector for determining a position of at least one object, the detector having

- at least one sensor element having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor is configured to generate at least one sensor signal in response to an illumination of the light-sensitive area by at least one light beam propagating from the object to the detector;

- at least one evaluation device configured for evaluating the sensor signals, by

- a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;

- b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;

- c) determining at least one combined signal by combining the center signal and the sum signal; and

- d) determining at least one longitudinal coordinate z of the object by evaluating the combined signal.

Embodiment 2: The detector according to the preceding embodiment, wherein the center signal is selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an integral of sensor signals from a group of optical sensors containing the optical sensor having the highest sensor signal and a predetermined group of neighboring optical sensors; an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a predetermined threshold.

Embodiment 3: The detector according to any one of the preceding embodiments, wherein the detector, specifically the evaluation device, is configured for transforming the sensor signals of

the optical sensor, thereby generating secondary optical sensor signals, wherein the evaluation device is configured for performing steps a)-d) by using the secondary optical sensor signals.

5 Embodiment 4: The detector according to the preceding embodiment, wherein the transforming of the sensor signals comprises at least one transformation selected from the group consisting of: a filtering; a selection of at least one region of interest; a formation of a difference image between an image created by the sensor signals and at least one offset; an inversion of sensor signals by inverting an image created by the sensor signals; a formation of a difference image between an image created by the sensor signals at different times; a background correction; a
10 decomposition into color channels; a decomposition into hue, saturation, and brightness channels, a frequency decomposition; a singular value decomposition; applying a Canny edge detector; applying a Laplacian of Gaussian filter; applying a Difference of Gaussian filter; applying a Sobel operator; applying a Laplace operator; applying a Scharr operator; applying a Prewitt operator; applying a Roberts operator; applying a Kirsch operator; applying a high-pass filter; ap-
15 plying a low-pass filter; applying a Fourier transformation; applying a Radon-transformation; applying a Hough-transformation; applying a wavelet-transformation; a thresholding; creating a binary image.

Embodiment 5: The detector according to any one of the preceding embodiments, wherein the
20 evaluation device comprises at least one center detector for detecting the at least one highest sensor signal and/or for forming the center signal.

Embodiment 6: The detector according to the preceding embodiment, wherein the center detec-
25 tor is fully or partially integrated into the sensor element.

Embodiment 7: The detector according to any one of the two preceding embodiments, wherein the center detector is fully or partially embodied in one or both of software or hardware.

Embodiment 8: The detector according to any one of the preceding embodiments, wherein the
30 sum signal is selected from the group consisting of: an average over all sensor signals of the matrix; a sum of all sensor signals of the matrix; an integral of all sensor signals of the matrix; an average over all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of all sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; an integral of all
35 sensor signals of the matrix except for sensor signals from those optical sensors contributing to the center signal; a sum of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; an integral of sensor signals of optical sensors within a predetermined range from the optical sensor having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors being located within a prede-
40 termined range from the optical sensor having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors being located within a predetermined range from the optical sensor having the highest sensor signal.

Embodiment 9: The detector according to the preceding embodiment, wherein the evaluation
45 device comprises at least one summing device for forming the sum signal.

Embodiment 10: The detector according to the preceding embodiment, wherein the summing device is fully or partially integrated into the sensor element.

- 5 Embodiment 11: The detector according to any one of the two preceding embodiments, wherein the summing device is fully or partially embodied in one or both of software or hardware.

Embodiment 12: The detector according to any one of the preceding embodiments, wherein the combined signal is a combined signal Q, derived by one or more of: forming a quotient of the
 10 center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal.

- 15 Embodiment 13: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

- 20 wherein x and y are transversal coordinates, A1 and A2 are areas of the beam profile at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o.

Embodiment 14: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for using at least one predetermined relationship between the
 25 combined signal Q and the longitudinal coordinate for determining the longitudinal coordinate.

Embodiment 15: The detector according to the preceding embodiment, wherein the predetermined relationship is one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship.

30 Embodiment 16: The detector according to any one of the two preceding embodiments, wherein the evaluation device comprises at least one data storage device for storing the predetermined relationship.

35 Embodiment 17: The detector according to any one of the four preceding embodiments, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the combined signal.

40 Embodiment 18: The detector according to the preceding embodiment, wherein the divider is fully or partially embodied as one or both of a software divider or a hardware divider.

Embodiment 19: The detector according to any one of the two preceding embodiments, wherein the divider is fully or partially integrated into the sensor element.

5 Embodiment 20: The detector according to any one of the preceding embodiments, wherein the optical sensors are photodetectors, preferably inorganic photodetectors, more preferably inorganic semiconductor photodetectors, most preferably silicon photodetectors.

10 Embodiment 21: The detector according to any one of the preceding embodiments, wherein the optical sensors are sensitive in the infrared spectral range.

Embodiment 22: The detector according to any one of the preceding embodiments, wherein the matrix comprises one or both of a CCD detector, preferably a CCD detector chip, or a CMOS detector, preferably a CMOS detector chip.

15 Embodiment 23: The detector according to any one of the preceding embodiments, wherein the matrix is a rectangular matrix having at least one row, preferably a plurality of rows, and a plurality of columns.

20 Embodiment 24: The detector according to the preceding embodiment, wherein the rows and columns are oriented essentially perpendicular.

Embodiment 25: The detector according to any one of the two preceding embodiments, wherein the matrix has at least 10 rows, preferably at least 50 rows, more preferably at least 100 rows.

25 Embodiment 26: The detector according to any one of the three preceding embodiments, wherein the matrix has at least 10 columns, preferably at least 50 columns, more preferably at least 100 columns.

30 Embodiment 27: The detector according to any one of the preceding embodiments, wherein the matrix comprises at least 50 optical sensors, preferably at least 100 optical sensors, more preferably at least 500 optical sensors.

35 Embodiment 28: The detector according to any one of the four preceding embodiments, wherein the ratio of the number of rows and the number of columns is close to 1 preferable larger than 1:3, more preferably larger than 1:2.

Embodiment 29: The detector according to any one of the preceding embodiments, wherein the sensor element is oriented essentially perpendicular to an optical axis of the detector.

40 Embodiment 30: The detector according to any one of the preceding embodiments, wherein the optical sensors each have, at least within a range of measurement, a linear signal characteristic such that the respective sensor signals are dependent on the total power of illumination of the respective optical sensor.

45 Embodiment 31: The detector according to any one of the preceding embodiments, wherein the detector further comprises an illumination source for illuminating the object.

Embodiment 32: The detector according to the preceding embodiment, wherein the illumination source is configured for generating an illuminating light beam for illuminating the object, wherein the detector is configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector.

5

Embodiment 33: The detector according to the preceding embodiment, wherein the detector comprises at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

10 Embodiment 34: The detector according to any one of the three preceding embodiments, wherein the illumination source is adapted to generate at least one illumination pattern for illumination of the object, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern or a random point pattern; at least one Sobol pattern; at least one quasiperiodic pattern; at
15 least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern, in particular a rotated hexagonal pattern and/or a displaced hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings.

20 Embodiment 35: The detector according to the preceding embodiment, wherein the optical sensors are adapted to determine at least one reflection pattern, wherein the evaluation device is adapted to select at least one feature of the reflection pattern and to determine the longitudinal coordinate z of the selected feature of the reflection pattern by evaluating the combined signal Q .

25 Embodiment 36: The detector according to any one of the preceding embodiments, wherein the detector further comprises at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensors.

30 Embodiment 37: The detector according to the preceding embodiment, wherein the transfer device comprises one or more of: at least one lens, for example at least one lens selected from the group consisting of at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one
35 beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

Embodiment 38: The detector according to any one of the preceding embodiments, wherein the evaluation device is further configured for determining at least one transversal coordinate of the
40 object by evaluating a transversal position of the at least one optical sensor having the highest sensor signal.

Embodiment 39: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for distinguishing different light beams having different modulations.
45

Embodiment 40: The detector according to any one of the preceding embodiments, wherein the detector comprises at least one illumination source, wherein the illumination source is adapted to illuminate the object with at least one illumination light beam, wherein the illumination source is arranged such that a direction of propagation of the illumination light beam is essentially parallel to the optical axis.

Embodiment 41: The detector according to any one of the preceding embodiments, wherein the detector comprises the at least one illumination source, wherein the illumination source and the optical axis are separated by a small baseline.

Embodiment 42: A detector system for determining a position of at least one object, the detector system comprising at least one detector according to any one of the preceding embodiments, the detector system further comprising at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object.

Embodiment 43: A human-machine interface for exchanging at least one item of information between a user and a machine, wherein the human-machine interface comprises at least one detector system according to the preceding embodiment, wherein the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user and held by the user, wherein the human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to assign to the position at least one item of information.

Embodiment 44: An entertainment device for carrying out at least one entertainment function, wherein the entertainment device comprises at least one human-machine interface according to the preceding embodiment, wherein the entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface, wherein the entertainment device is designed to vary the entertainment function in accordance with the information.

Embodiment 45: A tracking system for tracking a position of at least one movable object, the tracking system comprising at least one detector system according to any one of the preceding embodiments referring to a detector system, the tracking system further comprising at least one track controller, wherein the track controller is adapted to track a series of positions of the object at specific points in time.

Embodiment 46: A scanning system for determining a depth profile of a scenery, the scanning system comprising at least one detector according to any of the preceding embodiments referring to a detector, the scanning system further comprising at least one illumination source adapted to scan the scenery with at least one light beam.

Embodiment 47: A camera for imaging at least one object, the camera comprising at least one detector according to any one of the preceding embodiments referring to a detector.

Embodiment 48: An inertial measurement unit for use in an electronic device, wherein the inertial measurement unit is adapted to receive data determined by at least one detector according to any one of the preceding embodiment referring to a detector, wherein the inertial measurement unit further is adapted to receive data determined by at least one further sensor selected from the group consisting of: a wheel speed sensor, a turn rate sensor, an inclination sensor, an orientation sensor, a motion sensor, a magneto hydro dynamic sensor, a force sensor, an angular sensor, an angular rate sensor, a magnetic field sensor, a magnetometer, an accelerometer; a gyroscope, wherein the inertial measurement unit is adapted to determine by evaluating the data from the detector and the at least one further sensor at least one property of the electronic device selected from the group consisting of: position in space, relative or absolute motion, rotation, acceleration, orientation, angle position, inclination, turn rate, speed.

Embodiment 49: A method for determining a position of at least one object by using at least one detector, the method comprising the following steps:

- illuminating at least one sensor element of the detector with at least one light beam propagating from the object to the detector, the detector having a matrix of optical sensors, the optical sensors each having a light-sensitive area, wherein each optical sensor generates at least one sensor signal in response to the illumination;
- evaluating the sensor signals, by
 - a) determining at least one optical sensor having the highest sensor signal and forming at least one center signal;
 - b) evaluating the sensor signals of the optical sensors of the matrix and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and
 - d) determining at least one longitudinal coordinate z of the object by evaluating the combined signal.

Embodiment 50: The method according to the preceding embodiment, wherein the combined signal is a combined signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal.

Embodiment 51: The method according to the preceding embodiment, wherein the determining the longitudinal coordinate comprises evaluating the combined signal Q , wherein the evaluating the combined signal comprises using at least one predetermined relationship between the combined signal Q and the longitudinal coordinate for determining the longitudinal coordinate.

Embodiment 52: The method according to any one of the preceding method embodiments, wherein the method comprises using the detector according to any one of the preceding claims referring to a detector.

Embodiment 53: A use of the detector according to any one of the preceding embodiments relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface application; a tracking application; a photography application; a logistics application; a machine vision application; a robotics application; a quality control application; a manufacturing application.

Brief description of the figures

Further optional details and features of the invention are evident from the description of preferred exemplary embodiments which follows in conjunction with the dependent claims. In this context, the particular features may be implemented in an isolated fashion or in combination with other features. The invention is not restricted to the exemplary embodiments. The exemplary embodiments are shown schematically in the figures. Identical reference numerals in the individual figures refer to identical elements or elements with identical function, or elements which correspond to one another with regard to their functions.

Specifically, in the figures:

Figures 1 and 2 show different embodiments of a detector according to the present invention;

Figure 3 shows an example of a light spot on a matrix of optical sensors and the evaluation thereof;

Figure 4 shows an exemplary embodiment of a detector according to the present invention; a detector system, a human machine interface, an entertainment device, a tracking system, a scanning system and a camera;

Figure 5 shows an exemplary embodiment of a combined signal Q as a function of a longitudinal coordinate z , for various illumination intensities; and

Figures 6A and 6B show a modification of the embodiment of Figure 2, with an off-axis illumination light beam;

Figure 11 shows an embodiment of a scanning device.

10 Detailed description of the embodiments

In Figure 1, a schematic view of an embodiment of a detector 110 for determining a position of at least one object 112 is depicted. In this case, the object 112 comprises a beacon device 114, from which a light beam 116 propagates towards a sensor element 118. The sensor element 118 comprises a matrix 120 of optical sensors 122, each optical sensor 122 having a light-sensitive area 124 facing the object 112. The light beam 116, as an example, may propagate along an optical axis 126 of the detector 110. Other embodiments, however, are feasible. The optical detector 110, further, may comprise at least one transfer device 128, such as at least one lens and/or at least one lens system, specifically for beam shaping. Consequently, the light beam 116 may be focused, such as in one or more focal points 130, and a beam width of the light beam 116 may depend on a longitudinal coordinate z of the object 112, such as on a distance between the detector 110 and the beacon device 114 and/or the object 112. For details of this beam width dependency on the longitudinal coordinate, reference may be made to one or more of the above-mentioned prior art documents, such as to one or more of WO 2012/110924 A1 and/or WO 2014/097181 A1.

As can be seen in Figure 1, the light beam 116 generates a light spot 132 on the matrix 120. In Figure 3, an exemplary view of the light spot 132 on the matrix 120 is shown. As can be seen, in this exemplary embodiment, the matrix 120 specifically may be a rectangular matrix, with rows numbered by "i", from 1 to n , and with columns, denoted by "j", from 1 to m , with n , m being integers. The center of the light spot 132, in this exemplary embodiment, is located in the sensor element denoted by i^* , j^* . The optical sensors 122 may provide sensor signals s_{ij} to an evaluation device 134 which, out of the sensor signals, determines at least one center signal, denoted symbolically by s_{ij^*} . As outlined in further detail above, for generating the center signal, the evaluation device 134 may comprise at least one center detector 136. As an example, the center detector simply may determine the maximum sensor signal out of the plurality of sensor signals generated by the optical sensors 122. Alternative methods are feasible. Thus, as an example, instead of determining a single maximum optical sensor signal, a plurality of sensor signals may be used for generating the center signal. Thus, as an example, neighboring optical sensors which are adjacent to the optical sensor i^* , j^* may contribute to the center signal, such as optical sensors with the coordinates $i^*-1, \dots, i^*+1$ and $j^*-1, \dots, j^*+1$. These coordinates, in the simple exemplary embodiment, may form a square around the optical sensor i^* , j^* . Instead of a square having a side length of 3, as in this embodiment, other environments around the optical sensor

having the highest sensor signal may be used. Further, additionally or alternatively, the center signal may be generated by adding up and/or averaging over sensor signals within a certain range from the maximum sensor signal which may for example be beneficial to the measurement precision concerning noise such as pixel noise. Further, additionally or alternatively, for the determination of the center signal or sum signal, image processing techniques such as sub-pixel processing, interpolation, normalization or the like may be employed. Other alternatives are feasible. For example, the beam profile may be a trapezoid beam profile and the evaluation device 134 may be adapted to determine an integral of the trapezoid, in particular of a plateau of the trapezoid. Further, when trapezoid beam profiles may be assumed, the evaluation device 134 may be adopted to determine the sum and center signals by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

Further, the evaluation device 134 is configured for determining at least one sum signal out of the sensor signals of the matrix 120. For this purpose, the evaluation device 134 may comprise at least one summing device 138. The summing device 138 may be configured for adding up, integrating or averaging over the sensor signals of the entire matrix 120, of a region of interest within the matrix 120, each option with or without the optical sensors from which the center signal is generated. Thus, in the exemplary embodiment shown in Figure 3, the summing device is simply configured for summing over the sensor signals s_{ij} of the entire matrix 120, except for the center optical detector with the coordinates i^* , j^* . Other options, however, are feasible.

The evaluation device 134 further is configured for forming at least one combined signal out of the center signal and the sum signal. For this purpose, the evaluation device 134, as an example, may comprise at least one combining device 140, such as at least one divider 142. As a very simple embodiment, a quotient Q may be formed, by dividing the center signal by the sum signal or vice versa. Other options are feasible and are given above.

Finally, the evaluation device 134 is configured for determining at least one longitudinal coordinate z of the object by evaluating the combined signal. For this purpose, the evaluation device may comprise at least one further component, such as at least one evaluation component, which is not depicted in the figures. It shall be noted that the components of the evaluation device 134 shown in Figure 3 may fully or partially be embodied in hardware and/or software. Further, the components may fully or partially be embodied as independent or separate components, and/or may fully or partially be embodied as components which are integrated into the sensor element 118.

The embodiment of Figure 3 further shows that, in addition to the longitudinal coordinate z , at least one item of information on a transversal coordinate of the object 112 and/or the beacon device 114 may be generated. Thus, the coordinates i^* and j^* provide additional items of information on a transversal position of the object 112 and/or the beacon device 114. In the setup of Figure 1, the beacon device 114, for the sake of simplicity, is positioned in the center, i.e. on the

optical axis 126. In this case, the light spot 132 is likely to be centered in the middle of the matrix 120. In the embodiment shown in Figure 3, however, as can easily be detected, the light spot 132 is off-centered. This off-centering is characterized by the coordinates i^* , j^* . By using known optical relationships between this off-centering and a transversal position of the object 112 and/or the beacon device 114, such as by using the lens equation, at least one transversal coordinate of the object 112 and/or the beacon device 114 may be generated. This option is also shown in the exemplary embodiment of Figure 3.

In Figure 2, a modification of the embodiment of Figure 1 is shown, which forms an alternative detector 110. The alternative embodiment of the detector 110 widely corresponds to the embodiment shown in Figure 1. Instead of using an active beacon device 114 with light-emitting properties for generating the light beam 116, however, the detector 110 itself comprises at least one illumination source 144. The illumination source 144, as an example, may comprise at least one laser, whereas, in Figure 1, as an example, the beacon device 114 may comprise a light-emitting diode (LED). Other embodiments, however, are feasible. The illumination source 144 may be configured for generating at least one illumination light beam 146 for fully or partially illuminating the object 112. The illumination light beam 146 is fully or partially reflected by the object 112 and travels back towards the detector 110, thereby forming the light beam 116.

As shown in Figure 2, as an example, the illumination light beam 146 may be parallel to the optical axis 126 of the detector 110. Other embodiments, i.e. off-axis illumination and/or illumination at an angle, are feasible, too, as will be shown in the context of Fig. 6A and 6B below. In order to provide an on-axis illumination, as shown in Figure 2, as an example, one or more reflective elements 148 may be used, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms.

Apart from these modifications, the setup of the embodiment in Figure 2 corresponds to the setup in Figure 1. Thus, again, an evaluation device 134 may be used, having e.g. at least one divider 142 for forming the combined signal Q, and, as an example, at least one position evaluation device 143, for deriving the at least one longitudinal coordinate z from the combined signal Q and/or another type of combined signal. It shall be noted that the evaluation device 134, again, may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 136, 138, 140, 142, 143 may fully or partially be embodied by appropriate software components and/or may fully or partially be embodied by hardware components.

The optical sensors 122 of the matrix 120, as an example, may be pixels of a pixelated optical sensor, such as a CCD and/or a CMOS sensor chip. Thus, as an example, the optical sensors 122 may have a side length and/or an equivalent diameter in the range of a few micrometers to several hundred micrometers. It shall be noted, however, that larger pixels or optical sensors 122 may be used. Further, instead of using an integrated sensor element 118 such as a CCD and/or CMOS sensor chip, non-integrated matrices may be used.

Figure 4 shows, in a highly schematic illustration, an exemplary embodiment of a detector 110, e.g. according to the embodiments in Figures 1 or 2. The detector 110, specifically, may be embodied as a camera 149 and/or may be part of a camera 149. The camera 149 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible.

Figure 4 further shows an embodiment of a detector system 150, which, besides the at least one detector 110, comprises one or more beacon devices 114, which, in this example, may be attached to and/or integrated into an object 112, the position of which shall be detected by using the detector 110. Figure 4 further shows an exemplary embodiment of a human-machine interface 151, which comprises the at least one detector system 150 and, further, an entertainment device 152, which comprises the human-machine interface 151. The figure further shows an embodiment of a tracking system 153 for tracking a position of the object 112, which comprises the detector system 150. The components of the devices and systems shall be explained in further detail below.

Figure 4 further shows an exemplary embodiment of a scanning system 154 for scanning a scenery comprising the at least one object 112, such as for scanning the object 112 and/or for determining at least one position of the at least one object 112. The scanning system 154 comprises the at least one detector 110 and, further, optionally, the at least one illumination source 136 as well as, optionally, at least one further illumination source 136, which is not shown. The illumination source 136, generally, may be configured to emit the at least one illumination light beam 138, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 114 and/or on a surface of the object 112. It shall be noted, however, that an active beacon device, as e.g. shown in the setup of Figure 1, may also be used, and, thus, that setups with no integrated illumination source 136 are also feasible. The scanning system 134 may be designed to generate a profile of the scenery including the object 112 and/or a profile of the object 112 and/or may be designed to generate at least one item of information about the distance between the at least one dot and the scanning system 154, specifically the detector 110, by using the at least one detector 110.

As outlined above, an exemplary embodiment of the detector 110 which may be used in the setup of Figure 4 is shown in Figures 1 and 2. Thus, the detector 110, besides the sensor element 118, comprises the at least one evaluation device 134, having, e.g., the at least one center detector 136, the at least one summing device 138, the at least one combining device 140, the at least one divider 142, the at least one position evaluation device 143 and/or combinations thereof. These components, which may optionally be present, are symbolically depicted in Figure 4. The components of the evaluation device 134 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 110. Besides the possibility of fully or partially combining two or more components, one or more of the components of the evaluation device 134 and one or more of the components of the sensor element 118 may be interconnected by one or more connectors 156 and/or by one or more interfaces, as symbolically depicted in Figure 4. Further, the one or more connectors 156 may

comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 156, the evaluation device 134 may fully or partially be integrated into one or both of the sensor element 118 and/or into a housing 158 of the detector 110. Additionally or alternatively, the evaluation device 134 may
5 fully or partially be designed as a separate device.

In this exemplary embodiment, the object 112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 160, the position of which may be manipulated by a user 162. As an example, the object
10 112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 112 are possible. Further, the user 162 himself or herself may be considered as the object 112, the position of which shall be detected.

As outlined above, the detector 110 comprises at least the sensor element 118. The sensor
15 118, wherein one or more of the sensor elements 118 may be provided, may be located inside the housing 158 of the detector 110. Further, the at least one transfer device 128 may be comprised, such as one or more optical systems, preferably comprising one or more lenses.

An opening 164 inside the housing 158, which, preferably, is located concentrically with regard
20 to the optical axis 126 of the detector 110, preferably defines a direction of view 166 of the detector 110. A coordinate system 168 may be defined, in which a direction parallel or antiparallel to the optical axis 126, such as parallel or antiparallel to the direction of view 166, may be defined as a transversal direction. In the coordinate system 168, symbolically depicted in Figure 4,
25 a longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other types of coordinate systems 168 are feasible, such as non-Cartesian coordinate systems.

The detector 110 may comprise the sensor element 118 as well as, optionally, one or more further optical sensors. A non-branched beam path may be used or, alternatively, a branched
30 beam path may be possible, with, e.g., additional optical sensors in one or more additional beam paths, such as by branching off a beam path for at least one transversal detector or transversal sensor for determining the transversal coordinates of the object 112 and/or parts thereof. As outlined above, however, in the context of Figure 3, the at least one transversal coordinate may also be determined by the sensor element 118 itself, such as by determining
35 the transversal coordinates of the center of the light spot 132.

One or more light beams 116 are propagating from the object 112 and/or from one or more of the beacon devices 114, towards the detector 110. The detector 110 is configured for determining a position of the at least one object 112. For this purpose, as outlined above in the context
40 of Figures 1 to 3, the evaluation device 134 may be configured to evaluate the sensor signals provided by the optical sensors 122 of the matrix 120 of the sensor element 118. The detector 110 is adapted to determine a position of the object 112, and the optical sensors 122 are adapted to detect the light beam 116 propagating from the object 112 towards the detector 110,

specifically from one or more of the beacon devices 114. In case no illumination source 136 is used, the beacon devices 114 and/or at least one of these beacon devices 114 may comprise active beacon devices with an integrated illumination source such as light-emitting diodes. In case the illumination source 136 is used, the beacon devices do not necessarily have to be active beacon devices. Contrarily, a reflective surface of the object 112 may be used, such as integrated reflective beacon devices 114 having at least one reflective surface. The light beam 116, directly and/or after being modified by the transfer device 128, such as being focused by one or more lenses, illuminates the sensor element 118. For details of the evaluation, reference may be made to Figures 1 to 3 above.

As outlined above, the determination of the position of the object 112 and/or a part thereof by using the detector 110 may be used for providing a human-machine interface 151, in order to provide at least one item of information to a machine 170. In the embodiments schematically depicted in Figure 4, the machine 170 may be a computer and/or may comprise a computer.

Other embodiments are feasible. The evaluation device 134 may even be fully or partially integrated into the machine 170, such as into the computer.

As outlined above, Figure 4 also depicts an example of a tracking system 153, configured for tracking the position of the at least one object 112 and/or of parts thereof. The tracking system 153 comprises the detector 110 and at least one track controller 172. The track controller 172 may be adapted to track a series of positions of the object 112 at specific points in time. The track controller 172 may be an independent device and/or may fully or partially be integrated into the machine 170, specifically the computer, as indicated in Figure 4, and/or into the evaluation device 134.

Similarly, as outlined above, the human-machine interface 151 may form part of an entertainment device 152. The machine 170, specifically the computer, may also form part of the entertainment device 152. Thus, by means of the user 162 functioning as the object 112 and/or by means of the user 162 handling a control device 160 functioning as the object 112, the user 162 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer game.

In Figure 5, experimental data are shown which demonstrate an exemplary embodiment of the present invention in terms of measurement data. The figure shows a combined signal Q as a function of a longitudinal coordinate z , given in millimeters, for various illumination intensities.

In order to gain the experimental data shown in Figure 5, an experimental setup was used with a sensor element 118 formed by a Basler AC 1920-40GC camera, with a transfer device 128 formed by a Nikkor 50 mm lens.

As a beacon device 114, a light-emitting diode (LED) was used, having a central nominal wavelength of 532 nm. A diffusor was used in front of the LED and a diaphragm, in order to provide a

well-defined light-emitting area having a diameter of 5 mm. The intensity of the LED was varied, by varying a drive current of the LED between 5 mA and 150 mA.

In the experiments, the distance z between the LED and the lens was varied from 300 mm to 1700 mm. The signal of the Basler AC 1920-40GC camera was evaluated by the following procedure. As a center signal, an accumulated signal of an inner circle having a radius of 15 pixels around the optical axis was determined, with the light spot centered at the optical axis. As a sum signal, the sum of the signals of all pixels of the camera within the light spot was generated. A combined signal was formed, by dividing the sum signal by the center signal.

In Figure 5, the solid curves, overlapping, show the combined signal curves for LED currents of 150 mA, 125 mA, 100 mA and 50 mA. As can be seen, there are basically no differences between these curves, within the whole measurement range. This experiment clearly shows that the combined signal is widely independent on the total power of the light beam. Only at lower intensities, the curves may be distinguished. Thus, the dotted curve shows measurements at an LED current of 25 mA, the dashed-dotted line at an LED current of 10 mA, and the dashed line at an LED current of 5 mA. Still, even at these low intensities, the measurement curves are very close to the solid curves, which shows the high tolerances of the measurement.

In Fig. 6A and 6B, an alternative embodiment of the detector 110 is shown which is a modification of the setup shown in Fig. 2. Thus, for most elements and optional details as well as further elements not shown in the schematic Figures 6A and 6B, reference may be made to the description of Fig. 2 above.

In Figure 2, the illumination light beam 146, as discussed above, preferably travels along the optical axis 126, i.e. parallel to the optical axis 126 or even on the optical axis 126. In the setup, the position of the center of the light spot 132 typically does not depend on the z -coordinate of the object 112, such as on a distance between the object 112 and the detector 110. In other words, the diameter or equivalent diameter of the light spot 132 changes with the distance between the object 112 and the detector 110 whereas, typically, the position of the light spot 132 on the matrix 120 does not.

Contrarily, in Fig. 6A and 6B, a setup of the detector 110 is shown in which an illumination light beam 146 travels off-axis, i.e. one or both of at an angle other than 0° with the optical axis 126 or parallel to the optical axis 126 but shifted from the optical axis 126. This embodiment, as will be discussed in further detail below, demonstrates that the method according to the present invention can be further enhanced by increasing the z -dependency of a combined sensor signal. Thus, in Fig. 6A, a side view is shown with two different positions of the object 112, i.e. a first position at z_1 , drawn in solid lines, and a second position at z_2 , drawn in dashed lines. As can be seen, the illumination light beam 146 which, as an example, propagates at an angle of 5° to 30° , e.g. 10° to 20° , with the optical axis 126, hits the object 112 in both cases at different positions. From these points of the object 112 illuminated by the illumination light beam 146, light beams 116 propagate towards the detector 110, wherein, again, the light beam 116 for the

object 112 being located at position z_1 is drawn in solid lines, wherein the light beam 116 for the object 112 being located at position z_2 is drawn in dashed lines.

In Fig. 6B, the matrix 120 is shown in an enlarged fashion. As can be seen in this setup, the position of the light spot 132 moves with the longitudinal position z of the object 112. Thus, not only is the size of the light spot 132 affected by the longitudinal position z but also is the position on the matrix 120 of the light spot 132 changed. In Fig. 6B, this movement of the light spot 132 is denoted by arrow z .

Consequently, by this movement of the light spot 132, the z -dependency of a combined signal taking into account at least two sensor signals of the optical sensor 122 may be increased.

In the situation shown in Fig. 2, the position of the light spot 132 does not depend on z . With a change in z , depending on the optical situation, the spot will become larger or smaller, such as by becoming more diffuse or more focused. In case the spot size increases and the spot becomes more diffuse such that the combined signal $Q = s_{\text{center}}/s_{\text{sum}}$ decreases.

Contrarily, in the situation of Fig. 6A, both the size and the position of the light spot 132 are dependent on the z -coordinate. Thus, the tendency of the z -dependency of the combined signal such as the combined signal Q will be increased. In the situation of Figure 2, depending on the z -coordinate, the sensor signal of at least one optical sensor of the matrix will increase and simultaneously the sensor signal of at least one different sensor will decrease, resulting in the z -dependent combined signal Q . In the situation of Fig. 6A, the position dependency of the light spot 132 can result in three different situations depending on the relative position of light source, optical axis, and sensor, especially in case the center signal and sum signal are determined from one or more optical sensors, whereas the optical sensors used for determining the center signal and sum signal are kept fixed, independent of the z -coordinate and/or position of the light spot: Firstly, the position dependency of the light spot may result in a further decrease of the at least one decreasing sensor signal depending on the z -coordinate, while, simultaneously, the position dependency of the light spot may result in a further increase of the at least one decreasing sensor signal depending on the z -coordinate compared to the situation in Figure 2. Secondly, the position dependency of the light spot may result in a reduced decrease or even increase of the at least one decreasing sensor signal depending on the z -coordinate, while, simultaneously, the position dependency of the light spot may result in a reduced increase or even decrease of the at least one decreasing sensor signal depending on the z -coordinate compared to the situation in Figure 2. Thirdly, the position dependency of the light spot may be as such that the z -dependence of the sensor signals is largely unchanged compared to the situation in Figure 2. However, according to the present invention, object distance is not determined from the position of the light spot on a sensor as done in triangulation methods. Instead, movement of the light spot 132 on the matrix 120 may be used to enhance dynamic of the sensor signals and or the resulting combined signal Q which may result in an enhanced dynamic of the z -dependency.

Figure 6C shows a comparison of two experimental setups using a detector setup according to Figure 6A with a Bi-cell as optical sensors 120 with two light sensitive areas. In a first experimental setup, depending on the relative position of the illumination light source, the optical axis and the sensor, the light spot 132 may move in parallel to the linear boundary of the two optical sensors 120 of the Bi-cell along a direction of movement 174 in dependence of the object distance. Since the direction of movement 174 of the light spot 132 is in parallel to the linear boundary of the two light sensitive areas in dependence of the object distance, the resulting sensor signals are identical to a situation with no movement of the light spot 132 depending on object distance as shown in Figure 2. In a second experimental setup, depending on the relative position of the illumination light source, the optical axis and the sensor, the light spot 132 may move as such that the distance of the center of the light spot 132 to the boundary of the two optical sensors 120 of the Bi-cell changes in dependence of the object distance such as a movement orthogonal to the boundary of the two optical sensors 120 such as a movement along a direction of movement 176 in dependence of the object distance. The detector setup allowing movement of the light spot 132 may be a modification of the setup shown in Figure 6A. Thus, for most elements and optional details as well as further elements, reference may be made to the description of Fig. 6A above. In Figure 6C, the optical sensors 120 may be 1x2 matrix.

Figure 6D shows experimental results of the comparison of the two experimental setups using a detector setup according to Figure 6A, allowing movement of the light spot 132 according to Figure 6C with movement of the light spot depending on the object distance along directions of movement 174 and 176. Curve 178 shows the dependency of quotient Q on the longitudinal coordinate z for the detector setup allowing movement of the light spot 132 along a direction of movement 174 as shown in Figure 6C which is in parallel to the boundary of the optical sensors of the Bi-Cell and, which is a situation equivalent to Figure 2 without a movement of the light spot depending on the object distance. Curve 180 shows the dependency of quotient Q on the longitudinal coordinate z for the detector setup according to Figure 6A and using a detector setup allowing movement of the light spot 186 with movement of the light spot 132 according to Figure 6C with movement of the light spot depending on the object distance along a direction of movement 176. The experimental setup was as follows: The optical sensors 122 may be a 1x2 matrix, in particular a Si-Bi-Cell. The illumination source 144 may be a 950 nm laser with a spot size of 4 mm. The transfer device 128 may have a focal length of 20 mm, e.g. a lens available as Thorlabs Asphere, f= 20 mm. The distance of the object 112 was varied from 0 to 3000 mm. Determination of the longitudinal coordinate z may be possible without allowing movement of the light spot 132. In particular, according to the present invention, movement of the light spot may not be essential for determination of the longitudinal coordinate z. With the detector setup allowing movement of the light spot 132 along a direction 174 or without any movement determination of object distance is possible at very small distance, whereas with movement along a direction 176 determination of object distance is possible for object distance such as distances greater than 500mm.

Figures 7A and 7B show an exemplary embodiment of a detector 110 with a small baseline 182. Figure 7A shows a side view of the detector 110. The detector 110 may comprise the at least one illumination source 144. The illumination source 144 may be adapted to illuminate the object 112 with at least one illumination light beam 146. The illumination light beam 146 may be fully or partially reflected by the object and may travel back towards the optical sensor 122. The illumination source 144 may be arranged such that a direction of propagation of the illumination light beam is essentially parallel to the optical axis 126. The illumination source 144 may be arranged such that a line running in the direction of propagation of the illumination light beam and the optical axis 126 do not intersect in space. The illumination source 144 and the optical axis 126 may be separated by a small baseline 182. The illumination source 144 may be spaced apart from the optical axis 126 by a minimum distance. The minimum distance from the optical axis may be defined by further detector elements such as size and position of the optical sensors and transfer device. Figure 7B shows a front view on the illumination light beam 144 and the transfer device 128. The baseline may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. For example, the detector 110 may be a compact device without further optical elements, wherein the illumination source 144 may be placed as close as possible to an edge of the transfer device 128. Thus, the baseline 182 may be close to half a diameter of the transfer device 128, in particular the lens diameter and housings of lens and light source. The illumination source 144 may be arranged such that the baseline 182 is as small as possible. For example, a distance from the center of the transfer device 128 to the illumination source 144, in particular along a connecting line from the center of the transfer device 128 to the illumination source 144, may be preferably less than 2.5 times a distance from the center of the transfer device 128 to an edge if the transfer device 128, more preferably less than 1.5 times the distance center to edge of the transfer device 128, and most preferably less 1 times the distance center to edge of the transfer device 128.

Referring to Figure 8, the detector 110 such as the detector as described with respect to Figures 1 to 7 may be adapted to determine depth information, in particular absolute depth information, from a radiance ratio of at least two asymmetric regions of a light beam profile on the at least two optical sensors 122. For example, the detector 110 may comprise a plurality of optical sensors arranged in the matrix 120. The detector 110 may be adapted to determine depth information from a radiance ratio of at least two asymmetric regions within an enclosed, in particular, defocused beam profile captured by a single matrix of optical sensors such as a CMOS detector. In particular, the detector 110 may be adapted to determine the depth information using the radiance ratio independent of a certain object size range. As outlined above, this principle is called Distance by Photon Ratio (DPR). In one embodiment, the light beam 116 may illuminate the sensor element with at least one pattern comprising at least one feature point. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. The evaluation device 134 may be configured for deriving the combined signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A_1 and A_2 are areas of the beam profile at the sensor position, and $E(x, y, z_o)$ denotes the beam profile given at the object distance z_o . A_1 may correspond to a full or complete area of a feature point on the optical sensors. A_2 may be a central area of the feature point on the optical sensors. The central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

In the embodiment shown in Figure 8, the light beam 116 propagating from the object 112 to the detector 110 may illuminate the matrix 120 with at least one line pattern 184. The line pattern 184 may be generated by the object 112 for example in response to an illumination by the at least one illumination source 144 with an illumination pattern comprising at least one illumination line pattern. A_1 may correspond to an area with a full line width of the line pattern 184 in the matrix 120. The line pattern 184 in the matrix 120 may be widened and/or displaced compared to the line pattern of the illumination pattern such that a line width in the matrix 120 is increased. In particular, the line width of the line pattern 184 in the matrix 120 may change from one column to another column. A_2 may be a central area of the line pattern 184 in the matrix 120. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern 184 may be segmented in the matrix 120. Each of the columns may comprise center information of intensity in the central area of the line pattern 184 and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern 184.

Referring to Figures 9A and 9B, as outlined above, the detector 110 may comprise the at least one matrix 120 of optical sensors 122. With the aid of such a pixelated imaging device, a defocused beam profile may be subdivided into cross-sections along lines of a certain angle θ and with a distance ω from the origin of ordinates as shown in Figure 9A. Accordingly, the parameterization of a single line would be given by $\omega = x \cos(\theta) + y \sin(\theta)$. The integration of the intensity along parallel lines can be mathematically described by an integral projection $\Re\{\cdot\}$ of the well-known Radon transform which reads

$$\Re_{(\omega, \theta)}\{f(x, y)\} = \iint_{-\infty}^{\infty} f(x, y) \delta(x \cos(\theta) + y \sin(\theta) - \omega) dx dy$$

where δ denotes the Dirac delta function and $f(x, y)$ is the intensity of an enclosed defocused beam profile. The photon ratio R for a given angle θ and projection width ω is then given by

$$R = \frac{\Re_{(\omega, \theta)}\{f'(x, y)\}}{\Re_{(\omega, \theta)}\{f(x, y)\}}$$

with $f'(x, y)$ as the overshined image region highlighted in Fig. 9. The variation of θ may yield different ratios R for skewed object surfaces at a certain distance. It is sufficient to let θ vary in the following interval $\{\theta \in \mathbb{R}_+, \theta < \pi\}$.

- 5 Figures 10A to 10C show three embodiments of a hexagonal illumination pattern. The illumination source 144 may be adapted to generate at least one illumination pattern for illuminating the object 112. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. Specifically, the illumination source 144 may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor
- 10 lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The illumination pattern may comprise at least one feature such as a point or symbol. The illumination pattern may comprise a plurality of features. The illumination pattern may comprise an arrangement of periodic or non-periodic features. The illumination pattern may be generated by ambient light, such as by at least one ambient light source, or by the at least one
- 15 illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, in particular a pseudo-random point pattern, a random point pattern or a quasi random pattern; at least one Sobol pattern; at least one quasi-periodic pattern; at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one triangular pattern; at least one hexagonal pattern; at least one rectangular pattern at least one pattern comprising convex uniform tilings; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines; at least one fringe pattern. For example, the illumination source may be adapted to generate and/or to project a cloud of points. The illumination pattern may comprise regular and/or constant and/or periodic pattern such as a triangular pattern, a rectangular pattern, a hexagonal pattern, or a pattern comprising further convex tilings. The illumination pattern
- 20 may comprise as much as possible features per area such that hexagonal pattern may be preferred. A distance between two features of the illumination pattern and/or an area of the at least one illumination feature may depend on the circle of confusion in the image.
- 25
- 30 The illumination features of the illumination pattern may be arranged such that only few reference features are positioned on an epipolar line. As shown in Figure 10A, the illumination pattern may comprise at least one hexagonal pattern, wherein the individual points are positioned on epipolar lines 186. As shown in Figure 10B, the illumination pattern may comprise at least one hexagonal pattern, wherein the pattern is rotated relative to the baseline. Such a positioning
- 35 of the illumination features allows enhancing distance between the individual points on each epipolar line. For example as shown in Figure 10C, the illumination pattern may comprise at least one displaced hexagonal pattern, wherein individual points of the hexagonal pattern are displaced by a random distance from the regular position, for example orthogonal to the epipolar line of the point. The displacement of the individual points may be smaller than half of the
- 40 distance between two parallel epipolar lines, preferably smaller than one fourth of the distance between two parallel epipolar lines. The displacement of the individual points may be as such that two points are not displaced above each other. Such a positioning allows to enhance the number of possible features per area.

Figure 11 shows an embodiment of a scanning system 154. The scanning system 154 may be adapted as a line scanning device. In particular, the scanning system 154 may comprise at least one sensor line or row of optical sensors 113. Furthermore, the scanning system may comprise the at least one transfer device 128 and the at least one illumination source 144. Triangulation systems require a sufficient baseline, however due to the baseline in the near field no detection may be possible. Near field detection may be possible if the light spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. Thus, in triangulation systems, the non-zero baseline will always lead to a substantial reduction in the measurement range, in the near field, and/or in the far field. Reducing the baseline as possible with the detector according to the present invention will thus always increase the measurement range. Further, these near field and far field problems can be overcome by using the scanning system 154 of Figure 11. The scanning system 154 may be adapted to detect a plurality of light beams 116 propagating from the object 112 to the scanning device 154 on the CMOS line. The light beams 116 may be generated at different position on the object 112 or by movement of the object 112. The scanning system 154 may be adapted to determine at least one longitudinal coordinate for each of the light points by determining the combined signal Q as described above.

Patent claims

1. A detector (110) for determining a position of at least one object (112), the detector (110) having
- 5 - at least one sensor element (118) having a matrix (120) of optical sensors (122), the optical sensors (122) each having a light-sensitive area (124), wherein each optical sensor (122) is configured to generate at least one sensor signal in response to an illumination of the light-sensitive area (124) by at least one light beam (116) propagating from the object (112) to the detector (110);
- 10 - at least one evaluation device (134) configured for evaluating the sensor signals, by
- a) determining at least one optical sensor (122) having the highest sensor signal and forming at least one center signal;
- b) evaluating the sensor signals of the optical sensors (122) of the matrix (120) and forming at least one sum signal;
- 15 c) determining at least one combined signal by combining the center signal and the sum signal; and
- d) determining at least one longitudinal coordinate z of the object (112) by evaluating the combined signal.
- 20 2. The detector (110) according to the preceding claim, wherein the center signal is selected from the group consisting of: the highest sensor signal; an average of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of sensor signals from a group of optical sensors (122) containing the optical sensor (122) having the highest sensor signal and a predetermined group of neighboring optical sensors (122); a
- 25 sum of sensor signals from a group of optical sensors (122) containing the optical sensor (122) having the highest sensor signal and a predetermined group of neighboring optical sensors (122); a sum of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an average of a group of sensor signals being above a predetermined threshold; a sum of a group of sensor signals being above a predetermined threshold; an inte-
- 30 gral of sensor signals from a group of optical sensors (122) containing the optical sensor (122) having the highest sensor signal and a predetermined group of neighboring optical sensors (122); an integral of a group of sensor signals being within a predetermined range of tolerance from the highest sensor signal; an integral of a group of sensor signals being above a pre-
- 35 determined threshold.
3. The detector (110) according to any one of the preceding claims, wherein the sum signal is selected from the group consisting of: an average over all sensor signals of the matrix (120); a sum of all sensor signals of the matrix (120); an integral of all sensor signals of the matrix (120); an average over all sensor signals of the matrix (120) except for sensor signals from those
- 40 optical sensors (122) contributing to the center signal; a sum of all sensor signals of the matrix (120) except for sensor signals from those optical sensors (122) contributing to the center signal; an integral of all sensor signals of the matrix (120) except for sensor signals from those optical sensors (122) contributing to the center signal; a sum of sensor signals of optical sensors (122) within a predetermined range from the optical sensor (122) having the highest sensor

signal; an integral of sensor signals of optical sensors (122) within a predetermined range from the optical sensor (122) having the highest sensor signal; a sum of sensor signals above a certain threshold of optical sensors (122) being located within a predetermined range from the optical sensor (122) having the highest sensor signal; an integral of sensor signals above a certain threshold of optical sensors (122) being located within a predetermined range from the optical sensor (122) having the highest sensor signal.

4. The detector (110) according to any one of the preceding claims, wherein the combined signal is a combined signal Q, derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa; forming a quotient of a first linear combination of the center signal and the sum signal and a second linear combination of the center signal and the sum signal.

5. The detector (110) according to the preceding claim, wherein the evaluation device (134) is configured for using at least one predetermined relationship between the combined signal Q and the longitudinal coordinate for determining the longitudinal coordinate.

6. The detector (110) according to any one of the two preceding claims, wherein the evaluation device (134) comprises at least one divider (142), wherein the divider (142) is configured for deriving the combined signal.

7. The detector (110) according to any one of the preceding claims, wherein the evaluation device (134) is further configured for determining at least one transversal coordinate of the object (112) by evaluating a transversal position of the at least one optical sensor (122) having the highest sensor signal.

8. The detector (110) according to any one of the preceding claims, wherein the detector (110) comprises at least one illumination source (144), wherein the illumination source (144) is adapted to illuminate the object (112) with at least one illumination light beam, wherein the illumination source (144) is arranged such that a direction of propagation of the illumination light beam is essentially parallel to the optical axis (126).

9. The detector (110) according to any one of the preceding claims, wherein the detector (110) comprises the at least one illumination source (144), wherein the illumination source (144) and the optical axis (126) are separated by a small baseline (182).

10. A detector system (150) for determining a position of at least one object (112), the detector system (150) comprising at least one detector (110) according to any one of the preceding claims, the detector system (150) further comprising at least one beacon device (114) adapted to direct at least one light beam (116) towards the detector (110), wherein the beacon device (114) is at least one of attachable to the object (112), holdable by the object (112) and integratable into the object (112).

11. A human-machine interface (151) for exchanging at least one item of information between a user (162) and a machine (170), wherein the human-machine interface (151) comprises at least one detector system (150) according to the preceding claim, wherein the at least one beacon device (114) is adapted to be at least one of directly or indirectly attached to the user (162) and held by the user (162), wherein the human-machine interface (151) is designed to determine at least one position of the user (162) by means of the detector system (150), wherein the human-machine interface (151) is designed to assign to the position at least one item of information.
12. An entertainment device (152) for carrying out at least one entertainment function, wherein the entertainment device (152) comprises at least one human-machine interface (151) according to the preceding claim, wherein the entertainment device (152) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (151), wherein the entertainment device (152) is designed to vary the entertainment function in accordance with the information.
13. A tracking system (153) for tracking a position of at least one movable object (112), the tracking system (153) comprising at least one detector system (150) according to any one of the preceding claims referring to a detector system (150), the tracking system (153) further comprising at least one track controller (172), wherein the track controller (172) is adapted to track a series of positions of the object (112) at specific points in time.
14. A scanning system (154) for determining a depth profile of a scenery, the scanning system (154) comprising at least one detector (110) according to any of the preceding claims referring to a detector (110), the scanning system (154) further comprising at least one illumination source (144) adapted to scan the scenery with at least one light beam (146, 116).
15. A camera (149) for imaging at least one object (112), the camera (149) comprising at least one detector (110) according to any one of the preceding claims referring to a detector (110).
16. A method for determining a position of at least one object (112) by using at least one detector (110), the method comprising the following steps:
- illuminating at least one sensor element (118) of the detector (110) with at least one light beam (116) propagating from the object (112) to the detector (110), the detector (110) having a matrix (120) of optical sensors (122), the optical sensors (122) each having a light-sensitive area (124), wherein each optical sensor (122) generates at least one sensor signal in response to the illumination;
 - evaluating the sensor signals, by
 - a) determining at least one optical sensor (122) having the highest sensor signal and forming at least one center signal;
 - b) evaluating the sensor signals of the optical sensors (122) of the matrix (120) and forming at least one sum signal;
 - c) determining at least one combined signal by combining the center signal and the sum signal; and

d) determining at least one longitudinal coordinate z of the object (112) by evaluating the combined signal.

- 5 17. The method according to the preceding claim, wherein the combined signal is a combined signal Q , derived by one or more of: forming a quotient of the center signal and the sum signal or vice versa; forming a quotient of a multiple of the center signal and a multiple of the sum signal or vice versa; forming a quotient of a linear combination of the center signal and a linear combination of the sum signal or vice versa.
- 10 18. A use of the detector (110) according to any one of the preceding claims relating to a detector (110), for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a surveillance application; a safety application; a human-machine interface (151) application; a tracking application; a photography application; a logistics application; a machine vision application; a
- 15 robotics application; a quality control application; a manufacturing application.

Detector for optically detecting at least one object

Description

5 Field of the invention

The invention relates to a detector, a detector system and a method for determining a position of at least one object. The invention further relates to a human-machine interface for exchanging at least one item of information between a user and a machine, an entertainment device, a tracking system, a camera, a scanning system, a readout device for optical storage media and various uses of the detector device. The devices, systems, methods and uses according to the present invention specifically may be employed for example in various areas of daily life, gaming, traffic technology, production technology, security technology, photography such as digital photography or video photography for arts, documentation or technical purposes, medical technology or in the sciences. Further, the invention specifically may be used for scanning one or more objects and/or for scanning a scenery, such as for generating a depth profile of an object or of a scenery, e.g. in the field of architecture, metrology, archaeology, arts, medicine, engineering or manufacturing. However, other applications are also possible.

20 Prior art

A large number of optical sensors and photovoltaic devices are known from the prior art. While photovoltaic devices are generally used to convert electromagnetic radiation, for example, ultraviolet, visible or infrared light, into electrical signals or electrical energy, optical detectors are generally used for picking up image information and/or for detecting at least one optical parameter, for example, a brightness.

A large number of optical sensors which can be based generally on the use of inorganic and/or organic sensor materials are known from the prior art. Examples of such sensors are disclosed in US 2007/0176165 A1, US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1 or else in numerous other prior art documents. To an increasing extent, in particular for cost reasons and for reasons of large-area processing, sensors comprising at least one organic sensor material are being used, as described for example in US 2007/0176165 A1. In particular, so-called dye solar cells are increasingly of importance here, which are described generally, for example in WO 2009/013282 A1.

A large number of detectors for detecting at least one object are known on the basis of such optical sensors. Such detectors can be embodied in diverse ways, depending on the respective purpose of use. Examples of such detectors are imaging devices, for example, cameras and/or microscopes. High-resolution confocal microscopes are known, for example, which can be used in particular in the field of medical technology and biology in order to examine biological samples with high optical resolution. Further examples of detectors for optically detecting at least one object are distance measuring devices based, for example, on propagation time methods of corresponding optical signals, for example laser pulses. Further examples of detectors for opti-

cally detecting objects are triangulation systems, by means of which distance measurements can likewise be carried out. Kurt Konolige et al., A Low-Cost Laser Distance Sensor, 2008 IEEE International Conference on Robotics and Automation, Pasadena, CA, USA, May 19-23, 2008, discuss competing technologies using triangulation for planar laser distance sensor (LDS).

5 Structured line devices use a light stripe laser and offset camera to determine range to a set of points. Because the laser energy is spread over a line, it is difficult to achieve accurate range, especially in the presence of ambient light, or with darker objects. Point scan devices for 3D scanning of small objects typically use a scanning mirror to direct a point laser beam and redirect the laser return to an optical receiver. Such devices cannot be miniaturized, and their cost and mechanical fragility will remain high. Centroid point modules typically use position-sensitive devices (PSD). These devices measure the centroid of all light impinging on their surface. Although modulation techniques can be used to offset some of the effects of ambient light, PSDs do not perform well unless the laser spot has a very strong reflection, limiting their use to ranges of a meter or less. Pixel-based point modules search the pixel with maximum signal intensity to determine the position of the light spot on the sensor. Typically CMOS line arrays are used for detection. Konolige et al. introduce a low-cost version of a Pixel-based point module.

US 5 235 377 A describes a measuring apparatus for a camera, wherein light is projected to an object from a projection section. Light reflected on the object is received at a first light receiving section and a second light receiving section arranged to be adjacent to each other. In the first light receiving section, a first and second signals relating to a light receiving position and a quantity of received light are output, and in the second light receiving section, a third signal relating to a quantity of light of the reflected light is output. In a discriminating and calculating section, if it is discriminated that the reflected light is positioned at a place, which is nearer than a predetermined distance, a measuring distance can be calculated from an output ratio of the first signal to the second signal by a measuring calculation circuit. On the other hand, if it is discriminated that the reflected light is positioned at a place, which is farther than the predetermined distance, a measuring distance can be calculated from the output ratio of the sum of the first and second signals to the third signal by the measuring calculation circuit.

US 5 512 997 A describes a distance measuring device having an infrared light-emitting diode by which an infrared light is emitted towards a subject, and first and second linear line sensors on which an image corresponding to light reflected from the subject is formed. The first and second linear line sensors are disposed adjacently and in parallel to each other, and offset by an amount corresponding to half of the predetermined A/D converting step. Analog distance data outputted from the linear line sensors are converted to digital distance data using the predetermined A/D converting step, and then, the digital distance data are added together to obtain a subject distance with a high accuracy.

DE 42 11 875 A1 describes an optical rangefinder with electronic correction for spot eccentricity. The optical rangefinder has an evaluation circuit, which determines if an output distance measurement value is valid or erroneous due to e.g. inclination of object surface. The distance signal is determined by evaluation a position a light spot on a first detector. A second control

signal, which characterizes inclination of the object surface, is determined by evaluating eccentricity of a light spot on a second detector, arranged in a different plane.

WO 2016/051323 A1 describes a detector and a method for optically determining a position of at least one object. The detector comprises at least one optical sensor for determining a position of at least one light beam and at least one evaluation device for generating at least one item of information on a transversal position of the object and at least one item of information on a longitudinal position of the object. The sensor has at least a first electrode and a second electrode. At least one photovoltaic material is embedded in between the first electrode and the second electrode. The first electrode or the second electrode is a split electrode having at least three partial electrodes. The detector and the method can determine three-dimensional coordinates of an object in a fast and efficient way.

In WO 2012/110924 A1, the content of which is herewith included by reference, a detector for optically detecting at least one object is proposed. The detector comprises at least one optical sensor. The optical sensor has at least one sensor region. The optical sensor is designed to generate at least one sensor signal in a manner dependent on an illumination of the sensor region. The sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area. The detector furthermore has at least one evaluation device. The evaluation device is designed to generate at least one item of geometrical information from the sensor signal, in particular at least one item of geometrical information about the illumination and/or the object.

WO 2014/097181 A1, the full content of which is herewith included by reference, discloses a method and a detector for determining a position of at least one object, by using at least one transversal optical sensor and at least one optical sensor. Specifically, the use of sensor stacks is disclosed, in order to determine a longitudinal position of the object with a high degree of accuracy and without ambiguity.

WO 2015/024871 A1, the full content of which is herewith included by reference, discloses an optical detector, comprising:

- at least one spatial light modulator being adapted to modify at least one property of a light beam in a spatially resolved fashion, having a matrix of pixels, each pixel being controllable to individually modify the at least one optical property of a portion of the light beam passing the pixel;
- at least one optical sensor adapted to detect the light beam after passing the matrix of pixels of the spatial light modulator and to generate at least one sensor signal;
- at least one modulator device adapted for periodically controlling at least two of the pixels with different modulation frequencies; and
- at least one evaluation device adapted for performing a frequency analysis in order to determine signal components of the sensor signal for the modulation frequencies.

US 4,767,211 discloses an apparatus for and a method of measuring a boundary surface of a sample in which a ratio of the light quantity of a part of reflected light from a sample which travels in the vicinity of the optical axis of the reflected light, to the light quantity of another part of the reflected light which is directed to a position deviating from the optical axis by a predetermined distance is used to accurately measure a boundary surface of a sample. Since the accuracy of measurement is increased by using the above ratio, light capable of passing through the sample can be used as incident light. Thus, a deep hole in the surface of the sample and a void such as an air bubble in a living being sample, which cannot be measured by the prior art, can be measured very accurately.

WO 2014/198629 A1, the full content of which is herewith included by reference, discloses a detector for determining a position of at least one object, comprising:

- at least one optical sensor, the optical sensor being adapted to detect a light beam propagating from the object towards the detector, the optical sensor having at least one matrix of pixels; and
- at least one evaluation device, the evaluation device being adapted to determine a number N of pixels of the optical sensor which are illuminated by the light beam, the evaluation device further being adapted to determine at least one longitudinal coordinate of the object by using the number N of pixels which are illuminated by the light beam.

Further, generally, for various other detector concepts, reference may be made to WO 2014/198626 A1, WO 2014/198629 A1 and WO 2014/198625 A1, the full content of which is herewith included by reference. Further, referring to potential materials and optical sensors which may also be employed in the context of the present invention, reference may be made to European patent applications EP 15 153 215.7, filed on January 30, 2015, EP 15 157 363.1, filed on March 3, 2015, EP 15 164 653.6, filed on April 22, 2015, EP 15177275.3, filed on July 17, 2015, EP 15180354.1 and EP 15180353.3, both filed on August 10, 2015, and EP 15 185 005.4, filed on September 14, 2015, EP 15 196 238.8 and EP 15 196 239.6, both filed on November 25, 2015, EP 15 197 744.4, filed on December 3, 2015, the full content of all of which is herewith also included by reference.

Further, reference may be made to detector concepts comparing signals of at least two different sources for determining a position of an object. Thus, as an example, reference may be made to EP 16155834.1, EP 16155835.8 or EP 16155845.7, all filed on February 16, 2016, the full disclosure of which is herewith included by reference.

US 5,235,377 A describes a measuring apparatus for a camera. Light is projected to an object from a projection section, and light reflected on the object is received at a first light receiving section and a second light receiving section arranged to be adjacent to each other. In the first light receiving section, a first and second signals relating to a light receiving position and a quantity of received light are output, and in the second light receiving section, a third signal relating to a quantity of light of the reflected light is output. In a discriminating and calculating sec-

tion, if it is discriminated that the reflected light is positioned at a place, which is nearer than a predetermined distance, a measuring distance can be calculated from an output ratio of the first signal to the second signal by a measuring calculation circuit. On the other hand, if it is discriminated that the reflected light is positioned at a place, which is farther than the predetermined distance, a measuring distance can be calculated from the output ratio of the sum of the first and second signals to the third signal by the measuring calculation circuit.

US 5,512,997 A describes a distance measuring device having an infrared light-emitting diode by which an infrared light is emitted towards a subject, and first and second linear line sensors on which an image corresponding to light reflected from the subject is formed. The first and second linear line sensors are disposed adjacently and in parallel to each other, and offset by an amount corresponding to half of the predetermined A/D converting step. Analog distance data outputted from the linear line sensors are converted to digital distance data using the predetermined A/D converting step, and then, the digital distance data are added together.

DE 42 11 875 A1 describes that a beam from e.g. a collimated laser diode passes through crossed cylinder lenses which focus the rays in both sectional planes and adapt the diameter of the beam to the numerical aperture of an objective lens. A mirror section cuts off half of the incident beam and deflects light scattered from the object to a differential photodiode detector. A beam splitter reflects part of the deflected beam on to a four-quadrant photodetector in an orthogonal plane. A first electronic circuit produces a signal corresponding to the position of the light spot on the detector. A second circuit produces a monitoring or correction signal derived from the eccentricity of the spot position.

US 4,767,211 A describes an apparatus for and a method of measuring a boundary surface of a sample are disclosed in which a ratio of the light quantity of a part of reflected light from a sample which travels in the vicinity of the optical axis of the reflected light, to the light quantity of another part of the reflected light which is directed to a position deviating from the optical axis by a predetermined distance is used to measure a boundary surface of a sample.

Despite the advantages implied by the above-mentioned devices and detectors, several technical challenges remain. Thus, generally, a need exists for detectors for detecting a position of an object in space which is both reliable and may be manufactured at low cost. Specifically, a need exists for 3D-sensing concepts. Various known concepts are at least partially based on using so-called FiP sensors, such as several of the above-mentioned concepts. Therein, as an example, large area sensors may be used, in which the individual sensor pixels are significantly larger than the light spot and which are fixed to a specific size. Still, large area sensors in many cases are inherently limited in the use of the FiP measurement principle, specifically in case more than one light spot is to be investigated simultaneously.

A further challenge using FiP detectors is detector area or active area. Typically, for distance measurements, a large active area of the detector is used or even is required. This area, however, may cause noise problems, specifically when the tetralateral conductivity concept is em-

ployed to build a PSD. This often results in poor signal-to-noise-ratios and slow detector response times due to the large capacitance in conjunction with the series resistance of the detector. A further challenge using FiP detectors is cost of manufacturing. Thus, in many cases, typical FiP sensors are expensive, as compared to e.g. conventional Si-based photodiodes. Further, the evaluation of the measurement results of measurements using FiP-sensors remains an issue, specifically in case the total power of a light beam is unknown. In case a plurality of FiP-sensors is used, located at different positions along an axis of propagation of the light beam, a range of measurement typically is limited to the range in between the two positions of the sensors. Further, many FiP-detectors show a luminance dependency which renders the evaluation of the measurement result more difficult, and, additionally, FiP-measurements in many cases are dependent on a target spot size.

Referring to concepts comparing sensor signals generated by at least two different sources such as at least two different optical sensors, one technical challenge remains a reduction of cost of the overall system and, specifically, of the optical sensors. Thus, in many concepts, special optical sensors have to be used, having a dedicated design and placement, which typically requires setting up an expensive optoelectronic semiconductor manufacturing process and a complex assembly scheme.

Problem addressed by the invention

It is therefore an object of the present invention to provide devices and methods facing the above-mentioned technical challenges of known devices and methods. Specifically, it is an object of the present invention to provide cost-efficient devices and methods which reliably may determine a position of an object in space, preferably with a low technical effort and with low requirements in terms of technical resources and cost.

Summary of the invention

This problem is solved by the invention with the features of the independent patent claims. Advantageous developments of the invention, which can be realized individually or in combination, are presented in the dependent claims and/or in the following specification and detailed embodiments.

As used in the following, the terms “have”, “comprise” or “include” or any arbitrary grammatical variations thereof are used in a non-exclusive way. Thus, these terms may both refer to a situation in which, besides the feature introduced by these terms, no further features are present in the entity described in this context and to a situation in which one or more further features are present. As an example, the expressions “A has B”, “A comprises B” and “A includes B” may both refer to a situation in which, besides B, no other element is present in A (i.e. a situation in which A solely and exclusively consists of B) and to a situation in which, besides B, one or more further elements are present in entity A, such as element C, elements C and D or even further elements.

Further, it shall be noted that the terms "at least one", "one or more" or similar expressions indicating that a feature or element may be present once or more than once typically will be used only once when introducing the respective feature or element. In the following, in most cases, when referring to the respective feature or element, the expressions "at least one" or "one or more" will not be repeated, non-withstanding the fact that the respective feature or element may be present once or more than once.

Further, as used in the following, the terms "preferably", "more preferably", "particularly", "more particularly", "specifically", "more specifically" or similar terms are used in conjunction with optional features, without restricting alternative possibilities. Thus, features introduced by these terms are optional features and are not intended to restrict the scope of the claims in any way. The invention may, as the skilled person will recognize, be performed by using alternative features. Similarly, features introduced by "in an embodiment of the invention" or similar expressions are intended to be optional features, without any restriction regarding alternative embodiments of the invention, without any restrictions regarding the scope of the invention and without any restriction regarding the possibility of combining the features introduced in such a way with other optional or non-optional features of the invention.

In a first aspect of the present invention, a detector for determining a position of at least one object is disclosed. As used herein, the term "position" refers to at least one item of information regarding a location and/or orientation of the object and/or at least one part of the object in space. Thus, the at least one item of information may imply at least one distance between at least one point of the object and the at least one detector. As will be outlined in further detail below, the distance may be a longitudinal coordinate or may contribute to determining a longitudinal coordinate of the point of the object. Additionally or alternatively, one or more other items of information regarding the location and/or orientation of the object and/or at least one part of the object may be determined. As an example, additionally, at least one transversal coordinate of the object and/or at least one part of the object may be determined. Thus, the position of the object may imply at least one longitudinal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one transversal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one orientation information of the object, indicating an orientation of the object in space.

The detector comprises:

- at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different spatial offsets, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by a light beam propagating from the object to the detector; and

- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by combining the at least two sensor signals.

As used herein, an “optical sensor” generally refers to a light-sensitive device for detecting a light beam, such as for detecting an illumination and/or a light spot generated by at least one light beam. As further used herein, a “light-sensitive area” generally refers to an area of the optical sensor which may be illuminated externally, by the at least one light beam, in response to which illumination the at least one sensor signal is generated. The light-sensitive area may specifically be located on a surface of the respective optical sensor. Other embodiments, however, are feasible. As used herein, the term “at least two optical sensors, each having at least one light sensitive area” refers to configurations with two single optical sensors each having one light sensitive area and to configurations with one combined optical sensor having at least two light sensitive areas. Thus, the term “optical sensor” furthermore refers to a light-sensitive device configured to generate one output signal, whereas, herein, a light-sensitive device configured to generate two or more output signals, for example at least one bi-cell and/or quadrant diode device, is referred to as two or more optical sensors. As will further be outlined in detail below, each optical sensor, may be embodied such that precisely one light-sensitive area is present in the respective optical sensor, such as by providing precisely one light-sensitive area which may be illuminated, in response to which illumination precisely one uniform sensor signal is created for the whole optical sensor. Thus, each optical sensor may be a single area optical sensor. Other embodiments, however, are feasible. The use of the single area optical sensors, however, renders the setup of the detector specifically simple and efficient. Thus, as an example, commercially available photosensors, such as commercially available silicon photodiodes, each having precisely one sensitive area, may be used in the setup.

As further used herein, a “sensor signal” generally refers to a single signal or a plurality of sensor signals such as a series of sensor signals or a continuous sensor signal, generated by an optical sensor in response to the illumination by the light beam. Specifically, the sensor signal may be or may comprise at least one electrical signal, such as at least one analogue electrical signal and/or at least one digital electrical signal. More specifically, the sensor signal may be or may comprise at least one voltage signal and/or at least one current signal. More specifically, the sensor signal may comprise at least one photocurrent. Further, either raw sensor signals may be used, or the detector, the optical sensor or any other element may be adapted to process or preprocess the sensor signal, thereby generating secondary sensor signals, which may also be used as sensor signals, such as preprocessing by filtering or the like.

The light-sensitive areas specifically may be oriented towards the object. As used herein, the term “is oriented towards the object” generally refers to the situation that the respective surfaces of the light-sensitive areas are fully or partially visible from the object. Specifically, at least one interconnecting line between at least one point of the object and at least one point of the respective light-sensitive area may form an angle with a surface element of the light-sensitive area which is different from 0° , such as an angle in the range of 20° to 90° , preferably 80° to 90° such as 90° . Thus, when the object is located on the optical axis or close to the optical axis, the

light beam propagating from the object towards the detector may be essentially parallel to the optical axis. As used herein, the term “essentially perpendicular” refers to the condition of a perpendicular orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less. Similarly, the term “essentially parallel” refers to the condition of a parallel orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less.

The light beam may propagate from the object towards the detector. As will be outlined in further detail below, the light beam may originate from the object, such as by the object and/or at least one illumination source integrated or attached to the object emitting the light beam, or may originate from a different illumination source, such as from an illumination source directly or indirectly illuminating the object, wherein the light beam is reflected or scattered by the object and, thereby, is at least partially directed towards the detector. The illumination source, as an example, may be or may comprise one or more of an external illumination source, an illumination source integrated into the detector or an illumination source integrated into a beacon device being one or more of attached to the object, integrated into the object or held by the object.

As further used herein, the term “light beam” generally refers to an amount of light, specifically an amount of light traveling essentially in the same direction, including the possibility of the light beam having a spreading angle or widening angle. The light beam specifically may be a Gaussian light beam, as will be outlined in further detail below. Other embodiments are feasible, however.

The optical sensors may be sensitive in one or more of the ultraviolet, the visible or the infrared spectral range. Specifically, the optical sensors each, independently, may be or may comprise at least one element selected from the group consisting of a photodiode, a photocell, a photoconductor, a phototransistor or any combination thereof. Any other type of photosensitive element may be used. As will be outlined in further detail below, the photosensitive element generally may fully or partially be made of inorganic materials and/or may fully or partially be made of organic materials. Most commonly, as will be outlined in further detail below, one or more photodiodes may be used, such as commercially available photodiodes, e.g. inorganic semiconductor photodiodes.

The light-sensitive areas of the optical sensors may overlap, as visible from the object, or may not overlap, i.e. may be placed next to each other without overlap. The light-sensitive areas may be spaced apart from each other or may directly be adjacent.

The detector has an optical axis. As used herein, the term “optical axis” generally refers to a line of symmetry of the optical setup of the detector. In case the detector has a lens or lens system, such as a lens or lens system being part of a transfer system which will be explained in further detail below, the optical axis, as an example, may be an axis of mirror symmetry or rotational symmetry of the lens or lens system. Thus, as will be outlined in further detail below, the detector may comprise at least one transfer system, preferably at least one transfer system having at least one lens. The transfer system, as an example, may comprise at least one beam path, with

the elements of the transfer system in the beam path being located in a rotationally symmetrical fashion with respect to the optical axis. Still, as will also be outlined in further detail below, one or more optical elements located within the beam path may also be off-centered or tilted with respect to the optical axis. In this case, however, the optical axis may be defined sequentially, such as by interconnecting the centers of the optical elements in the beam path, e.g. by interconnecting the centers of the lenses, wherein, in this context, the optical sensors are not counted as optical elements. The optical axis generally may denote the beam path. Therein, the detector may have a single beam path along which a light beam may travel from the object to the optical sensors, or may have a plurality of beam paths. As an example, a single beam path may be given or the beam path may be split into two or more partial beam paths. In the latter case, each partial beam path may have its own optical axis, and the condition noted above generally may refer to each beam path independently. The optical sensors may be located in one and the same beam path or partial beam path. Alternatively, however, the optical sensors may also be located in different partial beam paths. In case the optical sensors are distributed over different partial beam paths, the above-mentioned condition may be described such that at least one first optical sensor is located in at least one first partial beam path, being offset from the optical axis of the first partial beam path by a first spatial offset, and at least one second optical sensor is located in at least one second partial beam path, being offset from the optical axis of the second partial beam path by at least one second spatial offset, wherein the first spatial offset and the second spatial offset are different.

The detector may comprise more than two optical sensors. In any case, i.e. in the case of the detector comprising precisely two optical sensors and in the case of the detector comprising more than two optical sensors, the optical sensors may comprise at least one first optical sensor being spaced apart from the optical axis by a first spatial offset and at least one second optical sensor being spaced apart from the optical axis by a second spatial offset, wherein the first spatial offset and the second spatial offset differ. In case further optical sensors are provided, besides the first and second optical sensors, these additional optical sensors may also fulfill the condition or, alternatively, may be spaced apart from the optical axis by the first spatial offset, by the second spatial offset or by a different spatial offset. The first and second spatial offsets, as an example, may differ by at least a factor of 1.2, more preferably by at least a factor of 1.5, more preferably by at least a factor of two. The spatial offsets may also be zero or may assume negative values, as long as the above-mentioned conditions are fulfilled.

As outlined above, each light-sensitive area has a geometrical center. As used herein, the term "geometrical center" of an area generally may refer to a center of gravity of the area. As an example, if an arbitrary point inside or outside the area is chosen, and if an integral is formed over the vectors interconnecting this arbitrary point with each and every point of the area, the integral is a function of the position of the arbitrary point. When the arbitrary point is located in the geometrical center of the area, the integral of the absolute value of the integral is minimized. Thus, in other words, the geometrical center may be a point inside or outside the area with a minimum overall or sum distance from all points of the area.

Each geometrical center of each light-sensitive area is spaced apart from the optical axis of the detector, such as the optical axis of the beam path or the respective beam path in which the respective optical sensor is located. The distance between the geometrical center and the optical axis is denoted by the term "spatial offset".

5

As outlined above, the optical sensors specifically may be located in one and the same plane, which, preferably, is a plane perpendicular to the optical axis. Other configurations, however, are possible. Thus, two or more of the optical sensors may also be spaced apart in a direction parallel to the optical axis.

10

In a preferred embodiment, which is rather simple and cost-efficiently realizable, the optical sensors are partial diodes of a segmented diode, with a center of the segmented diode being off-centered from the optical axis of the detector. As used herein, the term "partial diode" may comprise several diodes that are connected in series or in parallel. This example is rather simple and cost-efficiently realizable. Thus, as an example, bi-cell diodes or quadrant diodes are widely commercially available at low cost, and driving schemes for these quadrant diodes are generally known. As used herein, the term "bi-cell diode" generally refers to a diode having two partial diodes in one packaging. Bi-cell and quadrant diodes may have two or four separate light sensitive areas, in particular two or four active areas. As an example, the bi-cell diodes may each form independent diodes having the full functionality of a diode. As an example, each of the bi-cell diodes may have a square or rectangular shape, and the two diodes may be placed in one plane such that the two partial diodes, in total, form a 1 x 2 or 2 x 1 matrix having a rectangular shape. In the present invention, however, a new scheme for evaluating the sensor signals of the bi-cell diodes or quadrant diode is proposed, as will be outlined in further detail below. In the present invention, however, a new scheme for evaluating the sensor signals of the bi-cell diodes and the quadrant diode is proposed, as will be outlined in further detail below. Generally, however, the optical sensors specifically may be partial diodes of a quadrant diode, with a center of the quadrant diode being off-centered from the optical axis of the detector. As used herein, the term "quadrant diode" generally refers to a diode having four partial diodes in one packaging. As an example, the four partial diodes may each form independent diodes having the full functionality of a diode. As an example, the four partial diodes may each have a square or rectangular shape, and the four partial diodes may be placed in one plane such that the four partial diodes, in total, form a 2 x 2 matrix having a rectangular or square shape. In a further example, the four partial diodes, in total, may form a 2 x 2 matrix having a circular or elliptical shape. The partial diodes, as an example, may be adjacent, with a minimum separation from one another. However, the separation between adjacent diodes may also be varied to improve the dynamic range of the quotient signal. As an example, the separation between two adjacent diodes may be increased by using an opaque mask. This may reduce the light on one of the diodes relative and/or absolute as compared to the adjacent diode which may increase a quotient of the signal of the two diodes. The rows and columns of the matrix specifically may be arranged in a rectangular fashion. It shall be outlined, however, that other arrangements are feasible, such as nonrectangular arrangements. As an example, circular arrangements are also feasible, wherein the partial diodes are arranged in concentric circles or ellipses about a center

15

20

25

30

35

40

point, hexagonal arrangements, triangular arrangements, polygonal arrangements or combinations thereof are also feasible, wherein the partial diodes are arranged as regular or irregular polygons such as in hexagons or the like.

- 5 Further, arrangements may be feasible, wherein at least one of the partial diodes of a polygonal pattern may be arranged as star shaped element in a triangular pattern and/or striped element in a rectangular pattern, or the like. Further, arrangements may be feasible, wherein the partial diodes of a polygonal pattern are summarized to a larger, unseparated partial diode, such as star shaped partial diodes in a triangular pattern, striped partial diodes in a rectangular pattern, 10 or the like. Further, separated partial diodes may be summarized or connected to a single partial diode such as the corner partial diodes forming a first partial diode and the non-corner partial diodes forming a second partial diode. Further, for example, the matrix may be a single row of partial diodes. Further, arrangements, where the optical sensors and/or at least one of partial diodes may have a star shape and/or circular shape, and/or cross shape may be feasible. For 15 example, at least two of the partial diodes may be arranged in star shaped manner or cross shaped manner, whereas the other partial diodes may be arranged as such that they complete a square or rectangular shape of the optical sensor, so that a square shaped or rectangular shaped substrate can be employed. Other arrangements are feasible.
- 20 In case a quadrant diode is used, having a 2×2 matrix of partial diodes, the center of the quadrant diode specifically may be off-centered or offset from the optical axis. Thus, as an example, the center of the quadrant diodes, which may be an intersection of the geometrical centers of the optical sensors of the quadrant diode, may be off-centered from the optical axis by at least 0.2 mm, more preferably by at least 0.5 mm, more preferably by at least 1.0 mm or even 2.0 25 mm. Similarly, when using other types of optical sensors setups having a plurality of optical sensors, an overall center of the optical sensors may be offset from the optical axis by the same distance.

- As outlined above, bi-cell and quadrant diodes may have two or four separate light sensitive 30 areas, in particular two or four active areas. The light sensitive areas may be separated by a dividing line. The dividing line, for example, of two Si-diodes, can be arranged parallel to the baseline of the detector, in particular parallel to a spot movement on the optical sensors. However, other arrangements are feasible. For example, the quadrant diode may comprise two dividing lines. The dividing lines may be arranged orthogonal to each other. The orthogonal ar- 35 rangement of the dividing lines allows adjusting of the quotient signal for near field and far field applications independently from each other. In addition to determining the quotient signal of sensor signals of two optical sensors of the quadrant diode, the evaluation device may be adapted to determine a second quotient using at least three or all four sensor signals of the quadrant diode. The two quotients can be formed such that two distinct distance ranges are 40 covered. The two quotient signals for the near field and far field may have an overlap region in which both quotient signals allow obtaining reasonable determination of the longitudinal distance z . For example, the quotient signal may be determined by dividing the sensor signals of two top quadrants, also called top segment, by the sensor signals of two bottom quadrants, also

called bottom segment. Using the quotient signal of sensor signals determined by two sensor areas which have a dividing line parallel to the baseline of the detector may allow determining of the quotient without any distance dependent movement of the light spot. In particular, as an example, if the dividing line between the top and bottom segment is parallel to the baseline, the quotient signal determined from top segment divided by bottom segment may be used in the near field, wherein the light spot may illuminate only one of a left or right segment of the quadrant diode. In this case determining the quotient signal by dividing sensor signals of the left and right segments may not be possible. However, determining the quotient by dividing the sensor signals of top and bottom segments may provide a reasonable distance measurement. The quotient signal determined by dividing sensor signals of the left and right segments may be used for far field measurement, wherein the light spot illuminates both left and right segments. Furthermore, the evaluation device may be adapted to determine the quotient signal by dividing sensor signals of opposing segments or neighboring segments. The evaluation device may be adapted to combine the acquired sensor signals of the quadrants such that distance measurement is possible over a wide range with a large resolution.

The detector may comprise at least one quadrant diode comprising four quadrants. For example, an upper left quadrant of the quadrant diode may be denoted "ol", a lower left quadrant "ul", an upper right quadrant may be denoted "or" and a lower right quadrant may be denoted "ur".

The light spot may move from the left in a small distance range to the left in a far distance range. The detector may comprise at least one neutral density filter. The quadrants of the small distance range may be covered by the neutral density filter. In the small distance range the quotient ol/ul may be used to determine the longitudinal coordinate z. In the far distance range a quotient or/ur and/or a quotient from a combination of all quadrants may be used. The neutral density filter allows that objects in the small distance range are adapted to illuminate the optical sensors brighter by constant amplification without saturating the amplifier. At the same time it is possible to obtain in the far distance range more of the signal. Thus, the neutral density filter allows to enhance dynamic of the detector.

Generally, the light-sensitive areas of the optical sensors may have an arbitrary surface area or size. Preferably, however, specifically in view of a simplified evaluation of the sensor signals, the light-sensitive areas of the optical sensors are substantially equal, such as within a tolerance of less than 10%, preferably less than 5% or even less than 1%. This, specifically, is the case in typical commercially available quadrant diodes.

As further used herein, the term evaluation device generally refers to an arbitrary device adapted to perform the named operations, preferably by using at least one data processing device and, more preferably, by using at least one processor and/or at least one application-specific integrated circuit. Thus, as an example, the at least one evaluation device may comprise at least one data processing device having a software code stored thereon comprising a number of computer commands. The evaluation device may provide one or more hardware elements for performing one or more of the named operations and/or may provide one or more processors with software running thereon for performing one or more of the named operations.

Specifically, as will be outlined in further detail below, the evaluation device may be configured to determine the at least one longitudinal coordinate z of the object by using at least one known, determinable or predetermined relationship between sensor signals and/or any secondary signal derived thereof and the longitudinal coordinate. Thus, the evaluation device may be configured for determining at least one combined sensor signal out of the at least two sensor signals, i.e. of the at least one sensor signal of at least one first optical sensor and out of the at least one sensor signal of at least one second optical sensor. As generally used herein, the term “combine” generally may refer to an arbitrary operation in which two or more components such as signals are one or more of mathematically merged in order to form at least one merged combined signal and/or compared in order to form at least one comparison signal or comparison result. As will be outlined in further detail below, the combined sensor signal or secondary signal may be or may comprise at least one quotient signal.

The evaluation device specifically may be configured for deriving at least one quotient signal Q by one or more of: dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals. The evaluation device may further be configured for determining the longitudinal coordinate by evaluating the quotient signal Q . In case more than two sensor signals are provided, as an example, more than one quotient signal may be generated, such as by forming quotient signals of more than one pair of sensor signals.

As an example, Q may simply be determined as

$$Q = s_1/s_2$$

or

$$Q = s_2/s_1,$$

with s_1 denoting a first one of the sensor signals and s_2 denoting a second one of the sensor signals. Additionally or alternatively, Q may be determined as

$$Q = a \cdot s_1 / b \cdot s_2$$

or

$$Q = b \cdot s_2 / a \cdot s_1,$$

with a and b being real numbers which, as an example, may be predetermined or determinable. Additionally or alternatively, Q may be determined as

$$Q = (a \cdot s_1 + b \cdot s_2) / (c \cdot s_1 + d \cdot s_2),$$

with a, b, c and d being real numbers which, as an example, may be predetermined or determinable. As a simple example for the latter, Q may be determined as

$$Q = s_1 / (s_1 + s_2),$$

5

or, as a further example, Q may be determined as

$$Q = (s_1 - s_2) / (s_1 + s_2).$$

10 Other quotient signals are feasible. Thus, as an example, in case more than two optical sensors are provided, the above-mentioned quotient formation may take place between two of the sensor signals generated by these optical sensors or may take place between more than two of the sensor signals. Thus, instead of using the first one of the sensor signals and the second one of the sensor signals in the formulae given above, combined sensor signals may be used for quotient formation.

15

The quotient signal Q generally is an example for an asymmetry parameter denoting an asymmetry or an asymmetric distribution of the light spot generated by the light beam on the light-sensitive areas. The quotient of the two or more optical sensors, such as the two or more photodiodes, may provide a combined signal which typically is monotonously dependent on the distance between the detector and the object from which the light beam travels towards the detector, as will be shown by experimental data below. In addition or as an alternative to the quotient signal, other types of combined functions implementing the sensor signals of two or more sensors in the setup of the present invention may be used, which also may show a dependency on the distance between the object and the detector. The asymmetry or the asymmetry parameter of the light spot, as an example, may be an indication of the width of a light beam. If this asymmetry parameter depends on the distance only, the measurement can be used to determine the distance.

20

25

30 The evaluation device may be configured for deriving the quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals, dividing linear combinations of the sensor signals. The evaluation device may be configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate for determining the longitudinal coordinate. For example, the evaluation device is configured for deriving the quotient signal Q by

35

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A1 and A2 are areas of the beam profile at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o. Area A1 and area A2 may differ. In particular, A1 and A2 are not congruent. Thus, A1 and A2 may differ in one or more of the shape or content. As used herein, the term “beam profile” relates to a spa-

40

tial distribution, in particular in at least one plane perpendicular to the propagation of the light beam, of an intensity of the light beam. The beam profile may be a cross section of the light beam. The beam profile may be selected from the group consisting of a trapezoid beam profile; a triangle beam profile; a conical beam profile and a linear combination of Gaussian beam profiles. Generally the beam profile is dependent on luminance $L(z_0)$ and beam shape $S(x,y;z_0)$,
 $E(x,y;z_0) = L \cdot S$.

Each of the sensor signals may comprise at least one information of at least one area of the beam profile of the light beam. As used herein, the term "area of the beam profile" generally refers to an arbitrary region of the beam profile at the sensor position used for determining the quotient signal Q . The light-sensitive regions may be arranged such that a first sensor signal comprises information of a first area of the beam profile and a second sensor signal comprises information of a second area of the beam profile. The first area of the beam profile and second area of the beam profile may be one or both of adjacent or overlapping regions. The first area of the beam profile and the second area of the beam profile may be not congruent in area.

The evaluation device may be configured to determine and/or to select the first area of the beam profile and the second area of the beam profile. The first area of the beam profile may comprise essentially edge information of the beam profile and the second area of the beam profile may comprise essentially center information of the beam profile. The beam profile may have a center, i.e. a maximum value of the beam profile and/or a center point of a plateau of the beam profile and/or a geometrical center of the light spot, and falling edges extending from the center. The second region may comprise inner regions of the cross section and the first region may comprise outer regions of the cross section. As used herein, the term "essentially center information" generally refers to a low proportion of edge information, i.e. proportion of the intensity distribution corresponding to edges, compared to a proportion of the center information, i.e. proportion of the intensity distribution corresponding to the center. Preferably the center information has a proportion of edge information of less than 10 %, more preferably of less than 5%, most preferably the center information comprises no edge content. As used herein, the term "essentially edge information" generally refers to a low proportion of center information compared to a proportion of the edge information. The edge information may comprise information of the whole beam profile, in particular from center and edge regions. The edge information may have a proportion of center information of less than 10 %, preferably of less than 5%, more preferably the edge information comprises no center content. At least one area of the beam profile may be determined and/or selected as second area of the beam profile if it is close or around the center and comprises essentially center information. At least one area of the beam profile may be determined and/or selected as first area of the beam profile if it comprises at least parts of the falling edges of the cross section. For example, the whole area of the cross section may be determined as first region. The first area of the beam profile may be area A2 and the second area of the beam profile may be area A1.

Other selections of the first area A1 and second area A2 may be feasible. For example, the first area may comprise essentially outer regions of the beam profile and the second area may com-

prise essentially inner regions of the beam profile. For example, in case of a two-dimensional beam profile, the beam profile may be divided in a left part and a right part, wherein the first area may comprise essentially areas of the left part of the beam profile and the second area may comprise essentially areas of the right part of the beam profile.

5

The edge information may comprise information relating to a number of photons in the first area of the beam profile and the center information may comprise information relating to a number of photons in the second area of the beam profile. The evaluation device may be adapted for determining an area integral of the beam profile. The evaluation device may be adapted to determine the edge information by integrating and/or summing of the first area. The evaluation device may be adapted to determine the center information by integrating and/or summing of the second area. For example, the beam profile may be a trapezoid beam profile and the evaluation device may be adapted to determine an integral of the trapezoid. Further, when trapezoid beam profiles may be assumed, the determination of edge and center signals may be replaced by equivalent evaluations making use of properties of the trapezoid beam profile such as determination of the slope and position of the edges and of the height of the central plateau and deriving edge and center signals by geometric considerations.

10

15

20

Additionally or alternatively, the evaluation device may be adapted to determine one or both of center information or edge information from at least one slice or cut of the light spot. This may be realized, for example, by replacing the area integrals in the quotient signal Q by a line integrals along the slice or cut. For improved accuracy, several slices or cuts through the light spot may be used and averaged. In case of an elliptical spot profile, averaging over several slices or cuts may result in an improved distance information.

25

30

The evaluation device may be configured to derive the quotient signal Q by one or more of dividing the edge information and the center information, dividing multiples of the edge information and the center information, dividing linear combinations of the edge information and the center information. Thus, essentially, photon ratios may be used as the physical basis of the method.

35

40

In one embodiment, the light beam propagating from the object to the detector may illuminate the optical sensors with at least one pattern comprising at least one feature point. As used herein, the term "feature point" refers to at least one at least partially extended feature of the pattern. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors. The central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

For example, the light beam propagating from the object to the detector may illuminate the optical sensors with at least one line pattern. The line pattern may be generated by the object, for example in response to an illumination by the at least one illumination source with an illumination pattern comprising the at least one line pattern. A1 may correspond to an area with a full line width of the line pattern on the optical sensors, in particular on the light sensitive area of the optical sensors. The line pattern on the optical sensors may be widened and/or displaced compared to the line pattern of the illumination pattern such that the line width on the optical sensors is increased. In particular, in case of the optical sensors are arranged as a sensor element having at least two columns, the line width of the line pattern on the optical sensors may change from one column to another column. A2 may be a central area of the line pattern on the optical sensors. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. The line pattern may be segmented on the optical sensors. Each column of optical sensors may comprise center information of intensity in the central area of the line pattern and edge information of intensity from regions extending further outwards from the central area to edge regions of the line pattern. For example, the detector may comprise at least two rows of optical sensors, wherein the rows are arranged on top of each other. The line pattern may be imaged parallel to the rows such that the center of the line pattern is fixed or moves only little relative to a dividing line of the rows. The A1 may correspond to an area above the dividing line and A2 may be an area below the dividing line.

The light beam may be a monochromatic light beam. The light beam may comprise a narrow band of wavelengths, preferably the light beam may comprise a single wavelength. The at least one light source may be adapted to generate at least one monochromatic light beam and/or the detector may comprise at least one filter element adapted to filter a narrow band of wavelength, such as a monochromator.

The illumination source may illuminate the object with a convergent and/or divergent and/or collimated light beam.

The illumination source and the sensor element may be arranged in a common plane or in different planes. The illumination source and the optical sensors may have different spatial orientation. In particular, the illumination source and the optical sensors may be arranged in a twisted arrangement.

In typical setups, commercially available quadrant diodes such as quadrant photodiodes are used for positioning, i.e. for adjusting and/or measuring a transversal coordinate of a light spot in the plane of the quadrant photodiode. Thus, as an example, laser beam positioning by using quadrant photodiodes is well known. According to a typical prejudice, however, quadrant photodiodes are used for xy-positioning, only. According to this assumption, quadrant photodiodes are not suitable for measuring distances. The above-mentioned findings, however, using an off-

centered quadrant photodiode with regard to an optical axis of the detector, show otherwise, as will be shown in further measurements below. Thus, as indicated above, in quadrant photodiodes, the asymmetry of the spot can be measured by shifting the quadrant diode slightly off-axis, such as by the above-mentioned offset. Thereby, a monotonously z-dependent function may be generated, such as by forming the quotient signal Q of two or more of the sensor signals of two or more partial photodiodes, i.e. quadrants, of the quadrant photodiode. Therein, in principle, only two photodiodes are necessary for the measurement. The other two diodes may be used for noise cancellation or to obtain a more precise measurement.

In addition or as an alternative to using a quadrant diode or quadrant photodiode, other types of optical sensors may be used. Thus, as will be shown in further detail below, staggered optical sensors may be used.

The use of quadrant diodes provides a large number of advantages over known optical detectors. Thus, quadrant diodes are used in a large number of applications in combination with LEDs or active targets and are widely commercially available at very low price, with various optical properties such as spectral sensitivities and in various sizes. No specific manufacturing process has to be established, since commercially available products may be implemented into the detector according to the present invention.

The detector according to the present invention specifically may be used in multilayer optical storage discs, such as disclosed by international patent application number PCT/IB2015/052233, filed on March 26, 2015. Measurements performed by using the detector according to the present invention specifically may be used in order to optimize the focus position in optical storage discs.

As will be outlined in further detail below, the distance measurement by using the detector according to the present invention may be enhanced by implementing one or more additional distance measurement means into the detector and/or by combining the detector with other types of distance measurement means. Thus, as an example, the detector may comprise or may be combined with at least one triangulation distance measurement device. Thus, the distance measurement can be enhanced by making use of a combination of the measurement principle discussed above and a triangulation type distance measurement. Further, means for measuring one or more other coordinates, such as x- and/or y-coordinates, may be provided.

In case a quadrant diode is used, the quadrant diode may also be used for additional purposes. Thus, the quadrant diode may also be used for conventional x-y-measurements of a light spot, as generally known in the art of optoelectronics and laser physics. Thus, as an example, the lens or detector position can be adjusted using the conventional xy-position information of the quadrant diode to optimize the position of the spot for the distance measurement. As a practical example, the light spot, initially, may be located right in the center of the quadrant diode, which typically does not allow for the above-mentioned distance measurement using the quotient function Q. Thus, firstly, conventional quadrant photodiode techniques may be used for off-centering

a position of the light spot on the quadrant photodiode, such that, e.g., the spot position on the quadrant diode is optimal for the measurement. Thus, as an example, the different off-centering of the optical sensors of the detector may simply be a starting point for movement of the optical sensors relative to the optical axis such that the light spot is off-centered with respect to the optical axis and with respect to a geometrical center of the array of the optical sensors.

Thus, generally, the optical sensors of the detector may form a sensor array or may be part of a sensor array, such as the above-mentioned quadrant diode. Thus, as an example, the detector may comprise an array of optical sensors, such as a rectangular array, having m rows and n columns, with m , n , independently, being positive integers. Preferably, more than one column and more than one row is given, i.e. $n > 1$, $m > 1$. Thus, as an example, n may be 2 to 16 or higher and m may be 2 to 16 or higher. Preferably, the ratio of the number of rows and the number of columns is close to 1. As an example, n and m may be selected such that $0.3 \leq m/n \leq 3$, such as by choosing $m/n = 1:1$, $4:3$, $16:9$ or similar. As an example, the array may be a square array, having an equal number of rows and columns, such as by choosing $m=2$, $n=2$ or $m=3$, $n=3$ or the like. The case $m=2$, $n=2$ is the case of the quadrant diode or quadrant optical sensor, which, for practical reasons, is one of the preferred cases, since quadrant photodiodes are widely available.

Thus, generally, the optical sensors of the detector may form a sensor array or may be part of a sensor array, such as the above-mentioned quadrant diode. Thus, as an example, the detector may comprise an array of optical sensors, such as a rectangular array, having m rows and n columns, with m , n , independently, being positive integers. Preferably, more than one column and more than one row is given, i.e. $n > 1$, $m > 1$. Thus, as an example, n may be 2 to 16 or higher and m may be 2 to 16 or higher. Preferably, the ratio of the number of rows and the number of columns is close to 1. As an example, n and m may be selected such that $0.3 \leq m/n \leq 3$, such as by choosing $m/n = 1:1$, $4:3$, $16:9$ or similar. As an example, the array may be a square array, having an equal number of rows and columns, such as by choosing $m=2$, $n=2$ or $m=3$, $n=3$ or the like. The case $m=2$, $n=2$ is the case of the quadrant diode or quadrant optical sensor, which, for practical reasons, is one of the preferred cases, since quadrant photodiodes are widely available.

As a starting point, a geometrical center of the optical sensors within the array may be off-centered from the optical axis, such as by the above-mentioned offset. The sensor array specifically may be movable relative to the optical axis, for example along a gradient, preferably automatically, such as by moving the sensor array, e.g. in a plane perpendicular to the optical axis, and/or by moving the optical axis itself, e.g. shifting the optical axis in a parallel shift and/or tilting the optical axis. Thus, the sensor array may be shifted in order to adjust a position of a light spot generated by the light beam in the plane of the sensor array. Additionally or alternatively, the optical axis may be shifted and/or tilted by using appropriate elements, such as by using one or more deflection elements and/or one or more lenses. The movement, as an example, may take place by using one or more appropriate actuators, such as one or more piezo actuators and/or one or more electromagnetic actuators and/or one or more pneumatic or me-

chanical actuators, which, e.g., move and/or shift the array and/or move and/or shift and/or tilt one or more optical elements in the beam path in order to move the optical axis, such as parallel shifting the optical axis and/or tilting the optical axis. The evaluation device specifically may be adjusted to control a relative position of the sensor array to the optical axis, e.g. in the plane perpendicular to the optical axis. An adjustment procedure may take place in that the evaluation device is configured for, firstly, determining the at least one transversal position of a light spot generated by the light beam on the sensor array by using the sensor signals and for, secondly, moving the array relative to the optical axis, such as by moving the array and/or the optical axis, e.g. by moving the array in the plane to the optical axis until the light spot is off-centered and/or by tilting a lens until the light spot is off-centered. As used therein, a transversal position may be a position in a plane perpendicular to the optical axis, which may also be referred to as the x-y-plane. For the measurement of the transversal coordinate, as an example, the sensor signals of the optical sensors may be compared. As an example, in case the sensor signals are found to be equal and, thus, in case it is determined that the light spot is located symmetrically with respect to the optical sensors, such as in the center of the quadrant diodes, a shifting of the array and/or a tilting of a lens may take place, in order to off-center the light spot in the array. Thus, as outlined above, the off-centering of the array from the optical axis, such as by off-centering the center of the quadrant photodiode from the optical axis, may simply be a starting point in order to avoid the situation which is typical, in which the light spot is located on the optical axis and, thus, is centered. By off-centering the array relative to the optical axis, thus, the light spot should be off-centered. In case this is found not to be true, such that the light spot, incidentally, is located in the center of the array and equally illuminates all optical sensors, the above-mentioned shifting of the array relative to the optical axis may take place, preferably automatically, in order to off-center the light spot on the array. Thereby, a reliable distance measurement may take place.

Further, in a scanning system with a movable light source, the position of the light spot on the quadrant diode may not be fixed. This is still possible, but may necessitate that different calibrations are used, dependent on the xy-position of the spot in the diode.

Further, the use of the above-mentioned quotient signal Q is a very reliable method for distance measurements. Typically, Q is a monotonous function of the longitudinal coordinate of the object and/or of the size of the light spot such as the diameter or equivalent diameter of the light spot. Thus, as an example, specifically in case linear optical sensors are used, the quotient $Q = s_1/s_2$ is a monotonously decreasing function of the size of the light spot. Without wishing to be bound by this theory, it is believed that this is due to the fact that, in the preferred setup described above, the sensor signals, such as the above-mentioned first sensor signal s_1 and the above-mentioned second sensor signal s_2 , decrease as a square function with increasing distance to the light source, since the amount of light reaching the detector decreases. Therein, however, due to the off-centering, the one of the sensor signals decreases more rapidly than the other, since, in the optical setup as used in the experiments, the light spot in the image plane grows and, thus, is spread over a larger area. By spreading the light spot, however, the portion of the light illuminating the one or more optical sensors outside the center of the light

spot increases, as compared to a situation of a very small light spot. Thus, the quotient of the sensor signals continuously changes, i.e. increases or decreases, with increasing diameter of the light beam or diameter of the light spot. The quotient, further, may further be rendered mainly independent from the total power of the light beam, since the total power of the light beam forms a factor in all sensor signals. Consequently, the quotient Q may form a secondary signal which provides a unique and unambiguous relationship between the sensor signals and the size or diameter of the light beam.

Since, on the other hand, the size or diameter of the light beam is dependent on a distance between the object, from which the light beam propagates towards the detector, and the detector itself, i.e. dependent on the longitudinal coordinate of the object, a unique and unambiguous relationship between the first and second sensor signals and the longitudinal coordinate may exist. For the latter, reference e.g. may be made to one or more of the above-mentioned prior art documents, such as WO 2014/097181 A1. The predetermined relationship may be determined by analytical considerations, such as by assuming a linear combination of Gaussian light beams, by empirical measurements, such as measurements measuring the first and second sensor signals or a secondary signal derived thereof as a function of the longitudinal coordinate of the object, or both.

Thus, generally, the evaluation device may be configured for determining the longitudinal coordinate by evaluating the quotient signal Q. The evaluation device may be configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate. The predetermined relationship may be one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship. The evaluation device may comprise at least one data storage device for storing the predetermined relationship, such as a lookup list or a lookup table.

The quotient signal Q may be determined by using various means. As an example, a software means for deriving the quotient signal, a hardware means for deriving the quotient signal, or both, may be used and may be implemented in the evaluation device. Thus, the evaluation device, as an example, may comprise at least one divider, wherein the divider is configured for deriving the quotient signal. The divider may fully or partially be embodied as one or both of a software divider or a hardware divider.

In view of the technical challenges involved in the prior art documents discussed above, specifically in view of the technical effort which is required for generating the FiP effect, it has to be noted that the present invention specifically may be realized by using non-FiP optical sensors. In fact, since optical sensors having the FiP characteristic typically exhibit a strong peak in the respective sensor signals at a focal point, the range of measurement of a detector according to the present invention using FiP sensors as optical sensors may be limited to a range in between the two positions and which the optical sensors are in focus of the light beam. When using linear optical sensors, however, i.e. optical sensors not exhibiting the FiP effect, this problem, with the setup of the present invention, generally may be avoided. Consequently, the optical sensors

may each have, at least within a range of measurement, a linear signal characteristic such that the respective first and second sensor signals may be dependent on the total power of illumination of the respective optical sensor and may be independent from a diameter of a light spot of the illumination. It shall be noted, however, that other embodiments are feasible, too.

5

The optical sensors each specifically may be semiconductor sensors, preferably inorganic semiconductor sensors, more preferably photodiodes and most preferably silicon photodiodes. Thus, as opposed to complex and expensive FiP sensors, the present invention simply may be realized by using commercially available inorganic photodiodes, i.e. one small photodiode and
10 one large area photodiode. Thus, the setup of the present invention may be realized in a cheap and inexpensive fashion.

In one embodiment, the detector may comprise at least one FiP sensor adapted for generating the so called FiP effect as described in WO 2015/024871 or WO2016/120392. For example, the
15 bi-cell or quadrant diode may be adapted to generate a so called FiP signal. As outlined e.g. in WO 2015/024871 or WO2016/120392, the FiP signal can be used to determine depth information over a wide distance range. The FiP sensor may be adapted to exhibit a positive and/or a negative FiP effect. According to the FiP-effect, the longitudinal sensor signal, given the same total power, may exhibit at least one pronounced maximum for one or a plurality of focusings
20 and/or for one or a plurality of specific sizes of the light spot on the sensor region or within the sensor region. For purposes of comparison, an observation of a maximum of the longitudinal sensor signal in a condition in which the corresponding material is impinged by a light beam with the smallest possible cross-section, such as when the material may be located at or near a focal point as affected by an optical lens, may be denominated as a "positive FiP-effect". The
25 negative FiP effect describes an observation of a minimum of the longitudinal sensor signal under a condition in which the corresponding material is impinged by a light beam with the smallest available beam cross-section, in particular, when the material may be located at or near a focal point as effected by an optical lens. The negative FiP effect may be used to tune small image effects at high distances. Image changes such as position, size, shape, sharpness, etc.
30 may vanish at high distances while the negative FiP effect increases. Furthermore, no luminance dependence may be introduced since both cells are at the same longitudinal position and thus receive identical photon density.

At least one of the optical sensors may be adapted to generate at least one sensor signal dependent on a time-of-flight (TOF) the illumination light beam has traveled from the illumination
35 source to the object and the reflection light beam has traveled from the object to the light sensitive area of the optical sensor. The evaluation device may be configured for determining at least one TOF-longitudinal coordinate z_{TOF} of the object by evaluating the TOF sensor signal. The optical sensor adapted to generate the TOF sensor signal may be designed as time-of-flight
40 detector. The time-of-flight detector may be selected from the group consisting of: at least one pulsed time-of-flight detector; at least one phase modulated time-of-flight detector; at least one direct time-of-flight detector; at least one indirect time-of-flight detector. For example, the pulsed time-of-flight detector may be at least one range gated imager and/or at least one direct time-of-

flight imager. For example the phase modulated time-of-flight detector may be at least one RF-modulated light source with at least one phase detector. The optical sensor may be adapted to determine a time delay between emission of the illumination light beam by the illumination source and receipt of the reflection light beam.

5

For example, the optical sensor adapted to generate the TOF sensor signal may be designed as pulsed time-of-flight detector. The detector may comprise the at least one interruption device, such as at least one shutter element, adapted to generate a pulsed light beam. The optical sensor may be adapted to store the TOF sensor signal dependent on the receiving time of the reflection light beam in a plurality of time windows, in particular subsequent time windows. The optical sensor may be adapted to store dependent on receiving time of the reflection light beam the generated TOF sensor signal in at least one first time window and/or in at least one second time window. The first and second time windows may be correlated with the opening and closure of the interruption device. Duration of first and second time windows may be pre-defined.

10

For example, the TOF sensor signal may be stored in the first time window during opening of the interruption device, whereas during closure of the interruption device the TOF sensor signal may be stored in the second time window. Other durations of time windows are thinkable. The first and the second time window may comprise information about background, signal height and signal shift.

15

20

For example, the optical sensor adapted to generate the TOF sensor signal may be designed as direct time-of-flight imager. The direct time-of-flight imager may comprise the at least one illumination source adapted to generate at least one single laser pulse. The single laser pulse may be reflected back from the object onto the optical sensor. The optical sensor may comprise at least one photodiode, for example at least one Avalanche Photo Diode (APD), such as at least one Si APD, or such as at least one InGaAs APD, or at least one PIN photo detector array, or at least one Single-Photon Avalanche Photodiode (SPAD), adapted to image the reflection light beam. The direct time-of flight imager may be adapted to image at least one image comprising spatial and temporal data.

25

30

For example, the optical sensor adapted to generate the TOF sensor signal may be designed as phase modulated time-of-flight modulator. The phase modulated time-of-flight modulator may be adapted to measure a difference in phase, in particular a phase shift, by determining a correlated signal, for example by multiplying a received signal, i.e. of the reflection light beam, with the emitted signal, i.e. the illumination light beam. A DC component of the correlated signal may comprise an information about the difference in phase. The evaluation device may be adapted to determine the second longitudinal coordinate of the object from the phase difference. For example, the illumination source and the optical sensor adapted to generate the TOF sensor signal may be designed as RF-modulated light source with at least one phase detector. The illumination source may comprise, for example, at least one LED and/or at least one laser. The illumination source may comprise at least one modulation device adapted to modulate the light beam having a pre-defined phase shift. For example, the modulation device may comprise at least one radio frequency module. The radio frequency module may be adapted to modulate the

35

40

illumination beam with an RF carrier. The optical sensor may be adapted to determine a phase shift of the reflective light beam impinging on the optical sensor.

The optical sensor may be designed as and/or may comprise at least one time-of-flight pixel.

5 Preferably, the detector may comprise at least two optical sensors, wherein each optical sensor is designed as and/or comprises at least one TOF pixel. For example, the detector, in particular the optical sensor may comprise a quadrant diode adapted to generate the TOF sensor signal. For example, the detector, in particular the optical sensor, may comprise at least one pixelated TOF-imager.

10 The evaluation device may be configured for determining the at least one TOF longitudinal coordinate z_{TOF} of the object by evaluating the TOF sensor signal. As used herein, the term "TOF longitudinal coordinate" refers to a longitudinal coordinate derived from the TOF sensor signal. As described above, the illumination light source may be adapted to periodically generate at least one light pulse. The detector may be adapted to generate the first longitudinal sensor signal for each period. The evaluation device may be adapted to determine in which pulse period the TOF sensor signal was generated using the second longitudinal coordinate. The detector may be adapted to uniquely assign to which period the ToF-signal refers to by using the combined sensor signal. Both, the TOF sensor signal and the combined sensor signal, may be non-monotonous functions of the longitudinal coordinate z_{real} . Thus, the longitudinal coordinate may not be uniquely determined from one of the TOF sensor signal or the combined sensor signal alone and a measurement range may not be restricted to a longitudinal range in which the signals are unique functions of z_{real} . The term "measurement range" generally refers to a range from the object to the detector in which determination of the longitudinal coordinate is possible.

25 The term "longitudinal range" generally refers to a range from the object to the detector in which unique determination of the longitudinal coordinate is possible. Below and/or above certain distances from the object to the detector a determination of the longitudinal coordinate may not be possible. For example, time-of-flight measurements are not possible below a certain distance from the object to the detector, possibly due to the minimum measurement time of the internal clock. Furthermore, in time-of-flight measurements the sensor signal may be unique within a longitudinal period, but the sensor signal may be the same in case integer multiples of the longitudinal period are added such that the determined longitudinal coordinate may be non-unique. Thus, the same TOF sensor signal will be obtained for a distance z_1 and a distance $z_1 + n \cdot z_{1p}$, where n is an integer denoting the longitudinal period and z_{1p} is the longitudinal period of the TOF sensor signal, wherein the distances z_1 and $z_1 + n \cdot z_{1p}$ are within the measurement range. As used herein, the term "longitudinal period" refers to partitions of a period, in particular a distance range, in which the longitudinal coordinate can be unambiguously determined from the TOF sensor signal. Non-unique longitudinal coordinates may be denoted as relative longitudinal coordinates and the unique longitudinal coordinates may be denoted as absolute longitudinal coordinates.

If both the TOF sensor signal $F1$ and the combined sensor signals $F2$ are available, it may be possible to uniquely determine the longitudinal coordinate and to extend the longitudinal range,

as long as each signal pair (F1,F2) corresponds to a unique distance and vice versa. In particular, if a unique signal pair (F1,F2) exists for each longitudinal coordinate and vice versa, the evaluation device may be adapted to determine the unique combined longitudinal coordinate by

(1) selecting at least one first selected signal such as the TOF sensor signal and/or the combined sensor signal and determining non-unique first longitudinal coordinates;

(2) selecting a second selected signal such as the combined signal Q and/or the TOF sensor signal, which was not selected in step (1), and determining non-unique second longitudinal coordinates;

(3) determining whether one of the non-unique first longitudinal coordinates and the non-unique second longitudinal coordinates match up to a predetermined tolerance threshold;

(4) setting a combined unique longitudinal coordinate to be a matching longitudinal coordinate.

In step (1) and step (2), signals may be selected in the given order or may be performed in a different order. For example, in step (1) the TOF sensor signal may be selected and in step (2) the combined signal Q may be selected. In another example, in step (1) the combined sensor signal may be selected, and the non-unique first longitudinal sensor signal may be determined therefrom. In step (2), the TOF sensor signal may be selected.

Additionally or alternatively to step (4), the evaluation device may be adapted to output an error signal in case no matching coordinates are found and/or to output an error signal in case more than one matching coordinates are found. Additionally or alternatively, the signal pairs and their corresponding longitudinal coordinates may be stored in a look-up table. Additionally or alternatively, the signal pairs and their corresponding longitudinal coordinates may be approximated or described by an analytical function which is evaluated to find the longitudinal coordinate corresponding to a given signal pair.

The evaluation device may comprise at least two memory elements. As used herein, the term "memory element" refers to a device adapted to store information. The evaluation device may be adapted to receive and to store information provided by the optical sensors, for example the at least one first sensor signal. Such information may comprise raw sensor data and/or processed sensor data. For example, the memory element may be adapted to store information for further evaluation by the evaluation device. The memory element may be a volatile or non-volatile memory element.

As described above, the optical sensor may be designed as and/or may comprise at least one ToF pixel. The detector may comprise at least two switches. Each of the switches may be connected to the optical sensor adapted to generate the first sensor signal, for example by at least one connector. In particular, each of the switches may be connected to the ToF pixel. The switches are adapted to provide the TOF sensor signal to one of the memory elements. In particular, the switches may be adapted to let, dependent on receiving time of the reflection light beam, the generated TOF sensor signal pass through one of the switches. For example, the TOF sensor signal may pass one of the switches during opening of the interruption device, whereas during closure of the interruption device the TOF sensor signal may pass the other

switch. Each of the switches may be controlled by a control signal having a pulse length identical to a pulse length of a light pulse generated by the illumination source. The control signal of one of the switches may be delayed. For example, the delay may correspond to the pulse length of the light pulse. The evaluation device may be adapted to sample and/or store depending on the delay a first part, or fraction, of the TOF sensor signal through a first switch in a first memory element and the other, second part, or fraction, of the TOF sensor signal through a second switch in a second memory element. The evaluation device may be adapted to determine the first longitudinal coordinate by evaluating the first part and second part of the TOF sensor signal. The evaluation device may be adapted to determine the first longitudinal coordinate z_1 by

$$z_1 = \frac{1}{2} \cdot c \cdot t_0 \cdot \frac{S_{12}}{S_{11} + S_{12}} + z_0;$$

wherein c is the speed of light, t_0 is the pulse length of the illumination light beam, z_0 is a distance offset often determined by the resolution of the time measurement, and S_{11} and S_{12} are the first part and second part of the TOF sensor signal, respectively.

As outlined above, the detector may further comprise one or more additional elements such as one or more additional optical elements. Further, the detector may fully or partially be integrated into at least one housing.

As outlined above, specifically, quadrant photodiodes may be used. As an example, commercially available quadrant photodiodes may be integrated in order to provide four optical sensors, such as one or more quadrant photodiodes available from Hamamatsu Photonics Deutschland GmbH, D-82211 Herrsching am Ammersee, Germany, such as quadrant Si PIN photodiodes of the type S4349, which are sensitive in the UV spectral range to the near IR spectral range. In case an array of optical sensors is used, the array may be a naked chip or may be an encapsulated array, such as encapsulated in a TO-5 metal package. Additionally or alternatively, a surface mounted device may be used, such as TT Electronics OPR5911 available from TT Electronics plc, Fourth Floor, St Andrews House, West Street Woking Surrey, GU21 6EB, England. It shall be noted that other optical sensors may also be used.

Further, it shall be noted that, besides the option of using precisely one quadrant photodiode, two or more quadrant photodiodes may also be used. Thus, as an example, a first quadrant photodiode may be used for the distance measurement, as described above, providing the two or more optical sensors. Another quadrant photodiode may be used, e.g. in a second partial beam path split off from the beam path of the first quadrant photodiode, for a transversal position measurement, such as for using at least one transversal coordinate x and/or y . The second quadrant photodiode, as an example, may be located on-axis with respect to the optical axis.

Further, it shall be noted that, besides the option of using one or more quadrant photodiodes, one or more quadrant photodiodes or further photodiode arrays may also be replaced or mimicked by separated photodiodes that are arranged or assembled close to each other, preferably in a symmetric shape such as a rectangular matrix, such as a 2×2 matrix. However further arrangements are feasible. In such an arrangement or assembly, the photodiodes may be ar-

5 ranged or assembled in a housing or mount, such as all photodiodes in a single housing or mount or groups of photodiodes in one housing or mount, or each of the photodiodes in a separate housing or mount. Further, the photodiodes may also be assembled directly on a circuit board. In such arrangements or assemblies, photodiodes may be arranged as such that the separation between the active area of the photodiodes, has a distinct value less than one centimeter, preferably less than one millimeter, more preferably as small as possible. Further, to avoid optical reflexes, distortions, or the like that may deteriorate the measurement, the space between the active areas may be either empty or filled with a material, preferably with a light absorbing material such as a black polymer, such as black silicon, black polyoxymethylene, or the like, more preferably optically absorbing and electrically insulating material, such as black ceramics or insulating black polymers such as black silicon, or the like. Further, the distinct value of the photodiode separation may also be realized by adding a distinct building block between the photodiodes such as a plastic separator. Further embodiments are feasible. The replacement of quadrant photodiodes by single diodes arranged in a similar setup such as in a 2 x 2 rectangular matrix with minimal distance between the active areas may further minimize the costs for the optical detector. Further, two or more diodes from a quadrant diode may be connected in parallel or in series to form a single light sensitive area.

20 Additionally or alternatively, the optical sensors may comprise at least one optical sensor of an intrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge photodiode, an InGaAs photodiode, an extended InGaAs photodiode, an InAs photodiode, an InSb photodiode, a HgCdTe photodiode. Additionally or alternatively, the optical sensors may comprise at least one optical sensor of an extrinsic photovoltaic type, more preferably at least one semiconductor photodiode selected from the group consisting of: a Ge:Cu photodiode, a Ge:Zn photodiode, a Si:Ga photodiode, a Si:As photodiode. Additionally or alternatively, the optical sensors may comprise at least one bolometer, preferably a bolometer selected from the group consisting of a VO bolometer and an amorphous Si bolometer. The optical sensors may comprise differing materials or photovoltaic concepts. As an example, at least one first optical sensor may be a Ge photodiode, whereas at least one second optical sensor may be an InGaAs photodiode. As a further example, the first and second optical sensor may comprise the same material with a differing doping such as a differing doping concentration or doping material.

35 The optical sensors each, independently, may be opaque, transparent or semitransparent. For the sake of simplicity, however, opaque sensors which are not transparent for the light beam, may be used, since these opaque sensors generally are widely commercially available.

The optical sensors each specifically may be uniform sensors having a single light-sensitive area each. Thus, the optical sensors specifically may be non-pixelated optical sensors.

40 The detector may further comprise an illumination source for illuminating the object. As an example, the illumination source may be configured for generating an illuminating light beam for illuminating the object. The detector may be configured such that the illuminating light beam

propagates from the detector towards the object along an optical axis of the detector. For this purpose, the detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis. Specifically, the illumination source may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. The illumination source may be adapted to generate and/or to project a cloud of points, for example the illumination source may comprise one or more of at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources.

The illuminating light beam generally may be parallel to the optical axis or tilted with respect to the optical axis, e.g. including an angle with the optical axis. As an example, the illuminating light beam, such as the laser light beam, and the optical axis may include an angle of less than 10° , preferably less than 5° or even less than 2° . Other embodiments, however, are feasible. Further, the illuminating light beam may be on the optical axis or off the optical axis. As an example, the illuminating light beam may be parallel to the optical axis having a distance of less than 10 mm to the optical axis, preferably less than 5 mm to the optical axis or even less than 1 mm to the optical axis or may even coincide with the optical axis.

The detector may comprise the at least one illumination source. The illumination source may be adapted to illuminate the object with at least one illumination light beam. The illumination light beam may be fully or partially reflected by the object and may travel back towards the detector. The illumination source may be arranged such that a direction of propagation of the illumination light beam is essentially parallel to the optical axis. As used herein, the term "essentially parallel to the optical axis" refers to the condition of a parallel orientation, with a tolerance of e.g. $\pm 20^\circ$ or less, preferably a tolerance of $\pm 10^\circ$ or less, more preferably a tolerance of $\pm 5^\circ$ or less. The illumination source may be arranged such that a line running in the direction of propagation of the illumination light beam and the optical axis do not intersect in space. In particular, the illumination may be on-axis. In order to provide such an on-axis illumination, as an example, one or more reflective elements may be used, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms. The reflected light beam may be essentially parallel to the optical axis. Thus, according to the present invention, the object distance is not determined from an angle of the light beam, i.e. a position of the light spot on a sensor, as done in triangulation methods. Instead, the object distance may be determined using light beams essential parallel to the optical axis. Determination of the object distance by a non-triangulation method but by combining the at least two sensor signals, allows arranging the illumination source such that the direction of propagation of the illumination light beam is essentially parallel to the optical axis.

The illumination source and the optical axis may be separated by a small baseline. As used herein, the term "baseline", also denoted as basis line, refers to a distance, for example in a xy-plane, between the optical axis and the illumination source, in particular a distance between the

optical axis and a z-component of the illumination light beam. The illumination source may be spaced apart from the optical axis by a minimum distance. The minimum distance from the optical axis may be defined by further detector elements such as size and position of the optical sensors and transfer device. The baseline may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. For example, the baseline may be 21 mm. Preferably, the illumination source may be arranged right next to the transfer device. For example, the transfer device may be flattened such that the illumination source can be positioned even closer to the optical axis. The illumination source may be arranged behind the transfer device. Triangulation systems require a sufficient baseline, however due to the baseline in the near field no detection may be possible. Near field detection may be possible if the light spot is tilted in direction of the transfer device. However, the tilting leads to that the light spot will move out of the field of view which limits detection in far field regions. Thus, in triangulation systems, the non-zero baseline will always lead to a substantial reduction in the measurement range, in the near field, and/or in the far field. Reducing the baseline as possible with the detector according to the present invention will thus always increase the measurement range. For example, the detector may be a compact device without further optical elements, wherein the illumination source may be placed as close as possible to an edge of the transfer device. Thus, the baseline may be close to half a diameter of the transfer device, in particular the lens diameter and housings of lens and light source. For example, the detector may be an even more compact device, wherein a mirror, in particular a small mirror, may be positioned in front of the transfer device, in particular in a center, for example a geometrical center, or close to the center of the transfer device, in order to couple the illumination beam into the beam path. Thus, the baseline may be less than half the diameter of the transfer device. The illumination source may be arranged such that the baseline is as small as possible. By arranging the illumination source such that the direction of propagation of the illumination light beam is essentially parallel to the optical axis and that the illumination source and the optical axis are separated by the small baseline, very compact devices are possible. For example, a distance from the center of the transfer device to the illumination source, in particular along a connecting line from the center of the transfer device to the illumination source, may be preferably less than 2.5 times a distance from the center of the transfer device to an edge of the transfer device, more preferably less than 1.5 times the distance center to edge of the transfer device, and most preferably less 1 times the distance center to edge of the transfer device. The transfer device may have an arbitrary shape, in particular a non-circular shapes are possible. At small distances an aperture of the illumination source may be small and the baseline may be small. At large distances an aperture of the illumination source may be large and the baseline may be small. This is contrarily as in triangulation methods, wherein at large distances a large baseline is necessary. Further, triangulation based systems have a minimum detection range significantly greater than zero, for example such as 20 cm from the detector system, due to necessary spatial extend of the baseline. Such a large baseline may result in that the illuminated light scattered from the object may not reach the light sensitive area of the optical sensor behind the transfer device. In addition, in triangulation based systems, using a small baseline would reduce the minimum detection range, however, at the same time would reduce a maximum detection range. Further, triangulation based systems require a plurality of light sensitive areas and sensor signals, for example sensor signals of at least one detector row.

According to the invention, determination of the longitudinal coordinate z is possible with a reduced number of sensor signals, in particular with less than 20, preferably less than 10 and more preferably less than 5 sensor signals.

5 The illumination source may be adapted to generate at least one illumination pattern for illuminating the object. Additionally or alternatively, the illumination pattern may be generated by at least one ambient light source. The detector may be configured such that the illumination pattern propagates from the detector, in particular from at least one opening of the housing, towards the object along and/or parallel to an optical axis of the detector. For this purpose, the
10 detector may comprise at least one reflective element, preferably at least one prism, for deflecting the illumination pattern such that it propagates along or parallel to the optical axis. Specifically, the illumination source may comprise at least one laser and/or laser source. Various types of lasers may be employed, such as semiconductor lasers. Additionally or alternatively, non-laser light sources may be used, such as LEDs and/or light bulbs. As used herein, the term "pattern"
15 refers to an arbitrary known or pre-determined arrangement comprising at least one arbitrarily shaped feature. The pattern may comprise at least one feature such as a point or symbol. The pattern may comprise a plurality of features. The pattern may comprise an arrangement of periodic or non-periodic features. As used herein, the term "illumination pattern" refers to a pattern which illuminates the object. The illumination pattern may be generated by ambient light,
20 such as by at least one ambient light source, or by the at least one illumination source. The illumination pattern may comprise at least one pattern selected from the group consisting of: at least one point pattern, at least one pattern comprising at least one pre-known feature; at least one regular pattern; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines.

25 The illumination source may comprise one or more of at least one light projector; at least one digital light processing (DLP) projector, at least one LCoS projector, at least one spatial light modulator; at least one diffractive optical element; at least one array of light emitting diodes; at least one array of laser light sources. The illumination source may comprise at least one light
30 source adapted to generate the illumination pattern directly. For example, the illumination source may comprise at least one laser source. For example, the illumination source may comprise at least one line laser. The line laser may be adapted to send a laser line to the object, for example a horizontal or vertical laser line. The illumination source may comprise a plurality of line lasers. For example, the illumination source may comprise at least two line lasers which
35 may be arranged such that the illumination pattern comprises at least two parallel or crossing lines. The illumination source may comprise the at least one light projector adapted to generate at least one point, e.g. a cloud of points such that the illumination pattern may comprise a plurality of point pattern. The illumination source may comprise at least one mask adapted to generate the illumination pattern from at least one light beam generated by the illumination source.

40 The illumination source may be one of attached to or integrated into a mobile device such as a smartphone. The illumination source may be used for further functions that may be used in determining an image such as for an autofocus function. The illumination source may be attached

to a mobile device such as by using a connector such as a USB- or phone-connector such as the headphone jack.

5 The illumination source may be adapted to generate pulsed illumination. The illumination source may be adapted to generate at least one light pulse. As used herein, the term “light pulse” or “pulsed illumination” refers to a light beam limited in time. The light pulse may have a pre-defined length or time duration, for example in the nanoseconds range. For example, the illumination source may be adapted to generate pulses with a pulse length of less than a nanosecond, such as a tenth of a nanosecond, up to a tenth of a second. The illumination source may
10 be adapted to periodically generate the light pulse. For example, the illumination source may be adapted to generate the light pulse with a frequency of 10 Hz to 10 GHz.

The illumination source may be adapted to generate a pulsed light beam. For example, the illumination source may be adapted to generate a continuous illumination light beam and the detector
15 may comprise at least one interruption device adapted to interrupt the illumination, in particular periodically. The interruption device may comprise at least one shutter and/or a beam chopper or some other type of mechanical or electronical periodic beam interrupting device, for example comprising at least one interrupter blade or interrupter wheel, which preferably rotates at constant speed and which can thus periodically interrupt the illumination. By way of example,
20 the at least one interruption device can also be wholly or partly integrated into the illumination source. Various possibilities are conceivable.

The detector may further comprise at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensors. The transfer device specifically may
25 comprise one or more of: at least one lens, preferably at least one focus-tunable lens; at least one beam deflection element, preferably at least one mirror; at least one diffractive optical element; at least one Fresnel lens; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

30 The optical sensors may be positioned off focus. As used herein, the term “focus” generally refers to one or both of a minimum extend of a circle of confusion of the light beam, in particular of at least one light beam emitted from one point of the object, caused by the transfer device or a focal length of the transfer device. As used herein, the term “circle of confusion” refers to a light spot caused by a cone of light rays of the light beam focused by the transfer device. The circle
35 of confusion may depend on a focal length f of the transfer device, a longitudinal distance from the object to the transfer device, a diameter of an exit pupil of the transfer device, a longitudinal distance from the transfer device to the light sensitive area, a distance from the transfer device to an image of the object. For example, for Gaussian beams, a diameter of the circle of confusion may be a width of the Gaussian beam. In particular, for a point like object situated or
40 placed at infinite distance from the detector the transfer device may be adapted to focus the light beam from the object into a focus point at the focal length of the transfer device. For non-point like objects situated or placed at infinite distance from the detector the transfer device may be adapted to focus the light beam from at least one point of the object into a focus plane at the

focal length of the transfer device. For point like objects not situated or placed at infinite distance from the detector, the circle of confusion may have a minimum extend at least at one longitudinal coordinate. For non-point like objects not situated or placed at infinite distance from the detector, the circle of confusion of the light beam from at least one point of the object may have a minimum extend at least at one longitudinal coordinate. As used herein, the term “positioned off focus” generally refers to a position other than the minimum extend of a circle of confusion of the light beam caused by the transfer device or a focal length of the transfer device. In particular, the focal point or minimum extend of the circle of confusion may be at a longitudinal coordinate l_{focus} , whereas the position of each of the optical sensors may have a longitudinal coordinate l_{sensor} different from l_{focus} . For example, the longitudinal coordinate l_{sensor} may be, in a longitudinal direction, arranged closer to the position of the transfer device than the longitudinal coordinate l_{focus} or may be arranged further away from the position of the transfer device than the longitudinal coordinate l_{focus} . Thus, the longitudinal coordinate l_{sensor} and the longitudinal coordinate l_{focus} may be situated at different distances from the transfer device. For example, the optical sensors may be spaced apart from the minimum extend of the circle of confusion in longitudinal direction by $\pm 2\%$ focal length, preferably by $\pm 10\%$ focal length, most preferably $\pm 20\%$ focal length. For example, at a focal length of the transfer device may be 20mm and the longitudinal coordinate l_{sensor} may be 19,5 mm, i.e. the sensors may be positioned at 97,5% focal length, such that l_{sensor} is spaced apart from the focus by 2,5% of focal length. The extent of the circle of confusion may be larger than the extent of the optical sensor. For example, the optical sensor may be positioned as such that the circle of confusion extends beyond the optical sensor. The optical sensor may thus only partially evaluate the beam profile of the light beam.

The above-mentioned operations, including determining the at least one longitudinal coordinate of the object, are performed by the at least one evaluation device. Thus, as an example, one or more of the above-mentioned relationships may be implemented in software and/or hardware, such as by implementing one or more lookup tables. Thus, as an example, the evaluation device may comprise one or more programmable devices such as one or more computers, application-specific integrated circuits (ASICs), Field Programmable Gate Arrays (FPGAs), or digital signal processors (DSPs) which are configured to perform the above-mentioned evaluation, in order to determine the at least one longitudinal coordinate of the object. Additionally or alternatively, however, the evaluation device may also fully or partially be embodied by hardware.

As outlined above, by evaluating the sensor signals, the detector may be enabled to determine the at least one longitudinal coordinate of the object, including the option of determining the longitudinal coordinate of the whole object or of one or more parts thereof. In addition, however, other coordinates of the object, including one or more transversal coordinates and/or rotational coordinates, may be determined by the detector, specifically by the evaluation device. Thus, as an example, one or more additional transversal sensors may be used for determining at least one transversal coordinate of the object. Various transversal sensors are generally known in the art, such as the transversal sensors disclosed in WO 2014/097181 A1 and/or other position-sensitive devices (PSDs), such as quadrant diodes, CCD or CMOS chips or the like. These devices may generally also be implemented into the detector according to the present invention.

As an example, a part of the light beam may be split off within the detector, by at least one beam splitting element. The split-off portion, as an example, may be guided towards a transversal sensor, such as a CCD or CMOS chip or a camera sensor, and a transversal position of a light spot generated by the split-off portion on the transversal sensor may be determined, thereby determining at least one transversal coordinate of the object. Consequently, the detector according to the present invention may either be a one-dimensional detector, such as a simple distance measurement device, or may be embodied as a two-dimensional detector or even as a three-dimensional detector. Further, as outlined above or as outlined in further detail below, by scanning a scenery or an environment in a one-dimensional fashion, a three-dimensional image may also be created. Consequently, the detector according to the present invention specifically may be one of a one-dimensional detector, a two-dimensional detector or a three-dimensional detector. The evaluation device may further be configured to determine at least one transversal coordinate x , y of the object. The evaluation device may be adapted to combine the information of the longitudinal coordinate and the transversal coordinate and to determine a position of the object in space.

As outlined above, the detector may further comprise one or more additional elements such as one or more additional optical elements. Further, the detector may fully or partially be integrated into at least one housing. The detector specifically may comprise at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensor. The transfer device may comprise one or more of: at least one lens, preferably at least one focus-tunable lens; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system. Further, if applicable, Fresnel lenses or diffractive optical elements may be used. Therein, generally, the term "transfer device" may generally refer to one or more optical elements which are adapted to modify the light beam, such as by modifying one or more of a beam parameter of the light beam, a width of the light beam or a direction of the light beam. The transfer device may be adapted to guide the light beam onto the optical sensors. The transfer device specifically may comprise one or more of: at least one lens, for example at least one lens selected from the group consisting of, preferably at least one focus-tunable lens, at least one aspheric lens, at least one spheric lens, at least one Fresnel lens; at least one diffractive optical element; at least one concave mirror; at least one beam deflection element, preferably at least one mirror; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

In a further aspect of the present invention, a detector system for determining a position of at least one object is disclosed. The detector system comprises at least one detector according to the present invention, such as according to one or more of the embodiments disclosed above or according to one or more of the embodiments disclosed in further detail below. The detector system further comprises at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object. Further details regarding the beacon device will be given below, including potential embodiments thereof. Thus, the at least one bea-

con device may be or may comprise at least one active beacon device, comprising one or more illumination sources such as one or more light sources like lasers, LEDs, light bulbs or the like. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. Additionally or alternatively, the at least one beacon device may be adapted to reflect one
5 or more light beams towards the detector, such as by comprising one or more reflective elements. Further, the at least one beacon device may be or may comprise one or more scattering elements adapted for scattering a light beam. Therein, elastic or inelastic scattering may be used. In case the at least one beacon device is adapted to reflect and/or scatter a primary light beam towards the detector, the beacon device may be adapted to leave the spectral properties
10 of the light beam unaffected or, alternatively, may be adapted to change the spectral properties of the light beam, such as by modifying a wavelength of the light beam.

In a further aspect of the present invention, a human-machine interface for exchanging at least one item of information between a user and a machine is disclosed. The human-machine inter-
15 face comprises at least one detector system according to the embodiments disclosed above and/or according to one or more of the embodiments disclosed in further detail below. Therein, the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user or held by the user. The human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface
20 is designed to assign to the position at least one item of information.

In a further aspect of the present invention, an entertainment device for carrying out at least one entertainment function is disclosed. The entertainment device comprises at least one human-
25 machine interface according to the embodiment disclosed above and/or according to one or more of the embodiments disclosed in further detail below. The entertainment device is configured to enable at least one item of information to be input by a player by means of the human-machine interface. The entertainment device is further configured to vary the entertainment function in accordance with the information.

In a further aspect of the present invention, a tracking system for tracking a position of at least one movable object is disclosed. The tracking system comprises at least one detector system according to one or more of the embodiments referring to a detector system as disclosed above and/or as disclosed in further detail below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at spe-
30 cific points in time.

In a further aspect of the present invention, a camera for imaging at least one object is disclosed. The camera comprises at least one detector according to any one of the embodiments referring to a detector as disclosed above or as disclosed in further detail below.

40 In a further aspect of the present invention, a readout device for optical storage media is proposed. The readout device comprises at least one detector according to any one of the preceding embodiments referring to a detector. As used therein, a readout device for optical storage

media generally refers to a device which is capable of optically retrieving information stored in optical storage media such as optical storage discs, e.g. CCD, DVD or Blu-ray discs. Thus, the above-described measurement principle of the detector according to the present invention may be used for detecting data modules within an optical storage medium such as in optical storage
5 discs. As an example, in case a reflective data module is present and reflects the illuminating light beam, the detector will not only detect the reflected light beam according to the above-mentioned measurement principle but will also detect a distance between the detector and the reflective data module, i.e. a depth of the reflective data module within the optical storage medium. Thus, as an example, the detector may be used for detecting different layers of information
10 modules or data modules within the optical storage medium. Thereby, as an example, two layer discs or three layer discs or even discs having more than three layers may be generated and read out.

In a further aspect of the present invention, a scanning system for determining a depth profile of a scenery, which may also imply determining at least one position of at least one object, is provided. The scanning system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The scanning system further comprises at least one illumination source adapted to scan the scenery with at least one light
20 beam, which may also be referred to as an illumination light beam or scanning light beam. As used herein, the term "scenery" generally refers to a two-dimensional or three-dimensional range which is visible by the detector, such that at least one geometric or spatial property of the two-dimensional or three-dimensional range may be evaluated with the detector. As further used herein, the term "scan" generally refers to a consecutive measurement in different regions. Thus, the scanning specifically may imply at least one first measurement with the illumination light beam being oriented or directed in a first fashion, and at least one second measurement with the illumination light beam being oriented or directed in a second fashion which is different from the first fashion. The scanning may be a continuous scanning or a stepwise scanning. Thus, in a continuous or stepwise fashion, the illumination light beam may be directed into different regions of the scenery, and the detector may be detected to generate at least one item of
30 information, such as at least one longitudinal coordinate, for each region. As an example, for scanning an object, one or more illumination light beams may, continuously or in a stepwise fashion, create light spots on the surface of the object, wherein longitudinal coordinates are generated for the light spots. Alternatively, however, a light pattern may be used for scanning. The scanning may be a point scanning or a line scanning or even a scanning with more complex light patterns. The illumination source of the scanning system may be distinct from the optional illumination source of the detector. Alternatively, however, the illumination source of the scanning system may also be fully or partially identical with or integrated into the at least one optional illumination source of the detector.

Thus, the scanning system may comprise at least one illumination source which is adapted to emit the at least one light beam being configured for the illumination of the at least one dot located at the at least one surface of the at least one object. As used herein, the term "dot" refers

to an area, specifically a small area, on a part of the surface of the object which may be selected, for example by a user of the scanning system, to be illuminated by the illumination source. Preferably, the dot may exhibit a size which may, on one hand, be as small as possible in order to allow the scanning system to determine a value for the distance between the illumination source comprised by the scanning system and the part of the surface of the object on which the dot may be located as exactly as possible and which, on the other hand, may be as large as possible in order to allow the user of the scanning system or the scanning system itself, in particular by an automatic procedure, to detect a presence of the dot on the related part of the surface of the object.

For this purpose, the illumination source may comprise an artificial illumination source, in particular at least one laser source and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. As an example, the light emitted by the illumination source may have a wavelength of 300-500 nm. On account of their generally defined beam profiles and other properties of handleability, the use of at least one laser source as the illumination source is particularly preferred. Herein, the use of a single laser source may be preferred, in particular in a case in which it may be important to provide a compact scanning system that might be easily storable and transportable by the user. The illumination source may thus, preferably be a constituent part of the detector and may, therefore, in particular be integrated into the detector, such as into the housing of the detector. In a preferred embodiment, particularly the housing of the scanning system may comprise at least one display configured for providing distance-related information to the user, such as in an easy-to-read manner. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least one button which may be configured for operating at least one function related to the scanning system, such as for setting one or more operation modes. In a further preferred embodiment, particularly the housing of the scanning system may, in addition, comprise at least one fastening unit which may be configured for fastening the scanning system to a further surface, such as a rubber foot, a base plate or a wall holder, such as a base plate or holder comprising a magnetic material, in particular for increasing the accuracy of the distance measurement and/or the handleability of the scanning system by the user.

Particularly, the illumination source of the scanning system may, thus, emit a single laser beam which may be configured for the illumination of a single dot located at the surface of the object. By using at least one of the detectors according to the present invention, at least one item of information about the distance between the at least one dot and the scanning system may, thus, be generated. Hereby, preferably, the distance between the illumination system as comprised by the scanning system and the single dot as generated by the illumination source may be determined, such as by employing the evaluation device as comprised by the at least one detector. However, the scanning system may, further, comprise an additional evaluation system which may, particularly, be adapted for this purpose. Alternatively or in addition, a size of the scanning system, in particular of the housing of the scanning system, may be taken into account and, thus, the distance between a specific point on the housing of the scanning system, such as

a front edge or a back edge of the housing, and the single dot may, alternatively, be determined.

Alternatively, the illumination source of the scanning system may emit two individual laser
5 beams which may be configured for providing a respective angle, such as a right angle, between the directions of an emission of the beams, whereby two respective dots located at the surface of the same object or at two different surfaces at two separate objects may be illuminated. However, other values for the respective angle between the two individual laser beams may also be feasible. This feature may, in particular, be employed for indirect measuring functions,
10 such as for deriving an indirect distance which may not be directly accessible, such as due to a presence of one or more obstacles between the scanning system and the dot or which may otherwise be hard to reach. By way of example, it may, thus, be feasible to determine a value for a height of an object by measuring two individual distances and deriving the height by using the Pythagoras formula. In particular for being able to keep a predefined level with respect to
15 the object, the scanning system may, further, comprise at least one leveling unit, in particular an integrated bubble vial, which may be used for keeping the predefined level by the user.

As a further alternative, the illumination source of the scanning system may emit a plurality of individual laser beams, such as an array of laser beams which may exhibit a respective pitch, in
20 particular a regular pitch, with respect to each other and which may be arranged in a manner in order to generate an array of dots located on the at least one surface of the at least one object. For this purpose, specially adapted optical elements, such as beam-splitting devices and mirrors, may be provided which may allow a generation of the described array of the laser beams. In particular, the illumination source may be directed to scan an area or a volume by using one
25 or more movable mirrors to redirect the light beam in a periodic or non-periodic fashion.

Thus, the scanning system may provide a static arrangement of the one or more dots placed on the one or more surfaces of the one or more objects. Alternatively, the illumination source of the scanning system, in particular the one or more laser beams, such as the above described array
30 of the laser beams, may be configured for providing one or more light beams which may exhibit a varying intensity over time and/or which may be subject to an alternating direction of emission in a passage of time, in particular by moving one or more mirrors, such as the micro-mirrors comprised within the mentioned array of micro-mirrors. As a result, the illumination source may be configured for scanning a part of the at least one surface of the at least one object as an im-
35 age by using one or more light beams with alternating features as generated by the at least one illumination source of the scanning device. In particular, the scanning system may, thus, use at least one row scan and/or line scan, such as to scan the one or more surfaces of the one or more objects sequentially or simultaneously. As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning
40 devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics

applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step. As non-limiting examples, the scanning system may be used in industrial safety curtain applications. As non-limiting examples, the scanning system may be used to perform sweeping, vacuuming, mopping, or waxing functions, or yard or garden care functions such as mowing or raking. As non-limiting examples, the scanning system may employ an LED illumination source with collimated optics and may be adapted to shift the frequency of the illumination source to a different frequency to obtain more accurate results and/or employ a filter to attenuate certain frequencies while transmitting others. As non-limiting examples, the scanning system and/or the illumination source may be rotated as a whole or rotating only a particular optics package such as a mirror, beam splitter or the like, using a dedicated motor as such that in operation, the scanning system may have a full 360 degree view or even be moved and or rotated out of plane to further increase the scanned area. Further, the illumination source may be actively aimed in a predetermined direction. Further, to allow the rotation of wired electrical systems, slip rings, optical data transmission, or inductive couplings may be employed.

As a non-limiting example, the scanning system may be attached to a tripod and point towards an object or region with a several corners and surfaces. One or more flexibly movable laser sources may be attached to the scanning system. The one or more laser sources may be moved as such that they illuminate points of interest. The position of the illuminated points with respect to the scanning system may be measured when pressing a designated button on the scanning system and the position information is transmitted via a wireless interface to a mobile phone. The position information may be stored in a mobile phone application. The laser sources may be moved to illuminate further points of interest the position of which are measured and transmitted to the mobile phone application. The mobile phone application may transform the set of points into a 3d model by connecting adjacent points with planar surfaces. The 3d model may be stored and processed further. The distances and/or angles between the measured points or surfaces may be displayed directly on a display attached to a scanning system or on the mobile phone to which the position information is transmitted.

As a non-limiting example, a scanning system may comprise two or more flexible movable laser sources to project points and further one movable laser source projecting a line. The line may be used to arrange the two or more laser spots along a line and the display of the scanning device may display the distance between the two or more laser spots that may be arranged along the line, such as at equal distance. In the case of two laser spots, a single laser source may be used whereas the distance of the projected points is modified using one or more beam-splitters or prisms, where a beam-splitter or prism can be moved as such that the projected laser spots move apart or closer together. Further, the scanning system may be adapted to project further patterns such as a right angle, a circle, a square, a triangle, or the like, along which a measurement can be done by projecting laser spots and measuring their position.

As a non-limiting example, the scanning system may be adapted to support the work with tools, such as wood or metal processing tools, such as a saw, a driller, or the like. Thus, the scanning system may be adapted to measure the distance in two opposite directions and display the two measured distances or the sum of the distances in a display. Further, the scanning system may be adapted to measure the distance to the edge of a surface as such that when the scanning system is placed on the surface, a laser point is moved automatically away from the scanning system along the surface, until the distance measurement shows a sudden change due to a corner or the edge of a surface. This makes it possible to measure the distance of the end of a wood plank while the scanning device is placed on the plank but remote from its end. Further, the scanning system may measure the distance of the end of a plank in one direction and project a line or circle or point in a designated distance in the opposite direction. The scanning system may be adapted to project the line or circle or point in a distance depending on the distance measured in the opposite direction such as depending on a predetermined sum distance. This allows working with a tool such as a saw or driller at the projected position while placing the scanning system in a safe distance from the tool and simultaneously perform a process using the tool in a predetermined distance to the edge of the plank. Further, the scanning system may be adapted to project points or lines or the like in two opposite directions in a predetermined distance. When the sum of the distances is changed, only one of the projected distances changes.

As a non-limiting example, the scanning system may be adapted to be placed onto a surface, such as a surface on which a task is performed, such as cutting, sawing, drilling, or the like, and to project a line onto the surface in a predetermined distance that can be adjusted such as with buttons on the scanning device.

As non-limiting examples, the scanning system may be used in safety laser scanners, e.g. in production environments, and/or in 3D-scanning devices as used for determining the shape of an object, such as in connection to 3D-printing, body scanning, quality control, in construction applications, e.g. as range meters, in logistics applications, e.g. for determining the size or volume of a parcel, in household applications, e.g. in robotic vacuum cleaners or lawn mowers, or in other kinds of applications which may include a scanning step.

The optional transfer device can, as explained above, be designed to feed light propagating from the object to the detector to the optical sensor, preferably successively. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the optical sensor. The optional transfer device can also be wholly or partly a constituent part of at least one optional illumination source, for example by the illumination source being designed to provide a light beam having defined optical properties, for example having a defined or precisely known beam profile, for example at least one Gaussian beam, in particular at least one laser beam having a known beam profile.

For potential embodiments of the optional illumination source, reference may be made to WO 2012/110924 A1. Still, other embodiments are feasible. Light emerging from the object can originate in the object itself, but can also optionally have a different origin and propagate from this origin to the object and subsequently toward the transversal and/or longitudinal optical sensor.

5 The latter case can be effected for example by at least one illumination source being used. This illumination source can for example be or comprise an ambient illumination source and/or may be or may comprise an artificial illumination source. By way of example, the detector itself can comprise at least one illumination source, for example at least one laser and/or at least one incandescent lamp and/or at least one semiconductor illumination source, for example, at least
10 one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. On account of their generally defined beam profiles and other properties of handleability, the use of one or a plurality of lasers as illumination source or as part thereof, is particularly preferred. The illumination source itself can be a constituent part of the detector or else be formed independently of the detector. The illumination source can be integrated in particular into the detector, for example a housing of the detector. Alternatively or additionally, at least one illumination
15 source can also be integrated into the at least one beacon device or into one or more of the beacon devices and/or into the object or connected or spatially coupled to the object.

The light emerging from the one or more optional beacon devices can accordingly, alternatively
20 or additionally from the option that said light originates in the respective beacon device itself, emerge from the illumination source and/or be excited by the illumination source. By way of example, the electromagnetic light emerging from the beacon device can be emitted by the beacon device itself and/or be reflected by the beacon device and/or be scattered by the beacon device before it is fed to the detector. In this case, emission and/or scattering of the electro-
25 magnetic radiation can be effected without spectral influencing of the electromagnetic radiation or with such influencing. Thus, by way of example, a wavelength shift can also occur during scattering, for example according to Stokes or Raman. Furthermore, emission of light can be excited, for example, by a primary illumination source, for example by the object or a partial region of the object being excited to generate luminescence, in particular phosphorescence
30 and/or fluorescence. Other emission processes are also possible, in principle. If a reflection occurs, then the object can have for example at least one reflective region, in particular at least one reflective surface. Said reflective surface can be a part of the object itself, but can also be for example a reflector which is connected or spatially coupled to the object, for example a reflector plaque connected to the object. If at least one reflector is used, then it can in turn also be
35 regarded as part of the detector which is connected to the object, for example, independently of other constituent parts of the detector.

The beacon devices and/or the at least one optional illumination source generally may emit light in at least one of: the ultraviolet spectral range, preferably in the range of 200 nm to 380 nm; the
40 visible spectral range (380 nm to 780 nm); the infrared spectral range, preferably in the range of 780 nm to 3.0 micrometers. For thermal imaging applications the target may emit light in the far infrared spectral range, preferably in the range of 3.0 micrometers to 20 micrometers. Most preferably, the at least one illumination source is adapted to emit light in the visible spectral

range, preferably in the range of 500 nm to 780 nm, most preferably at 650 nm to 750 nm or at 690 nm to 700 nm.

5 The feeding of the light beam to the optical sensor can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is produced on the optional sensor area of the optical sensor. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects can be detected. Preferably, the optional transfer device is designed in such a way that the light spot, for example in the case of an object arranged within a visual range of the detector, is arranged completely on a sensor region and/or on a sensor area of the optical sensor. By way of
10 example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

15 In a further aspect, the present invention discloses an inertial measurement unit for use in an electronic device. The electronic device may be a mobile electronic device. The electronic device may be a camera. The electronic device may be a mobile phone. The inertial measurement unit is adapted to receive data determined by at least one inertial measurement unit comprising at least one detector according to the present invention, such as according to one or more of the embodiments referring to a detector as disclosed above or as disclosed in further detail below. As used herein, the term "data determined by the at least one detector" refers to at least
20 one information on the at least one longitudinal coordinate z. The inertial measurement unit further is adapted to receive data determined by at least one further sensor selected from the group consisting of: a wheel speed sensor, a turn rate sensor, an inclination sensor, an orientation sensor, a motion sensor, a magneto hydro dynamic sensor, a force sensor, an angular sensor, an angular rate sensor, a magnetic field sensor, a magnetometer, an accelerometer; a gyroscope. As used herein, the term "data determined by the at least one further sensor" refers to at least one information selected from the group consisting of: angle information; speed information; information on turn rate; information on inclination. The inertial measurement unit is adapted to determine by evaluating the data from the detector and the at least one further sensor at least one property of the electronic device selected from the group consisting of: position
30 in space, relative or absolute motion in space, rotation, acceleration, orientation, angle position, inclination, turn rate, speed. The inertial measurement unit may comprise at least one processor. The processor may be adapted to evaluate data recorded by the further sensor. In particular, the processor may be adapted to determine and/or calculate one or more of spatial position, spatial orientation, movement and velocity. The inertial measurement unit may comprise a plurality of further sensors. The inertial measurement unit may be adapted to fuse information determined from at least two of the further sensors. The inertial measurement unit may be adapted to fuse information of at least two further sensors by using at least one Kalman filter. As outlined above, the detector may be adapted to provide an absolute measurement of the longitudinal
40 coordinate z. The processor, e.g. the evaluation device as described above, may be adapted to fuse the information of the at least two further sensors considering the longitudinal coordinate z. The various sensor signals may be used within a Kalman filter or a linear quadratic estimated to take into account that each sensor signal is subject to measurement errors and inaccuracies.

Fusion of these sensor signals within a Kalman filter may yield an improved estimate such as for the measurement of the longitudinal coordinate.

In a further aspect, the present invention discloses a method for determining a position of at least one object by using a detector, such as a detector according to the present invention, such as according to one or more of the embodiments referring to a detector as disclosed above or as disclosed in further detail below. Still, other types of detectors may be used.

The method comprises the following method steps, wherein the method steps may be performed in the given order or may be performed in a different order. Further, one or more additional method steps may be present which are not listed. Further, one, more than one or even all of the method steps may be performed repeatedly.

The method steps are as follows:

- providing at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different separations, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by a light;
- illuminating the at least two light-sensitive areas of the at least two optical sensors of the detector with a light beam propagating from the object to the detector and, thereby, generating at least two sensor signals; and
- evaluating the sensor signals by combining the at least two sensor signals, thereby determining at least one longitudinal coordinate z of the object.

Specifically, evaluating the first and second sensor signal may comprise deriving a quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals, and wherein the determining of the longitudinal coordinate comprises evaluating the quotient signal Q . Further, the determining of the longitudinal coordinate may comprise evaluating the quotient signal Q .

For details, options and definitions, reference may be made to the detector as discussed above. Thus, specifically, as outlined above, the method may comprise using the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below.

In a further aspect of the present invention, use of the detector according to the present invention, such as according to one or more of the embodiments given above or given in further detail below, is proposed, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; an optical data storage application; a security application; a surveillance application; a safety application; a human-machine

interface application; a tracking application; a photography application; a machine vision application; a robotics application; a quality control application; a manufacturing application.

The object generally may be a living or non-living object. The detector or the detector system even may comprise the at least one object, the object thereby forming part of the detector system. Preferably, however, the object may move independently from the detector, in at least one spatial dimension. The object generally may be an arbitrary object. In one embodiment, the object may be a rigid object. Other embodiments are feasible, such as embodiments in which the object is a non-rigid object or an object which may change its shape.

As will be outlined in further detail below, the present invention may specifically be used for tracking positions and/or motions of a person, such as for the purpose of controlling machines, gaming or simulation of sports. In this or other embodiments, specifically, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat; an article of clothing; a hat; a shoe.

Thus, generally, the devices according to the present invention, such as the detector, may be applied in various fields of uses. Specifically, the detector may be applied for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; a security application; a human-machine interface application; a tracking application; a photography application; a mapping application for generating maps of at least one space, such as at least one space selected from the group of a room, a building and a street; a mobile application; a webcam; an audio device; a dolby surround audio system; a computer peripheral device; a gaming application; a camera or video application; a security application; a surveillance application; an automotive application; a transport application; a medical application; a sports' application; a machine vision application; a vehicle application; an airplane application; a ship application; a spacecraft application; a building application; a construction application; a cartography application; a manufacturing application. Additionally or alternatively, applications in local and/or global positioning systems may be named, especially landmark-based positioning and/or navigation, specifically for use in cars or other vehicles (such as trains, motorcycles, bicycles, trucks for cargo transportation), robots or for use by pedestrians. Further, indoor positioning systems may be named as potential applications, such as for household applications and/or for robots used in manufacturing, logistics, surveillance, or maintenance technology.

The devices according to the present invention may be used in mobile phones, tablet computers, laptops, smart panels or other stationary or mobile or wearable computer or communication applications. Thus, the devices according to the present invention may be combined with at least one active light source, such as a light source emitting light in the visible range or infrared spectral range, in order to enhance performance. Thus, as an example, the devices according to the present invention may be used as cameras and/or sensors, such as in combination with mobile software for scanning and/or detecting environment, objects and living beings. The devices according to the present invention may even be combined with 2D cameras, such as con-

ventional cameras, in order to increase imaging effects. The devices according to the present invention may further be used for surveillance and/or for recording purposes or as input devices to control mobile devices, especially in combination with voice and/or gesture recognition. Thus, specifically, the devices according to the present invention acting as human-machine interfaces, also referred to as input devices, may be used in mobile applications, such as for controlling other electronic devices or components via the mobile device, such as the mobile phone. As an example, the mobile application including at least one device according to the present invention may be used for controlling a television set, a game console, a music player or music device or other entertainment devices.

Further, the devices according to the present invention may be used in webcams or other peripheral devices for computing applications. Thus, as an example, the devices according to the present invention may be used in combination with software for imaging, recording, surveillance, scanning or motion detection. As outlined in the context of the human-machine interface and/or the entertainment device, the devices according to the present invention are particularly useful for giving commands by facial expressions and/or body expressions. The devices according to the present invention can be combined with other input generating devices like e.g. mouse, keyboard, touchpad, microphone etc. Further, the devices according to the present invention may be used in applications for gaming, such as by using a webcam. Further, the devices according to the present invention may be used in virtual training applications and/or video conferences. Further, devices according to the present invention may be used to recognize or track hands, arms, or objects used in a virtual or augmented reality application, especially when wearing head mounted displays.

Further, the devices according to the present invention may be used in mobile audio devices, television devices and gaming devices, as partially explained above. Specifically, the devices according to the present invention may be used as controls or control devices for electronic devices, entertainment devices or the like. Further, the devices according to the present invention may be used for eye detection or eye tracking, such as in 2D- and 3D-display techniques, especially with transparent displays for augmented reality applications and/or for recognizing whether a display is being looked at and/or from which perspective a display is being looked at. Further, devices according to the present invention may be used to explore a room, boundaries, obstacles, in connection with a virtual or augmented reality application, especially when wearing a head-mounted display.

Further, the devices according to the present invention may be used in or as digital cameras such as DSC cameras and/or in or as reflex cameras such as SLR cameras. For these applications, reference may be made to the use of the devices according to the present invention in mobile applications such as mobile phones, as disclosed above.

Further, the devices according to the present invention may be used for security or surveillance applications. Thus, as an example, at least one device according to the present invention can be combined with one or more digital and/or analogue electronics that will give a signal if an

object is within or outside a predetermined area (e.g. for surveillance applications in banks or museums). Specifically, the devices according to the present invention may be used for optical encryption. Detection by using at least one device according to the present invention can be combined with other detection devices to complement wavelengths, such as with IR, x-ray, UV-VIS, radar or ultrasound detectors. The devices according to the present invention may further be combined with an active infrared light source to allow detection in low light surroundings. The devices according to the present invention are generally advantageous as compared to active detector systems, specifically since the devices according to the present invention avoid actively sending signals which may be detected by third parties, as is the case e.g. in radar applications, ultrasound applications, LIDAR or similar active detector devices. Thus, generally, the devices according to the present invention may be used for an unrecognized and undetectable tracking of moving objects. Additionally, the devices according to the present invention generally are less prone to manipulations and irritations as compared to conventional devices.

Further, given the ease and accuracy of 3D detection by using the devices according to the present invention, the devices according to the present invention generally may be used for facial, body and person recognition and identification. Therein, the devices according to the present invention may be combined with other detection means for identification or personalization purposes such as passwords, finger prints, iris detection, voice recognition or other means. Thus, generally, the devices according to the present invention may be used in security devices and other personalized applications.

Further, the devices according to the present invention may be used as 3D barcode readers for product identification.

In addition to the security and surveillance applications mentioned above, the devices according to the present invention generally can be used for surveillance and monitoring of spaces and areas. Thus, the devices according to the present invention may be used for surveying and monitoring spaces and areas and, as an example, for triggering or executing alarms in case prohibited areas are violated. Thus, generally, the devices according to the present invention may be used for surveillance purposes in building surveillance or museums, optionally in combination with other types of sensors, such as in combination with motion or heat sensors, in combination with image intensifiers or image enhancement devices and/or photomultipliers. Further, the devices according to the present invention may be used in public spaces or crowded spaces to detect potentially hazardous activities such as commitment of crimes such as theft in a parking lot or unattended objects such as unattended baggage in an airport.

Further, the devices according to the present invention may advantageously be applied in camera applications such as video and camcorder applications. Thus, the devices according to the present invention may be used for motion capture and 3D-movie recording. Therein, the devices according to the present invention generally provide a large number of advantages over conventional optical devices. Thus, the devices according to the present invention generally require a lower complexity with regard to optical components. Thus, as an example, the number of

lenses may be reduced as compared to conventional optical devices, such as by providing the devices according to the present invention having one lens only. Due to the reduced complexity, very compact devices are possible, such as for mobile use. Conventional optical systems having two or more lenses with high quality generally are voluminous, such as due to the general
5 need for voluminous beam-splitters. Further, the devices according to the present invention generally may be used for focus/autofocus devices, such as autofocus cameras. Further, the devices according to the present invention may also be used in optical microscopy, especially in confocal microscopy.

10 Further, the devices according to the present invention generally are applicable in the technical field of automotive technology and transport technology. Thus, as an example, the devices according to the present invention may be used as distance and surveillance sensors, such as for adaptive cruise control, emergency brake assist, lane departure warning, surround view, blind spot detection, traffic sign detection, traffic sign recognition, lane recognition, rear cross traffic
15 alert, light source recognition for adapting the head light intensity and range depending on approaching traffic or vehicles driving ahead, adaptive frontlighting systems, automatic control of high beam head lights, adaptive cut-off lights in front light systems, glare-free high beam front lighting systems, marking animals, obstacles, or the like by headlight illumination, rear cross traffic alert, and other driver assistance systems such as advanced driver assistance systems,
20 or other automotive and traffic applications. Further, devices according to the present invention may be used in driver assistance systems anticipating maneuvers of the driver beforehand for collision avoidance or the like. Further, the devices according to the present invention can also be used for velocity and/or acceleration measurements, such as by analyzing a first and second time-derivative of position information gained by using the detector according to the present
25 invention. This feature generally may be applicable in automotive technology, transportation technology or general traffic technology. Applications in other fields of technology are feasible. A specific application in an indoor positioning system may be the detection of positioning of passengers in transportation, more specifically to electronically control the use of safety systems such as airbags. The use of an airbag may be prevented in case the passenger is located
30 as such, that the use of an airbag will cause a severe injury. Further, in vehicles such as cars, trains, planes or the like, especially in autonomous vehicles, devices according to the present invention may be used to determine whether a driver pays attention to the traffic or is distracted, or asleep, or tired, or incapable of driving such as due to the consumption of alcohol or the like.

35 In these or other applications, generally, the devices according to the present invention may be used as standalone devices or in combination with other sensor devices, such as in combination with radar and/or ultrasonic devices. Specifically, the devices according to the present invention may be used for autonomous driving and safety issues. Further, in these applications, the devices according to the present invention may be used in combination with infrared sensors, radar sensors, which are sonic sensors, two-dimensional cameras or other types of sensors.
40 In these applications, the generally passive nature of the devices according to the present invention is advantageous. Thus, since the devices according to the present invention generally do not require emitting signals, the risk of interference of active sensor signals with other signal

sources may be avoided. The devices according to the present invention specifically may be used in combination with recognition software, such as standard image recognition software. Thus, signals and data as provided by the devices according to the present invention typically are readily processable and, therefore, generally require lower calculation power than established 3D measurement systems. Given the low space demand, the devices according to the present invention such as cameras may be placed at virtually any place in a vehicle, such as on or behind a window screen, on a front hood, on bumpers, on lights, on mirrors or other places and the like. Various detectors according to the present invention such as one or more detectors based on the effect disclosed within the present invention can be combined, such as in order to allow autonomously driving vehicles or in order to increase the performance of active safety concepts. Thus, various devices according to the present invention may be combined with one or more other devices according to the present invention and/or conventional sensors, such as in the windows like rear window, side window or front window, on the bumpers or on the lights.

A combination of at least one device according to the present invention such as at least one detector according to the present invention with one or more rain detection sensors is also possible. This is due to the fact that the devices according to the present invention generally are advantageous over conventional sensor techniques such as radar, specifically during heavy rain. A combination of at least one device according to the present invention with at least one conventional sensing technique such as radar may allow for a software to pick the right combination of signals according to the weather conditions.

Further, the devices according to the present invention generally may be used as break assist and/or parking assist and/or for speed measurements. Speed measurements can be integrated in the vehicle or may be used outside the vehicle, such as in order to measure the speed of other cars in traffic control. Further, the devices according to the present invention may be used for detecting free parking spaces in parking lots.

Further, the devices according to the present invention may be used in the fields of medical systems and sports. Thus, in the field of medical technology, surgery robotics, e.g. for use in endoscopes, may be named, since, as outlined above, the devices according to the present invention may require a low volume only and may be integrated into other devices. Specifically, the devices according to the present invention having one lens, at most, may be used for capturing 3D information in medical devices such as in endoscopes. Further, the devices according to the present invention may be combined with an appropriate monitoring software, in order to enable tracking and analysis of movements. This may allow an instant overlay of the position of a medical device, such as an endoscope or a scalpel, with results from medical imaging, such as obtained from magnetic resonance imaging, x-ray imaging, or ultrasound imaging. These applications are specifically valuable e.g. in medical treatments where precise location information is important such as in brain surgery and long-distance diagnosis and tele-medicine. Further, the devices according to the present invention may be used in 3D-body scanning. Body scanning may be applied in a medical context, such as in dental surgery, plastic surgery, bariatric sur-

gery, or cosmetic plastic surgery, or it may be applied in the context of medical diagnosis such as in the diagnosis of myofascial pain syndrome, cancer, body dysmorphic disorder, or further diseases. Body scanning may further be applied in the field of sports to assess ergonomic use or fit of sports equipment.

5

Body scanning may further be used in the context of clothing, such as to determine a suitable size and fitting of clothes. This technology may be used in the context of tailor-made clothes or in the context of ordering clothes or shoes from the internet or at a self-service shopping device such as a micro kiosk device or customer concierge device. Body scanning in the context of clothing is especially important for scanning fully dressed customers.

10

Further, the devices according to the present invention may be used in the context of people counting systems, such as to count the number of people in an elevator, a train, a bus, a car, or a plane, or to count the number of people passing a hallway, a door, an aisle, a retail store, a stadium, an entertainment venue, a museum, a library, a public location, a cinema, a theater, or the like. Further, the 3D-function in the people counting system may be used to obtain or estimate further information about the people that are counted such as height, weight, age, physical fitness, or the like. This information may be used for business intelligence metrics, and/or for further optimizing the locality where people may be counted to make it more attractive or safe.

15

In a retail environment, the devices according to the present invention in the context of people counting may be used to recognize returning customers or cross shoppers, to assess shopping behavior, to assess the percentage of visitors that make purchases, to optimize staff shifts, or to monitor the costs of a shopping mall per visitor. Further, people counting systems may be used for anthropometric surveys. Further, the devices according to the present invention may be used in public transportation systems for automatically charging passengers depending on the length of transport. Further, the devices according to the present invention may be used in playgrounds for children, to recognize injured children or children engaged in dangerous activities, to allow additional interaction with playground toys, to ensure safe use of playground toys or the like.

20

25

30

Further the devices according to the present invention may be used in construction tools, such as a range meter that determines the distance to an object or to a wall, to assess whether a surface is planar, to align objects or place objects in an ordered manner, or in inspection cameras for use in construction environments or the like.

35

Further, the devices according to the present invention may be applied in the field of sports and exercising, such as for training, remote instructions or competition purposes. Specifically, the devices according to the present invention may be applied in the fields of dancing, aerobic, football, soccer, basketball, baseball, cricket, hockey, track and field, swimming, polo, handball, volleyball, rugby, sumo, judo, fencing, boxing, golf, car racing, laser tag, battlefield simulation etc. The devices according to the present invention can be used to detect the position of a ball, a bat, a sword, motions, etc., both in sports and in games, such as to monitor the game, support

40

the referee or for judgment, specifically automatic judgment, of specific situations in sports, such as for judging whether a point or a goal actually was made.

5 Further, the devices according to the present invention may be used in the field of auto racing or car driver training or car safety training or the like to determine the position of a car or the track of a car, or the deviation from a previous track or an ideal track or the like.

10 The devices according to the present invention may further be used to support a practice of musical instruments, in particular remote lessons, for example lessons of string instruments, such as fiddles, violins, violas, celli, basses, harps, guitars, banjos, or ukuleles, keyboard instruments, such as pianos, organs, keyboards, harpsichords, harmoniums, or accordions, and/or percussion instruments, such as drums, timpani, marimbas, xylophones, vibraphones, bongos, congas, timbales, djembes or tablas.

15 The devices according to the present invention further may be used in rehabilitation and physiotherapy, in order to encourage training and/or in order to survey and correct movements. Therein, the devices according to the present invention may also be applied for distance diagnostics.

20 Further, the devices according to the present invention may be applied in the field of machine vision. Thus, one or more of the devices according to the present invention may be used e.g. as a passive controlling unit for autonomous driving and/or working of robots. In combination with moving robots, the devices according to the present invention may allow for autonomous movement and/or autonomous detection of failures in parts. The devices according to the present invention may also be used for manufacturing and safety surveillance, such as in order to
25 avoid accidents including but not limited to collisions between robots, production parts and living beings. In robotics, the safe and direct interaction of humans and robots is often an issue, as robots may severely injure humans when they are not recognized. Devices according to the present invention may help robots to position objects and humans better and faster and allow a safe interaction. Given the passive nature of the devices according to the present invention, the
30 devices according to the present invention may be advantageous over active devices and/or may be used complementary to existing solutions like radar, ultrasound, 2D cameras, IR detection etc. One particular advantage of the devices according to the present invention is the low likelihood of signal interference. Therefore multiple sensors can work at the same time in the same environment, without the risk of signal interference. Thus, the devices according to the
35 present invention generally may be useful in highly automated production environments like e.g. but not limited to automotive, mining, steel, etc. The devices according to the present invention can also be used for quality control in production, e.g. in combination with other sensors like 2-D imaging, radar, ultrasound, IR etc., such as for quality control or other purposes. Further, the devices according to the present invention may be used for assessment of surface quality, such
40 as for surveying the surface evenness of a product or the adherence to specified dimensions, from the range of micrometers to the range of meters. Other quality control applications are feasible. In a manufacturing environment, the devices according to the present invention are especially useful for processing natural products such as food or wood, with a complex 3-

dimensional structure to avoid large amounts of waste material. Further, devices according to the present invention may be used to monitor the filling level of tanks, silos etc. Further, devices according to the present invention may be used to inspect complex products for missing parts, incomplete parts, loose parts, low quality parts, or the like, such as in automatic optical inspection, such as of printed circuit boards, inspection of assemblies or sub-assemblies, verification of engineered components, engine part inspections, wood quality inspection, label inspections, inspection of medical devices, inspection of product orientations, packaging inspections, food pack inspections, or the like.

Further, the devices according to the present invention may be used in vehicles, trains, airplanes, ships, spacecraft and other traffic applications. Thus, besides the applications mentioned above in the context of traffic applications, passive tracking systems for aircraft, vehicles and the like may be named. The use of at least one device according to the present invention, such as at least one detector according to the present invention, for monitoring the speed and/or the direction of moving objects is feasible. Specifically, the tracking of fast moving objects on land, sea and in the air including space may be named. The at least one device according to the present invention, such as the at least one detector according to the present invention, specifically may be mounted on a still-standing and/or on a moving device. An output signal of the at least one device according to the present invention can be combined e.g. with a guiding mechanism for autonomous or guided movement of another object. Thus, applications for avoiding collisions or for enabling collisions between the tracked and the steered object are feasible. The devices according to the present invention generally are useful and advantageous due to the low calculation power required, the instant response and due to the passive nature of the detection system which generally is more difficult to detect and to disturb as compared to active systems, like e.g. radar. The devices according to the present invention are particularly useful but not limited to e.g. speed control and air traffic control devices. Further, the devices according to the present invention may be used in automated tolling systems for road charges.

The devices according to the present invention generally may be used in passive applications. Passive applications include guidance for ships in harbors or in dangerous areas, and for aircraft when landing or starting. Therein, fixed, known active targets may be used for precise guidance. The same can be used for vehicles driving on dangerous but well defined routes, such as mining vehicles. Further, the devices according to the present invention may be used to detect rapidly approaching objects, such as cars, trains, flying objects, animals, or the like. Further, the devices according to the present invention can be used for detecting velocities or accelerations of objects, or to predict the movement of an object by tracking one or more of its position, speed, and/or acceleration depending on time.

Further, as outlined above, the devices according to the present invention may be used in the field of gaming. Thus, the devices according to the present invention can be passive for use with multiple objects of the same or of different size, color, shape, etc., such as for movement detection in combination with software that incorporates the movement into its content. In particular, applications are feasible in implementing movements into graphical output. Further, ap-

plications of the devices according to the present invention for giving commands are feasible, such as by using one or more of the devices according to the present invention for gesture or facial recognition. The devices according to the present invention may be combined with an active system in order to work under e.g. low light conditions or in other situations in which enhancement of the surrounding conditions is required. Additionally or alternatively, a combination of one or more devices according to the present invention with one or more IR or VIS light sources is possible. A combination of a detector according to the present invention with special devices is also possible, which can be distinguished easily by the system and its software, e.g. and not limited to, a special color, shape, relative position to other devices, speed of movement, light, frequency used to modulate light sources on the device, surface properties, material used, reflection properties, transparency degree, absorption characteristics, etc. The device can, amongst other possibilities, resemble a stick, a racket, a club, a gun, a knife, a wheel, a ring, a steering wheel, a bottle, a ball, a glass, a vase, a spoon, a fork, a cube, a dice, a figure, a puppet, a teddy, a beaker, a pedal, a switch, a glove, jewelry, a musical instrument or an auxiliary device for playing a musical instrument, such as a plectrum, a drumstick or the like. Other options are feasible.

Further, the devices according to the present invention may be used to detect and or track objects that emit light by themselves, such as due to high temperature or further light emission processes. The light emitting part may be an exhaust stream or the like. Further, the devices according to the present invention may be used to track reflecting objects and analyze the rotation or orientation of these objects.

Further, the devices according to the present invention generally may be used in the field of building, construction and cartography. Thus, generally, one or more devices according to the present invention may be used in order to measure and/or monitor environmental areas, e.g. countryside or buildings. Therein, one or more devices according to the present invention may be combined with other methods and devices or can be used solely in order to monitor progress and accuracy of building projects, changing objects, houses, etc. The devices according to the present invention can be used for generating three-dimensional models of scanned environments, in order to construct maps of rooms, streets, houses, communities or landscapes, both from ground or from air. Potential fields of application may be construction, cartography, real estate management, land surveying or the like. As an example, the devices according to the present invention may be used in drones or multicopters or the like to monitor buildings, production sites, chimneys, agricultural production environments such as fields, production plants, or landscapes, to support rescue operations, to support work in dangerous environments, to support fire brigades in a burning location indoors or outdoors, or to find or monitor one or more persons or animals, or the like, or for entertainment purposes, such as a drone following and recording one or more persons doing sports such as skiing or cycling or the like, which could be realized by following a helmet, a mark, a beacon device, or the like. Devices according to the present invention could be used to recognize obstacles, follow a predefined route, follow an edge, a pipe, a building, or the like, or to record a global or local map of the environment. Further, devices according to the present invention could be used for indoor or outdoor localization

and positioning of drones, for stabilizing the height of a drone indoors where barometric pressure sensors are not accurate enough, or for the interaction of multiple drones such as concerted movements of several drones or recharging or refueling in the air or the like.

5 Further, the devices according to the present invention may be used within an interconnecting network of home appliances such as CHAIN (Cedec Home Appliances Interoperating Network) to interconnect, automate, and control basic appliance-related services in a home, e.g. energy or load management, remote diagnostics, pet-related appliances, child-related appliances, child surveillance, appliance related surveillance, support or service to elderly or ill persons, home
10 security and/or surveillance, remote control of appliance operation, and automatic maintenance support. Further, the devices according to the present invention may be used in heating or cooling systems such as an air-conditioning system, to locate which part of the room should be brought to a certain temperature or humidity, especially depending on the location of one or more persons. Further, the devices according to the present invention may be used in domestic
15 robots, such as service or autonomous robots which may be used for household chores. The devices according to the present invention may be used for a number of different purposes, such as to avoid collisions or to map the environment, but also to identify a user, to personalize the robot's performance for a given user, for security purposes, or for gesture or facial recognition. As an example, the devices according to the present invention may be used in robotic vacuum cleaners, floor-washing robots, dry-sweeping robots, ironing robots for ironing clothes, animal litter robots, such as cat litter robots, security robots that detect intruders, robotic lawn mowers, automated pool cleaners, rain gutter cleaning robots, window washing robots, toy robots, telepresence robots, social robots providing company to less mobile people, or robots translating and speech to sign language or sign language to speech. In the context of less mobile people, such as elderly persons, household robots with the devices according to the present invention may be used for picking up objects, transporting objects, and interacting with the objects and the user in a safe way. Further, the devices according to the present invention may be used in robots operating with hazardous materials or objects or in dangerous environments. As a non-limiting example, the devices according to the present invention may be used in robots
30 or unmanned remote-controlled vehicles to operate with hazardous materials such as chemicals or radioactive materials especially after disasters, or with other hazardous or potentially hazardous objects such as mines, unexploded arms, or the like, or to operate in or to investigate insecure environments such as near burning objects or post disaster areas or for manned or unmanned rescue operations in the air, in the sea, underground, or the like.

35 Further, devices according to the present invention may be used for navigation purposes, where Global Positioning Systems (GPS) are not sufficiently reliable. GPS signals commonly use radio waves that can be blocked or difficult to receive indoors or outdoors in valleys or in forests below the treeline. Further, especially in unmanned autonomous vehicles, the weight of the system may be critical. Especially unmanned autonomous vehicles need high-speed position data for reliable feedback and stability of their control systems. Using devices according to the present invention may allow short time response and positioning without adding weight due to a heavy device.
40

- Further, the devices according to the present invention may be used in household, mobile or entertainment devices, such as a refrigerator, a microwave, a washing machine, a window blind or shutter, a household alarm, an air condition device, a heating device, a television, an audio device, a smart watch, a mobile phone, a phone, a dishwasher, a stove or the like, to detect the presence of a person, to monitor the contents or function of the device, or to interact with the person and/or share information about the person with further household, mobile or entertainment devices.
- Further, the devices according to the present invention may be used to support elderly or disabled persons or persons with limited or no vision, such as in household chores or at work such as in devices for holding, carrying, or picking objects, or in a safety system with optical or acoustical signals signaling obstacles in the environment.
- The devices according to the present invention may further be used in agriculture, for example to detect and sort out vermin, weeds, and/or infected crop plants, fully or in parts, wherein crop plants may be infected by fungus or insects. Further, for harvesting crops, the devices according to the present invention may be used to detect animals, such as deer, which may otherwise be harmed by harvesting devices. Further, the devices according to the present invention may be used to monitor the growth of plants in a field or greenhouse, in particular to adjust the amount of water or fertilizer or crop protection products for a given region in the field or greenhouse or even for a given plant. Further, in agricultural biotechnology, the devices according to the present invention may be used to monitor the size and shape of plants.
- Further, devices according to the present invention may be used to automatically remove weeds such as with mechanical means, such as to avoid the use of herbicides. Further, devices according to the present invention may be used in the field of agriculture, in particular to detect and/or locate specific insects such as to decide whether or not to apply a crop protection or fertilization substance, such as to reduce the amount of applied substance or to protect specific groups of animals such as bees.
- Further, the devices according to the present invention may be combined with sensors to detect chemicals or pollutants, electronic nose chips, microbe sensor chips to detect bacteria or viruses or the like, Geiger counters, tactile sensors, heat sensors, or the like. This may for example be used in constructing smart robots which are configured for handling dangerous or difficult tasks, such as in treating highly infectious patients, handling or removing highly dangerous substances, cleaning highly polluted areas, such as highly radioactive areas or chemical spills, or for pest control in agriculture.
- One or more devices according to the present invention can further be used for scanning of objects, such as in combination with CAD or similar software, such as for additive manufacturing and/or 3D printing. Therein, use may be made of the high dimensional accuracy of the devices according to the present invention, e.g. in x-, y- or z- direction or in any arbitrary combination of these directions, such as simultaneously. Further, the devices according to the present inven-

tion may be used in inspections and maintenance, such as pipeline inspection gauges. Further, in a production environment, the devices according to the present invention may be used to work with objects of a badly defined shape such as naturally grown objects, such as sorting vegetables or other natural products by shape or size or cutting products such as meat or objects that are manufactured with a precision that is lower than the precision needed for a processing step.

Further, the devices according to the present invention may be used in local navigation systems to allow autonomously or partially autonomously moving vehicles or multicopters or the like through an indoor or outdoor space. A non-limiting example may comprise vehicles moving through an automated storage for picking up objects and placing them at a different location. Indoor navigation may further be used in shopping malls, retail stores, museums, airports, or train stations, to track the location of mobile goods, mobile devices, baggage, customers or employees, or to supply users with a location-specific information, such as the current position on a map, or information on goods sold, or the like.

Further, the devices according to the present invention may be used to ensure safe driving of motorcycles such as driving assistance for motorcycles by monitoring speed, inclination, upcoming obstacles, unevenness of the road, or curves or the like. Further, the devices according to the present invention may be used in trains or trams to avoid collisions.

Further, the devices according to the present invention may be used in handheld devices, such as for scanning packaging or parcels to optimize a logistics process. Further, the devices according to the present invention may be used in further handheld devices such as personal shopping devices, RFID-readers, handheld devices for use in hospitals or health environments such as for medical use or to obtain, exchange or record patient or patient health related information, smart badges for retail or health environments, or the like.

As outlined above, the devices according to the present invention may further be used in manufacturing, quality control or identification applications, such as in product identification or size identification (such as for finding an optimal place or package, for reducing waste etc.). Further, the devices according to the present invention may be used in logistics applications. Thus, the devices according to the present invention may be used for optimized loading or packing containers or vehicles. Further, the devices according to the present invention may be used for monitoring or controlling of surface damages in the field of manufacturing, for monitoring or controlling rental objects such as rental vehicles, and/or for insurance applications, such as for assessment of damages. Further, the devices according to the present invention may be used for identifying a size of material, object or tools, such as for optimal material handling, especially in combination with robots. Further, the devices according to the present invention may be used for process control in production, e.g. for observing filling level of tanks. Further, the devices according to the present invention may be used for maintenance of production assets like, but not limited to, tanks, pipes, reactors, tools etc. Further, the devices according to the present invention may be used for analyzing 3D-quality marks. Further, the devices according to the

present invention may be used in manufacturing tailor-made goods such as tooth inlays, dental braces, prosthesis, clothes or the like. The devices according to the present invention may also be combined with one or more 3D-printers for rapid prototyping, 3D-copying or the like. Further, the devices according to the present invention may be used for detecting the shape of one or more articles, such as for anti-product piracy and for anti-counterfeiting purposes.

Thus, specifically, the present application may be applied in the field of photography. Thus, the detector may be part of a photographic device, specifically of a digital camera. Specifically, the detector may be used for 3D photography, specifically for digital 3D photography. Thus, the detector may form a digital 3D camera or may be part of a digital 3D camera. As used herein, the term photography generally refers to the technology of acquiring image information of at least one object. As further used herein, a camera generally is a device adapted for performing photography. As further used herein, the term digital photography generally refers to the technology of acquiring image information of at least one object by using a plurality of light-sensitive elements adapted to generate electrical signals indicating an intensity and/or color of illumination, preferably digital electrical signals. As further used herein, the term 3D photography generally refers to the technology of acquiring image information of at least one object in three spatial dimensions. Accordingly, a 3D camera is a device adapted for performing 3D photography. The camera generally may be adapted for acquiring a single image, such as a single 3D image, or may be adapted for acquiring a plurality of images, such as a sequence of images. Thus, the camera may also be a video camera adapted for video applications, such as for acquiring digital video sequences.

Thus, generally, the present invention further refers to a camera, specifically a digital camera, more specifically a 3D camera or digital 3D camera, for imaging at least one object. As outlined above, the term imaging, as used herein, generally refers to acquiring image information of at least one object. The camera comprises at least one detector according to the present invention. The camera, as outlined above, may be adapted for acquiring a single image or for acquiring a plurality of images, such as image sequence, preferably for acquiring digital video sequences. Thus, as an example, the camera may be or may comprise a video camera. In the latter case, the camera preferably comprises a data memory for storing the image sequence.

As used within the present invention, the expression "position" generally refers to at least one item of information regarding one or more of an absolute position and an orientation of one or more points of the object. Thus, specifically, the position may be determined in a coordinate system of the detector, such as in a Cartesian coordinate system. Additionally or alternatively, however, other types of coordinate systems may be used, such as polar coordinate systems and/or spherical coordinate systems.

As outlined above and as will be outlined in further detail below, the present invention preferably may be applied in the field of human-machine interfaces, in the field of sports and/or in the field of computer games. Thus, preferably, the object may be selected from the group consisting of: an article of sports equipment, preferably an article selected from the group consisting of a racket, a club, a bat, an article of clothing, a hat, a shoe. Other embodiments are feasible.

As used herein, the object generally may be an arbitrary object, chosen from a living object and a non-living object. Thus, as an example, the at least one object may comprise one or more articles and/or one or more parts of an article. Additionally or alternatively, the object may be or
5 may comprise one or more living beings and/or one or more parts thereof, such as one or more body parts of a human being, e.g. a user, and/or an animal.

With regard to the coordinate system for determining the position of the object, which may be a coordinate system of the detector, the detector may constitute a coordinate system in which an
10 optical axis of the detector forms the z-axis and in which, additionally, an x-axis and a y-axis may be provided which are perpendicular to the z-axis and which are perpendicular to each other. As an example, the detector and/or a part of the detector may rest at a specific point in this coordinate system, such as at the origin of this coordinate system. In this coordinate system, a direction parallel or antiparallel to the z-axis may be regarded as a longitudinal direction,
15 and a coordinate along the z-axis may be considered a longitudinal coordinate. An arbitrary direction perpendicular to the longitudinal direction may be considered a transversal direction, and an x- and/or y-coordinate may be considered a transversal coordinate.

Alternatively, other types of coordinate systems may be used. Thus, as an example, a polar
20 coordinate system may be used in which the optical axis forms a z-axis and in which a distance from the z-axis and a polar angle may be used as additional coordinates. Again, a direction parallel or antiparallel to the z-axis may be considered a longitudinal direction, and a coordinate along the z-axis may be considered a longitudinal coordinate. Any direction perpendicular to the z-axis may be considered a transversal direction, and the polar coordinate and/or the polar angle
25 may be considered a transversal coordinate.

The detector may be a device configured for providing at least one item of information on the position of the at least one object and/or a part thereof. Thus, the position may refer to an item of information fully describing the position of the object or a part thereof, preferably in the coordinate system of the detector, or may refer to a partial information, which only partially describes
30 the position. The detector generally may be a device adapted for detecting light beams, such as the light beams propagating from the beacon devices towards the detector.

The evaluation device and the detector may fully or partially be integrated into a single device.
35 Thus, generally, the evaluation device also may form part of the detector. Alternatively, the evaluation device and the detector may fully or partially be embodied as separate devices. The detector may comprise further components.

The detector may be a stationary device or a mobile device. Further, the detector may be a
40 stand-alone device or may form part of another device, such as a computer, a vehicle or any other device. Further, the detector may be a hand-held device. Other embodiments of the detector are feasible.

The detector specifically may be used to record a light-field behind a lens or lens system of the detector, comparable to a plenoptic or light-field camera. Thus, specifically, the detector may be embodied as a light-field camera adapted for acquiring images in multiple focal planes, such as simultaneously. The term light-field, as used herein, generally refers to the spatial light propagation of light inside the detector such as inside the camera. The detector according to the present invention, specifically having a stack of optical sensors, may have the capability of directly recording a light-field within the detector or camera, such as behind a lens. The plurality of sensors may record images at different distances from the lens. Using, e.g., convolution-based algorithms such as "depth from focus" or "depth from defocus", the propagation direction, focus points, and spread of the light behind the lens can be modeled. From the modeled propagation of light behind the lens, images at various distances to the lens can be extracted, the depth of field can be optimized, pictures that are in focus at various distances can be extracted, or distances of objects can be calculated. Further information may be extracted.

The use of several optical sensors further allows for correcting lens errors in an image processing step after recording the images. Optical instruments often become expensive and challenging in construction, when lens errors need to be corrected. These are especially problematic in microscopes and telescopes. In microscopes, a typical lens error is that rays of varying distance to the optical axis are distorted differently (spherical aberration). In telescopes, varying the focus may occur from differing temperatures in the atmosphere. Static errors such as spherical aberration or further errors from production may be corrected by determining the errors in a calibration step and then using a fixed image processing such as fixed set of pixels and sensor, or more involved processing techniques using light propagation information. In cases in which lens errors are strongly time-dependent, i.e. dependent on weather conditions in telescopes, the lens errors may be corrected by using the light propagation behind the lens, calculating extended depth of field images, using depth from focus techniques, and others.

The detector according to the present invention may further allow for color detection. For color detection, a plurality of optical sensors having different spectral properties may be used, and sensor signals of these optical sensors may be compared.

The evaluation device may be or may comprise one or more integrated circuits, such as one or more application-specific integrated circuits (ASICs), and/or one or more data processing devices, such as one or more computers, preferably one or more microcomputers and/or microcontrollers. Additional components may be comprised, such as one or more preprocessing devices and/or data acquisition devices, such as one or more devices for receiving and/or preprocessing of the sensor signals, such as one or more AD-converters and/or one or more filters. Further, the evaluation device may comprise one or more measurement devices, such as one or more measurement devices for measuring electrical currents and/or electrical voltages. Further, the evaluation device may comprise one or more data storage devices. Further, the evaluation device may comprise one or more interfaces, such as one or more wireless interfaces and/or one or more wire-bound interfaces.

The at least one evaluation device may be adapted to perform at least one computer program, such as at least one computer program adapted for performing or supporting one or more or even all of the method steps of the method according to the present invention. As an example, one or more algorithms may be implemented which, by using the sensor signals as input variables, may determine the position of the object.

The evaluation device can be connected to or may comprise at least one further data processing device that may be used for one or more of displaying, visualizing, analyzing, distributing, communicating or further processing of information, such as information obtained by the optical sensor and/or by the evaluation device. The data processing device, as an example, may be connected or incorporate at least one of a display, a projector, a monitor, an LCD, a TFT, a loudspeaker, a multichannel sound system, an LED pattern, or a further visualization device. It may further be connected or incorporate at least one of a communication device or communication interface, a connector or a port, capable of sending encrypted or unencrypted information using one or more of email, text messages, telephone, Bluetooth, Wi-Fi, infrared or internet interfaces, ports or connections. It may further be connected or incorporate at least one of a processor, a graphics processor, a CPU, an Open Multimedia Applications Platform (OMAP™), an integrated circuit, a system on a chip such as products from the Apple A series or the Samsung S3C2 series, a microcontroller or microprocessor, one or more memory blocks such as ROM, RAM, EEPROM, or flash memory, timing sources such as oscillators or phase-locked loops, counter-timers, real-time timers, or power-on reset generators, voltage regulators, power management circuits, or DMA controllers. Individual units may further be connected by buses such as AMBA buses or be integrated in an Internet of Things or Industry 4.0 type network.

The evaluation device and/or the data processing device may be connected by or have further external interfaces or ports such as one or more of serial or parallel interfaces or ports, USB, Centronics Port, FireWire, HDMI, Ethernet, Bluetooth, RFID, Wi-Fi, USART, or SPI, or analogue interfaces or ports such as one or more of ADCs or DACs, or standardized interfaces or ports to further devices such as a 2D-camera device using an RGB-interface such as CameraLink. The evaluation device and/or the data processing device may further be connected by one or more of interprocessor interfaces or ports, FPGA-FPGA-interfaces, or serial or parallel interfaces ports. The evaluation device and the data processing device may further be connected to one or more of an optical disc drive, a CD-RW drive, a DVD+RW drive, a flash drive, a memory card, a disk drive, a hard disk drive, a solid state disk or a solid state hard disk.

The evaluation device and/or the data processing device may be connected by or have one or more further external connectors such as one or more of phone connectors, RCA connectors, VGA connectors, hermaphrodite connectors, USB connectors, HDMI connectors, 8P8C connectors, BCN connectors, IEC 60320 C14 connectors, optical fiber connectors, D-subminiature connectors, RF connectors, coaxial connectors, SCART connectors, XLR connectors, and/or may incorporate at least one suitable socket for one or more of these connectors.

Possible embodiments of a single device incorporating one or more of the detectors according to the present invention, the evaluation device or the data processing device, such as incorporating one or more of the optical sensor, optical systems, evaluation device, communication device, data processing device, interfaces, system on a chip, display devices, or further electronic devices, are: mobile phones, personal computers, tablet PCs, televisions, game consoles or further entertainment devices. In a further embodiment, the 3D-camera functionality which will be outlined in further detail below may be integrated in devices that are available with conventional 2D-digital cameras, without a noticeable difference in the housing or appearance of the device, where the noticeable difference for the user may only be the functionality of obtaining and or processing 3D information.

Specifically, an embodiment incorporating the detector and/or a part thereof such as the evaluation device and/or the data processing device may be: a mobile phone incorporating a display device, a data processing device, the optical sensor, optionally the sensor optics, and the evaluation device, for the functionality of a 3D camera. The detector according to the present invention specifically may be suitable for integration in entertainment devices and/or communication devices such as a mobile phone.

A further embodiment of the present invention may be an incorporation of the detector or a part thereof such as the evaluation device and/or the data processing device in a device for use in automotive, for use in autonomous driving or for use in car safety systems such as Daimler's Intelligent Drive system, wherein, as an example, a device incorporating one or more of the optical sensors, optionally one or more optical systems, the evaluation device, optionally a communication device, optionally a data processing device, optionally one or more interfaces, optionally a system on a chip, optionally one or more display devices, or optionally further electronic devices may be part of a vehicle, a car, a truck, a train, a bicycle, an airplane, a ship, a motorcycle. In automotive applications, the integration of the device into the automotive design may necessitate the integration of the optical sensor, optionally optics, or device at minimal visibility from the exterior or interior. The detector or a part thereof such as the evaluation device and/or the data processing device may be especially suitable for such integration into automotive design.

As used herein, the term light generally refers to electromagnetic radiation in one or more of the visible spectral range, the ultraviolet spectral range and the infrared spectral range. Therein, the term visible spectral range generally refers to a spectral range of 380 nm to 780 nm. The term infrared spectral range generally refers to electromagnetic radiation in the range of 780 nm to 1 mm, preferably in the range of 780 nm to 3.0 micrometers. The term ultraviolet spectral range generally refers to electromagnetic radiation in the range of 1 nm to 380 nm, preferably in the range of 100 nm to 380 nm. Preferably, light as used within the present invention is visible light, i.e. light in the visible spectral range.

The term light beam generally may refer to an amount of light emitted and/or reflected into a specific direction. Thus, the light beam may be a bundle of the light rays having a predeter-

mined extension in a direction perpendicular to a direction of propagation of the light beam. Preferably, the light beams may be or may comprise one or more Gaussian light beams such as a linear combination of Gaussian light beams, which may be characterized by one or more Gaussian beam parameters, such as one or more of a beam waist, a Rayleigh-length or any other beam parameter or combination of beam parameters suited to characterize a development of a beam diameter and/or a beam propagation in space.

The detector according to the present invention may further be combined with one or more other types of sensors or detectors. Thus, the detector may further comprise at least one additional detector. The at least one additional detector may be adapted for detecting at least one parameter, such as at least one of: a parameter of a surrounding environment, such as a temperature and/or a brightness of a surrounding environment; a parameter regarding a position and/or orientation of the detector; a parameter specifying a state of the object to be detected, such as a position of the object, e.g. an absolute position of the object and/or an orientation of the object in space. Thus, generally, the principles of the present invention may be combined with other measurement principles in order to gain additional information and/or in order to verify measurement results or reduce measurement errors or noise.

As outlined above, the human-machine interface may comprise a plurality of beacon devices which are adapted to be at least one of directly or indirectly attached to the user and held by the user. Thus, the beacon devices each may independently be attached to the user by any suitable means, such as by an appropriate fixing device. Additionally or alternatively, the user may hold and/or carry the at least one beacon device or one or more of the beacon devices in his or her hands and/or by wearing the at least one beacon device and/or a garment containing the beacon device on a body part.

The beacon device generally may be an arbitrary device which may be detected by the at least one detector and/or which facilitates detection by the at least one detector. Thus, as outlined above or as will be outlined in further detail below, the beacon device may be an active beacon device adapted for generating the at least one light beam to be detected by the detector, such as by having one or more illumination sources for generating the at least one light beam. Additionally or alternatively, the beacon device may fully or partially be designed as a passive beacon device, such as by providing one or more reflective elements adapted to reflect a light beam generated by a separate illumination source. The at least one beacon device may permanently or temporarily be attached to the user in a direct or indirect way and/or may be carried or held by the user. The attachment may take place by using one or more attachment means and/or by the user himself or herself, such as by the user holding the at least one beacon device by hand and/or by the user wearing the beacon device.

Additionally or alternatively, the beacon devices may be at least one of attached to an object and integrated into an object held by the user, which, in the sense of the present invention, shall be included into the meaning of the option of the user holding the beacon devices. Thus, as will

be outlined in further detail below, the beacon devices may be attached to or integrated into a control element which may be part of the human-machine interface and which may be held or carried by the user, and of which the orientation may be recognized by the detector device.

Thus, generally, the present invention also refers to a detector system comprising at least one detector device according to the present invention and which, further, may comprise at least one object, wherein the beacon devices are one of attached to the object, held by the object and integrated into the object. As an example, the object preferably may form a control element, the orientation of which may be recognized by a user. Thus, the detector system may be part of the human-machine interface as outlined above or as outlined in further detail below. As an example, the user may handle the control element in a specific way in order to transmit one or more items of information to a machine, such as in order to transmit one or more commands to the machine.

Alternatively, the detector system may be used in other ways. Thus, as an example, the object of the detector system may be different from a user or a body part of the user and, as an example, may be an object which moves independently from the user. As an example, the detector system may be used for controlling apparatuses and/or industrial processes, such as manufacturing processes and/or robotics processes. Thus, as an example, the object may be a machine and/or a machine part, such as a robot arm, the orientation of which may be detected by using the detector system.

The human-machine interface may be adapted in such a way that the detector device generates at least one item of information on the position of the user or of at least one body part of the user. Specifically in case a manner of attachment of the at least one beacon device to the user is known, by evaluating the position of the at least one beacon device, at least one item of information on a position and/or an orientation of the user or of a body part of the user may be gained.

The beacon device preferably is one of a beacon device attachable to a body or a body part of the user and a beacon device which may be held by the user. As outlined above, the beacon device may fully or partially be designed as an active beacon device. Thus, the beacon device may comprise at least one illumination source adapted to generate at least one light beam to be transmitted to the detector, preferably at least one light beam having known beam properties. Additionally or alternatively, the beacon device may comprise at least one reflector adapted to reflect light generated by an illumination source, thereby generating a reflected light beam to be transmitted to the detector.

The object, which may form part of the detector system, may generally have an arbitrary shape. Preferably, the object being part of the detector system, as outlined above, may be a control element which may be handled by a user, such as manually. As an example, the control element may be or may comprise at least one element selected from the group consisting of: a glove, a jacket, a hat, shoes, trousers and a suit, a stick that may be held by hand, a bat, a club,

a racket, a cane, a toy, such as a toy gun. Thus, as an example, the detector system may be part of the human-machine interface and/or of the entertainment device.

As used herein, an entertainment device is a device which may serve the purpose of leisure and/or entertainment of one or more users, in the following also referred to as one or more players. As an example, the entertainment device may serve the purpose of gaming, preferably computer gaming. Thus, the entertainment device may be implemented into a computer, a computer network or a computer system or may comprise a computer, a computer network or a computer system which runs one or more gaming software programs.

The entertainment device comprises at least one human-machine interface according to the present invention, such as according to one or more of the embodiments disclosed above and/or according to one or more of the embodiments disclosed below. The entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface. The at least one item of information may be transmitted to and/or may be used by a controller and/or a computer of the entertainment device. The at least one item of information preferably may comprise at least one command adapted for influencing the course of a game. Thus, as an example, the at least one item of information may include at least one item of information on at least one orientation of the player and/or of one or more body parts of the player, thereby allowing for the player to simulate a specific position and/or orientation and/or action required for gaming. As an example, one or more of the following movements may be simulated and communicated to a controller and/or a computer of the entertainment device: dancing; running; jumping; swinging of a racket; swinging of a bat; swinging of a club; pointing of an object towards another object, such as pointing of a toy gun towards a target.

The entertainment device as a part or as a whole, preferably a controller and/or a computer of the entertainment device, is designed to vary the entertainment function in accordance with the information. Thus, as outlined above, a course of a game might be influenced in accordance with the at least one item of information. Thus, the entertainment device might include one or more controllers which might be separate from the evaluation device of the at least one detector and/or which might be fully or partially identical to the at least one evaluation device or which might even include the at least one evaluation device. Preferably, the at least one controller might include one or more data processing devices, such as one or more computers and/or microcontrollers.

As further used herein, a tracking system is a device which is adapted to gather information on a series of past positions of the at least one object and/or at least one part of the object. Additionally, the tracking system may be adapted to provide information on at least one predicted future position and/or orientation of the at least one object or the at least one part of the object. The tracking system may have at least one track controller, which may fully or partially be embodied as an electronic device, preferably as at least one data processing device, more preferably as at least one computer or microcontroller. Again, the at least one track controller may fully or partially comprise the at least one evaluation device and/or may be part of the at least

one evaluation device and/or may fully or partially be identical to the at least one evaluation device.

5 The tracking system comprises at least one detector according to the present invention, such as at least one detector as disclosed in one or more of the embodiments listed above and/or as disclosed in one or more of the embodiments below. The tracking system further comprises at least one track controller. The track controller is adapted to track a series of positions of the object at specific points in time, such as by recording groups of data or data pairs, each group of data or data pair comprising at least one position information and at least one time information.
10

The tracking system may further comprise the at least one detector system according to the present invention. Thus, besides the at least one detector and the at least one evaluation device and the optional at least one beacon device, the tracking system may further comprise the object itself or a part of the object, such as at least one control element comprising the beacon devices or at least one beacon device, wherein the control element is directly or indirectly attachable to or integratable into the object to be tracked.
15

The tracking system may be adapted to initiate one or more actions of the tracking system itself and/or of one or more separate devices. For the latter purpose, the tracking system, preferably the track controller, may have one or more wireless and/or wire-bound interfaces and/or other types of control connections for initiating at least one action. Preferably, the at least one track controller may be adapted to initiate at least one action in accordance with at least one actual position of the object. As an example, the action may be selected from the group consisting of:
20 a prediction of a future position of the object; pointing at least one device towards the object; pointing at least one device towards the detector; illuminating the object; illuminating the detector.
25

As an example of application of a tracking system, the tracking system may be used for continuously pointing at least one first object to at least one second object even though the first object and/or the second object might move. Potential examples, again, may be found in industrial applications, such as in robotics and/or for continuously working on an article even though the article is moving, such as during manufacturing in a manufacturing line or assembly line. Additionally or alternatively, the tracking system might be used for illumination purposes, such as for continuously illuminating the object by continuously pointing an illumination source to the object even though the object might be moving. Further applications might be found in communication systems, such as in order to continuously transmit information to a moving object by pointing a transmitter towards the moving object.
30
35

The proposed devices and methods provide a large number of advantages over known detectors of this kind. Thus, the detector generally may avoid the shortcomings of the known prior art systems disclosed above. Specifically, the detector may avoid the use of FiP sensors, thereby allowing for e.g. using simple and cheap and commercially available semiconductor sensors such as silicon photodiodes. These photodiodes generally do not show a luminance dependen-
40

cy, and the method disclosed above is generally independent from the brightness of the scenery and/or the brightness of the light spot on the light beam. Consequently, a range of measurement in terms of luminance or total power of the light beam entering the detector is generally larger in the present invention as compared to many of the devices disclosed above. Further, the measurement by using the detector according to the present invention is generally independent from the target spot size, i.e. from either the size of the object, the size of a light spot projected onto the object or the size of a beacon device being one or more of attached to the object, integrated into the object or held by the object.

The detector according to the present invention may be realized as a simple device combining the functionality of distance measurement or measurement of z-coordinates, with the additional option of measuring transversal coordinates, thereby integrating the functionality of a PSD.

The result of the measurement, i.e. the position determined by the detector such as the at least one longitudinal coordinate, may be rendered widely independent from the brightness of the scenery and/or the brightness of the object, the brightness of the at least one Beacon device, the brightness of the at least one illumination source or the total power of the light beam propagating from the object to the detector. Further, due to this independence and wide range of measurement in terms of brightness, reflective objects or non-reflective objects may be used.

When mentioning a range of measurement, the range of measurement may both refer to a range of brightness which may be used with the detector according to the present invention, such as a range of total powers of the light beam, or may refer to a range of distances between the detector and the object which may be measured. Conventional detectors, such as according to one or more of the documents listed above, are typically limited in both ranges of measurement. The use of the quotient signal, as mentioned above, contrarily, provides a wide range of a continuously and monotonously decreasing or increasing function which may be used to determine the longitudinal coordinate from the quotient signal. Consequently, a very wide range of measurement in terms of distance between the object and the detector is given. Similarly, due to the general independence of the quotient signal from the total power of the light beam, at least as long as no saturation of one or both of the optical sensors is reached, also a very wide range of measurement in terms of brightness may be provided, i.e. in terms of total power of the light beam.

Overall, in the context of the present invention, the following embodiments are regarded as preferred:

Embodiment 1: A detector for determining a position of at least one object, the detector having

- at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different spatial offsets, wherein each optical sensor is configured to generate a sensor signal

in response to an illumination of its respective light-sensitive area by a light beam propagating from the object to the detector; and

- at least one evaluation device being configured for determining at least one longitudinal coordinate z of the object by combining the at least two sensor signals.

5

Embodiment 2: The detector according to the preceding embodiment, wherein the optical sensors are located in the same plane.

10

Embodiment 3: The detector according to any one of the preceding embodiments, wherein the optical sensors are partial diodes of a segmented diode, with a center of the segmented diode being off-centered from the optical axis of the detector.

15

Embodiment 4: The detector according to any one of the preceding embodiments, wherein the optical sensors are part of a sensor array, such as an array comprising 2-4 optical sensors such as a quadrant photodiode.

20

Embodiment 5: The detector according to the preceding embodiment, wherein a geometrical center of the sensor array is offset from the optical axis.

Embodiment 6: The detector according to any one of the two preceding embodiments, wherein the sensor array is movable, preferably automatically, relative to the optical axis.

25

Embodiment 7: The detector according to the preceding embodiment, wherein the evaluation device is configured for, firstly, determining the at least one transversal position of a light spot generated by the light beam on the sensor array by using the sensor signals and for, secondly, moving the sensor array relative to the optical axis until the light spot is off-centered.

30

Embodiment 8: The detector according to any one of the preceding embodiments, wherein the optical sensors are partial diodes of a quadrant diode, with a geometrical center of the quadrant diode being off-centered from the optical axis of the detector.

Embodiment 9: The detector according to any one of the preceding embodiments, wherein the light-sensitive areas of the optical sensors are equal.

35

Embodiment 10: The detector according to any one of the preceding embodiments, wherein the detector comprises at least one lens, wherein the optical axis of the detector is an axis of symmetry of the lens.

40

Embodiment 11: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for deriving the quotient signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, $A1$ and $A2$ are areas of the beam profile at the sensor position, and $E(x,y,z_o)$ denotes the beam profile given at the object distance z_o .

Embodiment 12: The detector according to the preceding embodiment, wherein the light-

5 sensitive areas are arranged such that a first sensor signal comprises information of a first area of the beam profiles and a second sensor signal comprises information of a second area of the beam profile, wherein the first area of the beam profile and the second area of the beam profile are one or both of adjacent or overlapping regions.

10 Embodiment 13: The detector according to the preceding embodiment, wherein the evaluation device is configured to determine the first area of the beam profile and the second area of the beam profile, wherein the first area of the beam profile comprises essentially edge information of the beam profile and the second area of the beam profile comprises essentially center information of the beam profile, wherein the edge information comprises information relating to a
15 number of photons in the first area of the beam profile and the center information comprises information relating to a number of photons in the second area of the beam profile.

Embodiment 14: The detector according to any one of the three preceding embodiments,

20 wherein the light beam propagating from the object to the detector illuminates the optical sensors with at least one line pattern, wherein $A1$ corresponds to an area with a full line width of the line pattern on the optical sensors, wherein $A2$ is a central area of the line pattern on the optical sensors.

Embodiment 15: The detector according to any one of the three preceding embodiments,

25 wherein the light beam propagating from the object to the detector illuminates the sensor element with at least one point pattern, wherein $A1$ corresponds to an area with a full radius of a point of the point pattern on the optical sensors, wherein $A2$ is a central area of the point on the point pattern on the optical sensors.

30 Embodiment 16: The detector according to any one of the preceding embodiments, wherein the evaluation device is configured for deriving a quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals, and wherein the evaluation device is further configured for determining the longitudinal coordinate by evaluating the quotient signal Q .

35 Embodiment 17: The detector according to the preceding embodiment, wherein the evaluation device is configured for using at least one predetermined relationship between the quotient signal Q and the longitudinal coordinate.

40 Embodiment 18: The detector according to the preceding embodiment, wherein the predetermined relationship is one or more of an empiric relationship, a semi-empiric relationship and an analytically derived relationship.

Embodiment 19: The detector according to any one of the two preceding embodiments, wherein the evaluation device comprises at least one data storage device for storing the predetermined relationship.

- 5 Embodiment 20: The detector according to any one of the four preceding embodiments, wherein the evaluation device comprises at least one divider, wherein the divider is configured for deriving the quotient signal.

- 10 Embodiment 21: The detector according to the preceding embodiment, wherein the divider is fully or partially embodied as one or both of a software divider or a hardware divider.

Embodiment 22: The detector according to any one of the preceding embodiments, wherein the optical sensors are arranged in one and the same beam path of the detector.

- 15 Embodiment 23: The detector according to any one of the preceding embodiments, wherein the optical sensors each are semiconductor sensors, preferably inorganic semiconductor sensors, more preferably photodiodes and most preferably silicon photodiodes.

- 20 Embodiment 24: The detector according to any one of the preceding embodiments, wherein the optical sensors each are uniform sensors having a single light-sensitive area each.

- 25 Embodiment 25: The detector according to any one of the preceding embodiments, wherein the optical sensors each have, at least within a range of measurement, a linear signal characteristic such that the sensor signals are dependent on the total power of illumination of the respective optical sensor and are independent from a diameter of a light spot of the illumination.

- 30 Embodiment 26: The detector according to any one of the preceding embodiments, wherein the detector further comprises an illumination source for illuminating the object, e.g., an illumination source comprising at least one laser, such as an illumination source providing at least one illuminating light beam being on the optical axis or being not on the optical axis.

- 35 Embodiment 27: The detector according to the preceding embodiment, wherein the illumination source is configured for generating an illuminating light beam for illuminating the object, wherein the detector is configured such that the illuminating light beam propagates from the detector towards the object along an optical axis of the detector.

- 40 Embodiment 28: The detector according to the preceding embodiment, wherein the detector comprises at least one reflective element, preferably at least one prism, for deflecting the illuminating light beam onto the optical axis.

- 45 Embodiment 29: The detector according to any one of the three preceding embodiments, wherein the illumination source is adapted to generate at least one illumination pattern for illumination of the object, wherein the illumination pattern comprises at least one pattern selected from the group consisting of: at least one point pattern; at least one pattern comprising at least one pre-known feature; at least one line pattern comprising at least one line; at least one line pattern comprising at least two lines such as parallel or crossing lines.

Embodiment 30: The detector according to any one of the preceding embodiments, wherein the detector further comprises at least one transfer device, the transfer device being adapted to guide the light beam onto the optical sensors.

5

Embodiment 31: The detector according to the preceding embodiment, wherein the transfer device comprises one or more of: at least one lens, preferably at least one focus-tunable lens; at least one beam deflection element, preferably at least one mirror; at least one diffractive optical element; at least one Fresnel lens; at least one beam splitting element, preferably at least one of a beam splitting cube or a beam splitting mirror; at least one multi-lens system.

10

Embodiment 32: The detector according to any one of the preceding embodiments, wherein the detector comprises the at least one illumination source, wherein the illumination source is adapted to illuminate the object with at least one illumination light beam, wherein the illumination source is arranged such that a direction of propagation of the illumination light beam is essentially parallel to the optical axis.

15

Embodiment 33: The detector according to any one of the preceding embodiments, wherein the detector comprises the at least one illumination source, wherein the illumination source and the optical axis are separated by a small baseline.

20

Embodiment 34: A detector system for determining a position of at least one object, the detector system comprising at least one detector according to any one of the preceding embodiments, the detector system further comprising at least one beacon device adapted to direct at least one light beam towards the detector, wherein the beacon device is at least one of attachable to the object, holdable by the object and integratable into the object.

25

Embodiment 35: A human-machine interface for exchanging at least one item of information between a user and a machine, wherein the human-machine interface comprises at least one detector system according to the preceding embodiment, wherein the at least one beacon device is adapted to be at least one of directly or indirectly attached to the user and held by the user, wherein the human-machine interface is designed to determine at least one position of the user by means of the detector system, wherein the human-machine interface is designed to assign to the position at least one item of information.

30

35

Embodiment 36: An entertainment device for carrying out at least one entertainment function, wherein the entertainment device comprises at least one human-machine interface according to the preceding embodiment, wherein the entertainment device is designed to enable at least one item of information to be input by a player by means of the human-machine interface, wherein the entertainment device is designed to vary the entertainment function in accordance with the information.

40

Embodiment 37: A tracking system for tracking a position of at least one movable object, the tracking system comprising at least one detector system according to any one of the preceding

embodiments referring to a detector system, the tracking system further comprising at least one track controller, wherein the track controller is adapted to track a series of positions of the object at specific points in time.

5 Embodiment 38: A scanning system for determining a depth profile of a scenery, the scanning system comprising at least one detector according to any of the preceding embodiments referring to a detector, the scanning system further comprising at least one illumination source adapted to scan the scenery with at least one light beam.

10 Embodiment 39: A camera for imaging at least one object, the camera comprising at least one detector according to any one of the preceding embodiments referring to a detector.

Embodiment 40: A readout device for optical storage media, the readout device comprising at least one detector according to any one of the preceding embodiments referring to a detector.

15 Embodiment 41: A method for determining a position of at least one object by using at least one detector, the method comprising the following steps:

- providing at least two optical sensors, each optical sensor having a light-sensitive area, wherein each light-sensitive area has a geometrical center, wherein the geometrical centers of the optical sensors are spaced apart from an optical axis of the detector by different separations, wherein each optical sensor is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area by a light beam;
- 20 - illuminating the at least two light-sensitive areas of the at least two optical sensors of the detector with a light beam propagating from the object to the detector and, thereby, generating at least two sensor signals; and
- 25 - evaluating the sensor signals by combining the at least two sensor signals, thereby determining at least one longitudinal coordinate z of the object.

30 Embodiment 42: The method according to the preceding embodiment, wherein evaluating of the sensor signals comprises deriving a quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals, and wherein the determining of the longitudinal coordinate comprises evaluating the quotient signal Q .

35 Embodiment 43: A use of the detector according to any one of the preceding embodiments relating to a detector, for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; an optical data storage application; a security application; a surveillance application; a safety application; a human-machine interface application; a tracking application; a photography application; a logistics application; a machine vision application; a robotics application; a quality control application; a manufacturing application; a use for calibration of a distance measurement; a use in combination with optical data storage and readout.

40

Brief description of the figures

Further optional details and features of the invention are evident from the description of preferred exemplary embodiments which follows in conjunction with the dependent claims. In this context, the particular features may be implemented in an isolated fashion or in combination with other features. The invention is not restricted to the exemplary embodiments. The exemplary embodiments are shown schematically in the figures. Identical reference numerals in the individual figures refer to identical elements or elements with identical function, or elements which correspond to one another with regard to their functions.

Specifically, in the figures:

Figures 12A and B show embodiments of determining a longitudinal coordinate z using a line pattern; and

Figures 13A and B show further embodiments of the detector according to the present invention comprising at least one bi-cell.

Detailed description of the embodiments

In Fig. 1, a schematic view of a first embodiment of a detector 110 for determining a position of at least one object 112 is depicted. In this case, the object 112 comprises a beacon device 114, from which a light beam 116 propagates towards a first optical sensor 118 and a second optical sensor 120. The first optical sensor 118 comprises a first light-sensitive area 122, and the second optical sensor 120 comprises a second light-sensitive area 124. The optical sensors 118, 120, as shown e.g. in Fig. 4, may be part of an array 174 of optical sensors 176, such as the first optical sensor 118 being the optical sensor 176 in the upper left corner of the array 174 and the second optical sensor 120 being the optical sensor 176 in the lower right corner of the array 174. Other choices are feasible. The array 174, as an example, may be a quadrant photodiode 178, and the optical sensors 176 may be partial diodes of the quadrant photodiode 178.

The light beam 116, as an example, may propagate along an optical axis 126 of the detector 110. Other embodiments, however, are feasible. The optical detector 110, further, may comprise at least one transfer device 128, such as at least one lens or a lens system, specifically for beam shaping. Consequently, the light beam 116 is focused, such as in one or more focal points 130, and a beam width of the light beam 116 may depend on a longitudinal coordinate z of the object 112, such as on a distance between the detector 110 and the beacon device 114 and/or the object 112. For details of this beam width dependency on the longitudinal coordinate, reference may be made to one or more of the above-mentioned prior art documents, such as to one or more of WO 2012/110924 A1 and/or WO 2014/097181 A1.

As can be seen in Fig. 4, the setup of the detector 110 is off-centered in various ways. Thus, a geometrical center 180 of the array 174 may be off-centered from the optical axis 126 by offset d_0 . Further, a geometrical center 182 of the first optical sensor 118 is off-centered from the optical axis 126 by offset d_1 , and a geometrical center 184 of the second optical sensor 120 is off-centered from the optical axis 126 by offset d_2 , wherein $d_1 \neq d_2$. In other words, a light spot 186 is formed, which is unequally distributed over the light-sensitive areas 122, 124.

As will be shown in further detail below, the detector 110 may be configured for automatically establishing the off-centered position of the light spot 186 on the array 174. For this purpose, firstly, the detector 110 may be configured for determining whether the sensor signals generated by the optical sensors 176 of the array 174 are equal. If this should be the case, the detector 110 may be configured to determine that the light spot 186 is centered in the array 174 and, consequently, may shift the light spot 186 out of the geometrical center 180 of the array 174, such as by shifting the whole array 174 in a plane perpendicular to the optical axis 126. For this

purpose, as will be shown in further detail below with respect to Fig. 3, one or more actuators may be provided in the detector 110.

Turning back to the setup of Fig. 1, the first optical sensor 118, in response to the illumination by the light beam 116, generates a first sensor signal s_1 , whereas the second optical sensor 120 generates a second sensor signal s_2 . Preferably, the optical sensors 118, 120 are linear optical sensors, i.e. the sensor signals s_1 and s_2 each are solely dependent on the total power of the light beam 116 or of the portion of the light beam 116 illuminating their respective light-sensitive areas 122, 124, whereas these sensor signals s_1 and s_2 are independent from the actual size of the light spot of illumination. In other words, preferably, the optical sensors 118, 120 do not exhibit the above-described FiP effect.

The sensor signals s_1 and s_2 are provided to an evaluation device 132 of the detector 110. The evaluation device 110, as symbolically shown in Fig. 1, may specifically be embodied to derive a quotient signal Q , as explained above. The quotient signal Q , derived by dividing the sensor signals s_1 and s_2 or multiples or linear combinations thereof, may be used for deriving at least one item of information on a longitudinal coordinate z of the object 112 and/or the beacon device 114, from which the light beam 116 propagates towards the detector 110, as will be explained in further detail with reference to the corrosion signals shown in Fig. 6 to 8 below.

The detector 110, in combination with the at least one beacon device 114, may be referred to as a detector system 134, as will be explained in further detail below with reference to Fig. 3.

In Fig. 2, a modification of the embodiment of Fig. 1 is shown, which forms an alternative detector 110. The alternative embodiment of the detector 110 widely corresponds to the embodiment shown in Fig. 1. Instead of using an active light source, i.e. a beacon device 114 with light-emitting properties for generating the light beam 116, however, the detector 110 comprises at least one illumination source 136. The illumination source 136, as an example, may comprise a laser, whereas, in Fig. 1, as an example, the beacon device 114 may comprise a light-emitting diode (LED). The illumination source 136 may be configured for generating at least one illumination light beam 138 for illuminating the object 112. The illumination light beam 138 is fully or partially reflected by the object 112 and travels back towards the detector 110, thereby forming the light beam 116. The illumination source 136, as an example, may comprise one or more diaphragms 190, such as an adjustable diaphragm 190, e.g. an adjustable iris diaphragm and/or a pin hole.

The setup shown in Fig. 2, as an example, may also be used in or as a readout device 192 for optical storage media. Thus, as an example, the object 112 may be an optical storage medium such as in optical storage discs, e.g. a CCD, DVD or Blu-ray disc. By measuring the presence or non-presence of data storage modules and the depth of the same within the object 112, by using the above-mentioned measurement principle, a data readout may take place.

The light beam 116, specifically, may travel along the optical axis 126 of the detector 110. As shown in Fig. 2, as an example, the illumination light beam 138 may be parallel to the optical axis 126 of the detector 110. Other embodiments, i.e. off-axis illumination and/or illumination at an angle, are feasible, too, as will be shown in the context of Fig. 9A and 9B below. In order to provide an on-axis illumination, as shown in Fig. 2, as an example, one or more reflective elements 140 may be used, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms.

Apart from these modifications, the setup of the embodiment in Fig. 2 corresponds to the setup in Fig. 1. Thus, again, an evaluation device 132 may be used, having, e.g., at least one divider 142 for forming the quotient signal Q, and, as an example, at least one position evaluation device 144, for deriving the at least one longitudinal coordinate z from the at least one quotient signal Q. It shall be noted that the evaluation device 132 may fully or partially be embodied in hardware and/or software. Thus, as an example, one or more of components 142, 144 may be embodied by appropriate software components.

It shall further be noted that the embodiments shown in Fig. 1 and 2 simply provide embodiments for determining the longitudinal coordinate z of the object 112. It is also feasible, however, to modify the setups of Fig. 1 and 2 to provide additional information on a transversal coordinate of the object 112 and/or of parts thereof. As an example, e.g. in between the transfer device 128 and the optical sensors 118, 120, one or more parts of the light beam 116 may be branched off, and may be guided to a position-sensitive device such as one or more CCD and/or CMOS pixelated sensors and/or additional quadrant detectors and/or other position sensitive devices, which, from a transversal position of a light spot generated thereon, may derive a transversal coordinate of the object 112 and/or of parts thereof. For further details, as an example, reference may be made to one or more of the above-mentioned prior art documents which provide for potential solutions of transversal sensors.

Fig. 3 shows, in a highly schematic illustration, an exemplary embodiment of a detector 110, e.g. according to the embodiments shown in Fig. 1 or 2. The detector 110 specifically may be embodied as a camera 146 and/or may be part of a camera 146. The camera 146 may be made for imaging, specifically for 3D imaging, and may be made for acquiring standstill images and/or image sequences such as digital video clips. Other embodiments are feasible.

Fig. 3 further shows an embodiment of a detector system 134, which, besides the at least one detector 110, comprises one or more beacon devices 114, which, in this example, may be attached and/or integrated into an object 112, the position of which shall be detected by using the detector 110. Fig. 3 further shows an exemplary embodiment of a human-machine interface 148, which comprises the at least one detector system 134 and, further, an entertainment device 150, which comprises the human-machine interface 148. The figure further shows an embodiment of a tracking system 152 for tracking a position of the object 112, which comprises the detector system 134. The components of the devices and systems shall be explained in further detail below.

Fig. 3 further shows an exemplary embodiment of a scanning system 154 for scanning a scenery comprising the object 112, such as for scanning the object 112 and/or for determining at least one position of the at least one object 112. The scanning system 154 comprises the at least one detector 110, and, further, optionally, the at least one illumination source 136 as well as, optionally, at least one further illumination source 136. The illumination source 136, generally, is configured to emit at least one illumination light beam 138, such as for illumination of at least one dot, e.g. a dot located on one or more of the positions of the beacon devices 114 and/or on a surface of the object 112. The scanning system 154 may be designed to generate a profile of the scenery including the object 112 and/or a profile of the object 112, and/or may be designed to generate at least one item of information about the distance between the at least one dot and the scanning system 154, specifically the detector 110, by using the at least one detector 110.

As outlined above, an exemplary embodiment of the detector 110 which may be used in the setup of Fig. 3 is shown in Fig. 1 and 2 or will be shown, as an alternative embodiment, in Fig. 5 below. Thus, the detector 110, besides the optical sensors 118, 120, comprises at least one evaluation device 132, having e.g. the at least one divider 142 and/or the at least one position evaluation device 144, as symbolically depicted in Fig. 3. The components of the evaluation device 132 may fully or partially be integrated into a distinct device and/or may fully or partially be integrated into other components of the detector 110. Besides the possibility of fully or partially combining two or more components, one or more of the optical sensors 118, 120 and one or more of the components of the evaluation device 132 may be interconnected by one or more connectors 156 and/or by one or more interfaces, as symbolically depicted in Fig. 5. Further, the one or more connectors 156 may comprise one or more drivers and/or one or more devices for modifying or preprocessing sensor signals. Further, instead of using the at least one optional connector 156, the evaluation device 132 may fully or partially be integrated into one or both of the optical sensors 118, 120 and/or into a housing 158 of the detector 110. Additionally or alternatively, the evaluation device 132 may fully or partially be designed as a separate device.

In Fig. 3, as an example, one or more reflective elements 140 may be used, for example partially transparent, such as one or more prisms and/or mirrors, such as dichroitic mirrors, such as movable mirrors or movable prisms.

The detector 110 as symbolically shown in the exemplary embodiment of Fig. 3 may also comprise at least one actuator 188 for moving the array 174 of the optical sensors 176 relative to the optical axis 126. As outlined above, for providing this movement, the optical axis 126 may be moved in relation to the array 174 by moving the optical axis 126, by moving the array 174 or both. Thus, as an example, the optical axis may be moved by using one or more of deflecting elements and/or by using the transfer device 128. As a simple example, a lens of the transfer device 128 may be tilted, such as by using one or more actuators 188 (not depicted). Additionally or alternatively, the array 174 may be shifted by the one or more actuators 188, preferably in a plane perpendicular to the optical axis 126. As an example, one or more electromechanical actuators may be used, such as one electromechanical actuator for an x-direction and another

electromechanical actuator for a y-direction. Other embodiments are feasible. Thereby, the above-mentioned off-centering procedure may be implemented for establishing an off-centered situation as shown e.g. in Fig. 4.

5 In the exemplary embodiment shown in Fig. 3, further, the object 112, the position of which may be detected, may be designed as an article of sports equipment and/or may form a control element or a control device 160, the position of which may be manipulated by a user 162. As an example, the object 112 may be or may comprise a bat, a racket, a club or any other article of sports equipment and/or fake sports equipment. Other types of objects 112 are possible. Further, the user 162 himself or herself may be considered as the object 112, the position of which shall be detected.

As outlined above, the detector 110 comprises at least the optical sensors 176, including at least the first optical sensor 118 and the second optical sensor 120. The optical sensors 176
15 may be located inside the housing 158 of the detector 110. Further, the at least one transfer device 128 may be comprised, such as one or more optical systems, preferably comprising one or more lenses.

An opening 164 inside the housing 158, which, preferably, is located concentrically with regard to the optical axis 126 of the detector 110, preferably defines a direction of view 166 of the detector 110. A coordinate system 168 may be defined, in which a direction parallel or anti-parallel to the optical axis 126 may be defined as a longitudinal direction, whereas directions perpendicular to the optical axis 126 may be defined as transversal directions. In the coordinate system 128, symbolically depicted in Fig. 5, a longitudinal direction is denoted by z, and transversal directions are denoted by x and y, respectively. Other types of coordinate systems 168 are feasible, such as non-Cartesian coordinate systems.

The detector 110 may comprise the optical sensors 118, 120 as well as, optionally, further optical sensors. The optical sensors 118, 120 preferably are located in one and the same beam path, one behind the other, such that the first optical sensor 118 covers a portion of the second optical sensor 120. Alternatively, however, a branched beam path may be possible, with additional optical sensors in one or more additional beam paths, such as by branching off a beam path for at least one transversal detector or transversal sensor for determining transversal coordinates of the object 112 and/or of parts thereof.

35 One or more light beams 116 are propagating from the object 112 and/or from one or more of the beacon devices 114, towards the detector 110. The detector 110 is configured for determining a position of the at least one object 112. For this purpose, as explained above in the context of Fig. 1, 2 and 4, the evaluation device 132 is configured to evaluate sensor signals provided
40 by the optical sensors 118, 120. The detector 110 is adapted to determine a position of the object 112, and the optical sensors 118, 120 are adapted to detect the light beam 116 propagating from the object 112 towards the detector 110, specifically from one or more of the beacon devices 114. In case no illumination source 136 is used, the beacon devices 114 and/or at least

one of these beacon devices 114 may be or may comprise active beacon devices with an integrated illumination source such as a light-emitting diode. In case the illumination source 136 is used, the beacon devices 114 do not necessarily have to be active beacon devices. Contrarily, a reflective surface of the object 112 may be used, such as integrated reflective beacon devices 114 having at least one reflective surface. The light beam 116, directly and/or after being modified by the transfer device 128, such as being focused by one or more lenses, illuminates the light-sensitive areas 122, 124 of the optical sensors 118, 120. For details of the evaluation, reference may be made to Fig. 1, 2 and 4 above.

As outlined above, the determination of the position of the object 112 and/or a part thereof by using the detector 110 may be used for providing a human-machine interface 148, in order to provide at least one item of information to a machine 170. In the embodiments schematically depicted in Fig. 3, the machine 170 may be a computer and/or may comprise a computer. Other embodiments are feasible. The evaluation device 132 may even be fully or partially integrated into the machine 170, such as into the computer.

As outlined above, Fig. 3 also depicts an example of a tracking system 152, configured for tracking the position of the at least one object 112 and/or of parts thereof. The tracking system 152 comprises the detector 110 and at least one track controller 172. The track controller 172 may be adapted to track a series of positions of the object 112 at specific points in time. The track controller 172 may be an independent device and/or may be fully or partially integrated into the machine 170, specifically the computer, as indicated in Fig. 3 and/or into the evaluation device 132.

Similarly, as outlined above, the human-machine interface 148 may form part of an entertainment device 150. The machine 170, specifically the computer, may also form part of the entertainment device 150. Thus, by means of the user 162 functioning as the object 112 and/or by means of the user 162 handling a control device 160 functioning as the object 112, the user 162 may input at least one item of information, such as at least one control command, into the computer, thereby varying the entertainment functions, such as controlling the course of a computer game.

In the setup of the detectors 110 as shown in Fig. 1, 2 and 3, the optical sensors 176 are part of an array 174, and all optical sensors 176 may be located in one and the same plane oriented essentially perpendicular to the optical axis 126. As noted in this context, when mentioning “perpendicular” or “essentially perpendicular”, preferably, a 90° orientation is given. However, tolerances may be present, such as angular tolerances of no more than 20°, preferably of no more than 10° or more preferably of no more than 5°. The optical sensors 176, however, not necessarily have to be located in an array 174 and not necessarily have to be located in one and the same plane, as is shown in an alternative setup of the detector 110 shown in Fig. 5. In this figure, only the optical components are shown. For other components, reference may be made to Fig. 1, 2 and 3 above.

As can be seen, in this alternative setup, two or more optical sensors 176 are present, comprising at least one first optical sensor 118 and at least one second optical sensor 120 located in different planes which are offset in a direction of the optical axis 126, also referred to as the z-direction. Further, as can also be seen, the optical sensors 118, 120 may overlap, whereas in the previous embodiments, preferably, no overlap between the optical sensors 176 is given. Apart from these modifications, the functionality and the evaluation of the sensor signals generally corresponds to the embodiment of Fig. 1, 2 and 3 above.

As discussed above, for evaluating the at least two sensor signals of the at least two optical sensors 176 and for deriving an information on the longitudinal position of the object 112 thereof, such as a distance between the detector 110 and the object 112 and/or a z-coordinate of the object 112, preferably, at least one combined sensor signal is generated by the evaluation device 132. The combined sensor signal, as long as this combined sensor signal provides, at least over a measurement range, a unique function of the distance, may be used for deriving the longitudinal coordinate. As an example, the combined sensor signal may be or may comprise at least one quotient signal Q . In Fig. 6 to 8, quotient signals Q of two sensor signals of two optical sensors 176 are shown under various measurement conditions. In each case, the quotient signal Q is denoted on the vertical axis, as a function of the longitudinal coordinate z of the object 112 on the horizontal axis, the latter given in centimeters.

In all experiments, a setup as shown in Fig. 2 was used. As an illumination source 136, in the experiments of Fig. 6 and 7, a 980 nm Picotronic laser source was used, in conjunction with a lens having a focal length of 100 mm. In the experiment of Fig. 8, a Laser Components laser light source having a wavelength of 850 nm was used, in conjunction with a lens having a focal length of 79 mm. In all experiments, the laser beam was aligned on the optical axis 126 via a small prism in front of the lens 128, forming a reflective element 140. A diaphragm 190 in front of the laser source was used to vary the spot size. The quadrant diode 178 was used to measure the reflection of the laser source on different materials. In all experiments, the distance dependency is given by the quotient Q of two adjacent quadrant currents.

In Fig. 6, the laser power was varied during the experiment, from 8 nA laser current, denoted by the dotted line, to 106 nA, denoted by the solid line. Therein, since the laser current typically does not provide a measure for the laser intensity, the laser current indicated therein is a current of a silicon photodetector in a measurement setup in which the laser illuminates a white sheet of paper at a distance of 330 mm from the lens. As is clearly visible, the curves are nearly identical and, at least within this range of variation of the laser power, do not significantly depend on the laser power. This experiment shows that the quotient signal provides a reliable and monotonous function of the longitudinal coordinate, independent from the influence of the brightness of the illumination source.

In Fig. 7, a spot size of the illumination source 136 was varied, by varying the open diameter of the diaphragm 190 in front of the laser. The spot size was varied from 1.5 mm, denoted by the dotted line, to 3.5 mm, denoted by the solid line, in steps of 0.5 mm. As can be seen, up to a

distance of approximately 200 cm, the quotient signal Q does not depend on the spot size and, thus, again, is not negatively affected by this variation.

In Fig. 8, a material of the object 112 illuminated by the laser beam was varied. Therein, the dotted line denotes white paper, the dashed line with the smallest dashes denotes black paper, the dashed line with the medium dashes denotes wood, and the dashed line with the largest dashes denotes an aluminum plate. As can be seen, at least up to a measurement range of approximately 250 cm, the experiment does not strongly depend on the type of material used for the object 112.

The experiments shown in Fig. 6 to 8, thus, clearly demonstrate that the quotient signal Q provides a reliable function of the distance. At least within a range of measurement, the function monotonously rises with the distance. The function is not strongly influenced by the most significant variations which may occur in real life measurements, such as the brightness of the illumination source, the spot size of the illumination source or the material of the object 112. Thus, by evaluating the quotient signal Q of two or more optical sensors 176, reliable distance information may be generated. Thus, as an example, the curves shown in Fig. 6 to 8 directly may be used as calibration curves for the purpose of the evaluation device 132. Other evaluation methods, however, are feasible.

In Fig. 9A and 9B, an alternative embodiment of the detector 110 is shown which is a modification of the setup shown in Fig. 2. Thus, for most elements and optional details as well as further elements not shown in the schematic Figures 9A and 9B, reference may be made to the description of Fig. 2 above.

In Figure 2, the illumination light beam 138, as discussed above, preferably travels along the optical axis 126, i.e. parallel to the optical axis 126 or even on the optical axis 126. In the setup, the position of the center of the light spot 186 typically does not depend on the z-coordinate of the object 112, such as on a distance between the object 112 and the detector 110. In other words, the diameter or equivalent diameter of the light spot 186 changes with the distance between the object 112 and the detector 110 whereas, typically, the position of the light spot 186 on the array 174 does not.

Contrarily, in Fig. 9A and 9B, a setup of the detector 110 is shown in which an illumination light beam 138 travels off-axis, i.e. one or both of at an angle other than 0° with the optical axis 126 or parallel to the optical axis 126 but shifted from the optical axis 126. This embodiment, as will be discussed in further detail below, demonstrates that the method according to the present invention can be further enhanced by increasing the z-dependency of a combined sensor signal. Thus, in Fig. 9A, a side view is shown with two different positions of the object 112, i.e. a first position at z_1 , drawn in solid lines, and a second position at z_2 , drawn in dashed lines. As can be seen, the illumination light beam 138 which, as an example, propagates at an angle of 5° to 30° , e.g. 10° to 20° , with the optical axis 126, hits the object 112 in both cases at different positions. From these points of the object 112 illuminated by the illumination light beam 138,

light beams 116 propagate towards the detector 110, wherein, again, the light beam 116 for the object 112 being located at position z_1 is drawn in solid lines, wherein the light beam 116 for the object 112 being located at position z_2 is drawn in dashed lines.

In Fig. 9B, the array 174, e.g. a quadrant photodiode, is shown in an enlarged fashion. As can be seen in this setup, the position of the light spot 186 moves with the longitudinal position z of the object 112. Thus, not only is the size of the light spot 186 affected by the longitudinal position z but also is the position on the array 174 of the light spot 186 changed. In Fig. 9B, this movement of the light spot 186 is denoted by arrow z .

Consequently, by this movement of the light spot 186, the z -dependency of a combined sensor signal taking into account at least two sensor signals of the optical sensors 176 may be increased. As an example, the four diodes of the array 174, in Fig. 9B, are denoted by D1-D4. The quotient signal Q , as an example, may be formed as $Q = i(D1)/i(D4)$, with $i(D1)$ being the sensor signal of photodiode D1, and $i(D4)$ being the sensor signal of photodiode D4.

As shown in Figure 9B, the quadrant diode may comprise two dividing lines. The dividing lines may be arranged orthogonal to each other. The orthogonal arrangement of the dividing lines allows adjusting of the quotient signal for near field and far field applications independently from each other. In addition to determining the quotient signal of sensor signals of two optical sensors of the quadrant diode, the evaluation device 132 may be adapted to determine a second quotient using at least three or all four sensor signals of the quadrant diode. The two quotients can be formed such that two distinct distance ranges are covered. The two quotient signals for the near field and far field may have an overlap region in which both quotients allow obtaining reasonable determination of the longitudinal distance z . For example, the quotient may be determined by $Q = i(D1+D2)/i(D3+D4)$, wherein the sensor signals of the two top quadrants, also called top segment, are divided by the sensor signals of the two bottom quadrants, also called bottom segment. Using the quotient of sensor signals determined by two sensor areas which have a dividing line parallel to the baseline of the detector may allow determining of the quotient without any distance dependent movement of the light spot. In particular, as an example, if the dividing line between top and bottom segment is parallel to the baseline, the quotient signal determined from the top segment divided by the bottom segment may be used in the near field, wherein the light spot may illuminate only one of a left or right segment of the quadrant diode. In this case determining the quotient signal by dividing sensor signals of the left and right segments may not be possible. However, determining the quotient by dividing the sensor signals of top and bottom segments may provide a reasonable distance measurement. The quotient signal determined by dividing sensor signals of the left and right segments, i.e. $Q = i(D1+D3)/i(D2+D4)$, may be used for far field measurement, wherein the light spot illuminates both left and right segments. Furthermore, the evaluation device may be adapted to determine the quotient by dividing sensor signals of opposing segments or neighboring segments. The evaluation device may be adapted to combine the acquired sensor signals $i(D1)$, $i(D2)$, $i(D3)$ and $i(D4)$ of the quadrants such that distance measurement is possible over a wide range with a large resolution.

In the situation shown in Fig. 2, the position of the light spot 186 does not depend on z . With a change in z , depending on the optical situation, the spot will become larger or smaller, such as by becoming more diffuse or more focused. In case the spot size increases and the spot be-
comes more diffuse, $i(D4)$ will increase more rapidly than $i(D1)$, such that the quotient signal Q decreases.

Contrarily, in the situation of Fig. 9A, both the size and the position of the light spot 186 are dependent on the z -coordinate. Thus, the tendency of the z -dependency of the combined sensor signal such as the quotient signal Q will be increased. In the situation of Figure 2, depending on the z -coordinate, the sensor signal of at least one sensor will increase and simultaneously the sensor signal of at least one different sensor will decrease, resulting in the z -dependent quotient signal Q . In the situation of Fig. 9A, the position dependency of the light spot 186 can result in three different situations depending on the relative position of light source, optical axis, and sensor: Firstly, the position dependency of the light spot may result in a further decrease of the at least one decreasing sensor signal depending on the z -coordinate, while, simultaneously, the position dependency of the light spot may result in a further increase of the at least one decreasing sensor signal depending on the z -coordinate compared to the situation in Figure 2. Secondly, the position dependency of the light spot may result in a reduced decrease or even increase of the at least one decreasing sensor signal depending on the z -coordinate, while, simultaneously, the position dependency of the light spot may result in a reduced increase or even decrease of the at least one decreasing sensor signal depending on the z -coordinate compared to the situation in Figure 2. Thirdly, the position dependency of the light spot may be as such that the z -dependence of the sensor signals is largely unchanged compared to the situation in Figure 2. However, according to the present invention, object distance is not determined from the position of the light spot on a sensor as done in triangulation methods. Instead, movement of the light spot 186 on the array 174 may be used to enhance dynamic of the sensor signals and or the resulting quotient signal Q which may result in an enhanced dynamic of the z -dependency.

Additionally, as known from the prior art, the sensor signals $i(D1)$, $i(D2)$, $i(D3)$, $i(D4)$ may also be used for determining a transversal position x , y of the object 112. Further, the sensor signals may also be used for verifying the z -coordinate determined by the present invention.

Figure 9C shows a comparison of two experimental setups using a detector setup according to Figure 9A with a Bi-cell as optical sensors 176 with two light sensitive areas. In a first experimental setup, depending on the relative position of the illumination light source, the optical axis and the sensor, the light spot 186 may move in parallel to the linear boundary of the two optical sensors 176 of the Bi-cell along a direction of movement 194 in dependence of the object distance. Since the direction of movement 194 of the light spot 186 is in parallel to the linear boundary of the two light sensitive areas in dependence of the object distance, the resulting sensor signals are identical to a situation with no movement of the light spot 186 depending on object distance as shown in Figure 2. In a second experimental setup, depending on the relative

position of the illumination light source, the optical axis and the sensor, the light spot 186 may move as such that the distance of the center of the light spot 186 to the boundary of the two optical sensors 176 of the Bi-cell changes in dependence of the object distance such as a movement orthogonal to the boundary of the two optical sensors 176 such as a movement
5 along a direction of movement 196 in dependence of the object distance. The detector setup allowing movement of the light spot 186 may be a modification of the setup shown in Figure 9A. Thus, for most elements and optional details as well as further elements, reference may be made to the description of Fig. 9A above. In Figure 9C, the optical sensors 176 may be a bi-cell diode.

10 Figure 9D shows experimental results of the comparison of the two experimental setups using a detector setup according to Figure 9A, allowing movement of the light spot 186 according to Figure 9C with movement of the light spot depending on the object distance along directions of movement 194 and 196. Curve 198 shows the dependency of quotient Q on the longitudinal
15 coordinate z for the detector setup allowing movement of the light spot 186 along a direction of movement 194 as shown in Figure 9C which is in parallel to the boundary of the optical sensors of the Bi-Cell and, which is a situation equivalent to Figure 2 without a movement of the light spot depending on the object distance. Curve 200 shows the dependency of quotient Q on the longitudinal coordinate z for the detector setup according to Figure 9A and using a detector set-
20 up allowing movement of the light spot 186 with movement of the light spot 186 according to Figure 9C with movement of the light spot depending on the object distance along a direction of movement 196. The experimental setup was as follows: The optical sensors 176 may be a bi-cell diode, in particular a Si-Bi-Cell. The illumination source 136 may be a 950 nm laser with a spot size of 4 mm. The transfer device 128 may have a focal length of 20 mm, e.g. a lens avail-
25 able as Thorlabs Asphere, f= 20 mm. The distance of the object 112 was varied from 0 to 3000 mm. Determination of the longitudinal coordinate z may be possible without allowing movement of the light spot 186. In particular, according to the present invention, movement of the light spot may not be essential for determination of the longitudinal coordinate z. With the detector setup allowing movement of the light spot 186 along a direction 194 or without any movement deter-
30 mination of object distance is possible at very small distance, whereas with movement along a direction 196 determination of object distance is possible for object distance such as distances greater than 500mm.

35 Figures 10A and 10B show an exemplary embodiment of a detector 110 with a small baseline 202. Figure 10A shows side view of the detector 110. The detector 110 may comprise the at least one illumination source 136. The illumination source 136 may be adapted to illuminate the object 112 with at least one illumination light beam 138. The illumination light beam 138 may be fully or partially reflected by the object and may travel back towards the optical sensor 176. The illumination source 136 may be arranged such that a direction of propagation of the illumination
40 light beam is essentially parallel to the optical axis 126. The illumination source 136 may be arranged such that a line running in the direction of propagation of the illumination light beam and the optical axis 126 do not intersect in space. The illumination source 136 and the optical axis 126 may be separated by a small baseline 202. The illumination source 136 may be

spaced apart from the optical axis 126 by a minimum distance. The minimum distance from the optical axis may be defined by further detector elements such as size and position of the optical sensors and transfer device. Figure 10B shows a front view on the illumination light beam 138 and the transfer device 128. The baseline may be less than 0,1 m, preferably less than 0,05 m, more preferably less than 0,025 m. For example, the detector 110 may be a compact device without further optical elements, wherein the illumination source 136 may be placed as close as possible to an edge of the transfer device 128. Thus, the baseline 202 may be close to half a diameter of the transfer device 128, in particular the lens diameter and housings of lens and light source. The illumination source 136 may be arranged such that the baseline 202 is as small as possible. For example, a distance from the center of the transfer device 128 to the illumination source 136, in particular along a connecting line from the center of the transfer device 128 to the illumination source 136, may be preferably less than 2.5 times a distance from the center of the transfer device 128 to an edge if the transfer device 128, more preferably less than 1.5 times the distance center to edge of the transfer device 128, and most preferably less 1 times the distance center to edge of the transfer device 128.

Figure 11 A to O show further exemplary configurations of optical sensors according to the present invention, in particular top view in direction of propagation of the light beam 116. In Figure 11A, a top view of two rectangular optical sensors is shown, wherein the first optical sensor 118 is a small optical sensor in front of a larger second optical sensor 120. The first optical sensor 118 and the second optical sensor 120 may be arranged with a different offset, in particular in a transversal direction y, from the optical axis 126. In Figures 11B and 11C, top view of a large rectangular optical sensor 120 is shown, wherein the first optical sensor 118 is a small optical sensor in front of a larger second optical sensor 120 having a triangle shaped (Figure 11B) or star-shaped (Figure 11C) light-sensitive area. Alternatively, the first optical sensor 118 and the second optical sensor 120 may be located at the same longitudinal coordinate, such as in the same plane, such as as separated light sensitive elements.

In Figures 11 M to O, a top view of two rectangular optical sensors is shown, wherein the first optical sensor 118 and the second optical sensor 120 are rectangular sensors with the same size. In Figures 11 M to O a mask 119 is arranged in front of the first and second optical sensors 118, 120. The mask 119 may be arranged with a different offset from the optical axis 126. The mask 119 may have an arbitrary size and shape, for example, the mask may be rectangular shaped (Figure 11M), triangle shaped (Figure 11N) or star-shaped (Figure 11O). However, other sizes and shapes are feasible. Mask 119 may be adapted to prevent light impinging on the light sensitive areas of the first and second optical sensors 118, 120.

Alternatively to using a mask 119, Figures 11 M to O may be understood as a first optical sensor 118a having rectangular shape (Figure 11M), triangle shape (Figure 11N) or cross-shape or star-shape (Figure 11O) and yielding a first sensor signal and a second optical sensor 120a yielding a second sensor signal, wherein the second optical sensor 120a may be separated into several light sensitive areas, for example four light sensitive areas 121a.

The geometrical centers of the first optical sensor 118 and the second optical sensor 120 are spaced apart from the optical axis 126 of the detector 110. Figure 11K shows two circular shaped optical sensors, wherein the first optical sensor 118 is a small optical sensor in front of the larger second optical sensor 120. Alternatively, the first optical sensor 118 and the second optical sensor 120 may be located at the same longitudinal coordinate, such as in the same plane, such as as separated light sensitive elements. In Figures 11D, the light sensitive area of the first optical sensor 118 is square-shaped, and the light sensitive area of the second optical sensor 120 is rectangular, such that the surface areas in x and y differ. In addition, a center of the first optical sensor 118 and a center of second optical sensor 120 may have different x coordinates such that the optical sensors 118, 120 may have different spatial offset in one or more of x and y direction from the optical axis. In Figure 11H, both the first optical sensor 118 and the second optical sensor 120 may be rectangular. The first optical sensor 118 and the second optical sensor 120 may be arranged such that the center of the first optical sensor 118 and the center of second optical sensor 120 may have different x coordinates and that the surface areas in x and y differ. In Figure 11L, the first optical sensor 118 may have a deviating shape from the shape of the second optical sensor 120 such as a circular or semicircular shape. Figures 11 E, F, G, I, J show a matrix 115 comprising a plurality of partial diodes. In Figures 11 E, F, G the matrix 115 has a rectangular shape, whereas in Figures 11 I and J the matrix 115 has a circular shape. Rows and columns may be arranged equidistant or non-equidistant. In case of equidistant rows and/or columns the matrix 115 may be arranged with a spatial offset to the optical axis 126. The sensor signals of the light sensitive areas of the matrix 115 in Figure 11 E, F, G, I, J may be summarized such as added to form a first sensor signal of a first optical sensor and a second sensor signal of a second optical sensor. As an example, the sensor signals of the light sensitive areas in the corners of the sensor element 115 in Figure 11 G may be added to form a first sensor signal, whereas the remaining light sensitive areas of the sensor element 115 may be added to form a second sensor signal.

Referring to Figures 12A and B, the detector 110 such as the detector as described with respect to Figures 1 to 11 may be adapted to determine depth information, in particular absolute depth information, from a radiance ratio of at least two asymmetric regions of a light beam profile on the at least two optical sensors 118, 120. For example, the detector 110 may comprise a plurality of optical sensors. The detector 110 may be adapted to determine depth information from a radiance ratio of at least two asymmetric regions within an enclosed, in particular, defocused beam profile captured by the at least two optical sensors 118, 120. In one embodiment, the light beam 116 may illuminate the at least two optical sensors 118, 120 with at least one pattern comprising at least one feature point. The feature point may be selected from the group consisting of: at least one point, at least one line, at least one edge. The pattern may be generated by the object, for example, in response to an illumination by the at least one light source with an illumination pattern comprising the at least one pattern. The evaluation device 132 may be configured for deriving the quotient signal Q by

$$Q(z_o) = \frac{\iint_{A_1} E(x, y; z_o) dx dy}{\iint_{A_2} E(x, y; z_o) dx dy}$$

wherein x and y are transversal coordinates, A1 and A2 are areas of the beam profile at the sensor position, and E(x,y,z_o) denotes the beam profile given at the object distance z_o. A1 may correspond to a full or complete area of a feature point on the optical sensors. A2 may be a central area of the feature point on the optical sensors 118, 120. The central area may be a constant value. The central area may be smaller compared to the full area of the feature point. For example, in case of a circular feature point, the central area may have a radius from 0.1 to 0.9 of a full radius of the feature point, preferably from 0.4 to 0.6 of the full radius.

In the embodiment shown in Figure 41 A, the light beam 116 propagating from the object 112 to the detector 110 may illuminate the at least two optical sensors 118, 120 with at least one line pattern 2186. The line pattern 204 may be generated by the object 112, for example in response to an illumination by the at least one illumination source with an illumination pattern comprising at least one illumination line pattern. A1 may correspond to an area with a full line width of the line pattern 204. The line pattern 204 on the at least two optical sensors 118, 120 may be widened and/or displaced compared to the line pattern of the illumination pattern such that a line width on the at least two optical sensors 118, 120 is increased. A2 may be a central area of the line pattern 204 on the at least two optical sensors 118, 120. The line width of the central area may be a constant value, and may in particular correspond to the line width in the illumination pattern. The central area may have a smaller line width compared to the full line width. For example, the central area may have a line width from 0.1 to 0.9 of the full line width, preferably from 0.4 to 0.6 of the full line width. Figure 12B show an embodiment, wherein the detector 110 may comprise at least two rows of optical sensors 118, 120, wherein the rows are arranged on top of each other. The line pattern 204 may be imaged parallel to the rows such that the center of the line pattern is fixed or moves only little relative to a dividing line 206 of the rows. The A1 may correspond to an area above the dividing line 206 and A2 may be an area below the dividing line.

Figures 13A and 13B show further embodiments of the detector 110 according to the present invention comprising at least one bi-cell. The illumination source 136, such as a laser source, may generate the illumination light beam 138 illuminating object 112. The reflected light beam 116 may propagate from the object 112 to the transfer device 128 and may impinge on the bi-cell of optical sensors 118, 120. In Figure 13A a side view is shown and in Figure 13B a front view is shown. The detector 110 may comprise at least one FiP sensor adapted for generating the so called FiP effect as described in WO 2015/024871 or WO2016/120392. For example, the bi-cell in Figures 45 A and B may be adapted to generate a so called FiP signal. As outlined e.g. in WO 2015/024871 or WO2016/120392, the FiP signal can be used to determine depth information over a wide distance range. The FiP sensor may be adapted to exhibit a positive and/or a negative FiP effect. The negative FiP effect may be used to tune small image effects at high

distances. Image changes such as position, size, shape, sharpness, etc. may vanish at high distances while the negative FiP effect increases. Furthermore, no luminance dependence may be introduced since both cells are at the same longitudinal position and thus receive identical photon density.

Patent claims

1. A detector (110) for determining a position of at least one object (112), the detector (110) having
 - 5 - at least two optical sensors (118, 120, 176), each optical sensor (118, 120, 176) having a light-sensitive area (122, 124), wherein each light-sensitive area (122, 124) has a geometrical center (182, 184), wherein the geometrical centers (182, 184) of the optical sensors (118, 120, 176) are spaced apart from an optical axis (126) of the detector (110) by different spatial offsets, wherein each optical sensor (118, 120, 176) is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area (122, 124) by a light beam (116) propagating from the object (112) to the detector (110); and
 - at least one evaluation device (132) being configured for determining at least one longitudinal coordinate z of the object (112) by combining the at least two sensor signals.
- 15 2. The detector (110) according to the preceding claim, wherein the optical sensors (118, 120, 176) are part of a sensor array (174), wherein a geometrical center (180) of the sensor array (174) is offset from the optical axis (126).
- 20 3. The detector (110) according to the preceding claim, wherein the sensor array (174) is movable relative to the optical axis (126).
4. The detector (110) according to the preceding claim, wherein the evaluation device (132) is configured for, firstly, determining the transversal position of a light spot (186) generated by the light beam (116) on the sensor array (174) by using the sensor signals and for, secondly, moving the sensor array (174) relative to the optical axis (126) until the light spot (186) is off-centered.
- 25 5. The detector (110) according to any one of the preceding claims, wherein the optical sensors (118, 120, 176) are partial diodes of a quadrant diode (178), with a geometrical center (180) of the quadrant diode (178) being off-centered from the optical axis (126) of the detector (110).
- 30 6. The detector (110) according to any one of the preceding claims, wherein the evaluation device (132) is configured for deriving at least one quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals, and wherein the evaluation device (132) is further configured for determining the longitudinal coordinate by evaluating the quotient signal Q .
- 35 7. The detector (110) according to the preceding claim, wherein the evaluation device (132) is configured for using at least one predetermined relationship between the at least one quotient signal Q and the longitudinal coordinate.
- 40

- 5 8. The detector (110) according to any one of the preceding claims, wherein the detector (110) comprises at least one illumination source (136), wherein the illumination source (136) is adapted to illuminate the object (112) with at least one illumination light beam, wherein the illumination source (136) is arranged such that a direction of propagation of the illumination light beam is essentially parallel to the optical axis (126).
- 10 9. The detector (110) according to any one of the preceding claims, wherein the detector (110) comprises the at least one illumination source (136), wherein the illumination source (136) and the optical axis (126) are separated by a small baseline (202).
- 15 10. A detector system (134) for determining a position of at least one object (112), the detector system (134) comprising at least one detector (110) according to any one of the preceding claims, the detector system (134) further comprising at least one beacon device (114) adapted to direct at least one light beam (116) towards the detector (110), wherein the beacon device (114) is at least one of attachable to the object (112), holdable by the object (112) and integratable into the object (112).
- 20 11. A human-machine interface (148) for exchanging at least one item of information between a user (162) and a machine (170), wherein the human-machine interface (148) comprises at least one detector system (134) according to the preceding claim, wherein the at least one beacon device (114) is adapted to be at least one of directly or indirectly attached to the user (162) and held by the user (162), wherein the human-machine interface (148) is designed to determine at least one position of the user (162) by means of the detector system (134), wherein the human-machine interface (148) is designed to assign to the position at least one item of information.
- 25 12. An entertainment device (150) for carrying out at least one entertainment function, wherein the entertainment device (150) comprises at least one human-machine interface (148) according to the preceding claim, wherein the entertainment device (150) is designed to enable at least one item of information to be input by a player by means of the human-machine interface (148), wherein the entertainment device (150) is designed to vary the entertainment function in accordance with the information.
- 30 13. A tracking system (152) for tracking a position of at least one movable object (112), the tracking system (152) comprising at least one detector system (134) according to any one of the preceding claims referring to a detector system (134), the tracking system (152) further comprising at least one track controller (172), wherein the track controller (172) is adapted to track a series of positions of the object (112) at specific points in time.
- 35 14. A scanning system (154) for determining a depth profile of a scenery, the scanning system (154) comprising at least one detector (110) according to any of the preceding claims referring to a detector (110), the scanning system (154) further comprising at least one illumination source (136) adapted to scan the scenery with at least one light beam (116).
- 40

15. A camera (146) for imaging at least one object (112), the camera (146) comprising at least one detector (110) according to any one of the preceding claims referring to a detector (110).
16. A readout device (192) for optical storage media, the readout device (192) comprising at least one detector (110) according to any one of the preceding claims referring to a detector (110).
17. A method for determining a position of at least one object (112) by using at least one detector (110), the method comprising the following steps:
- providing at least two optical sensors (118, 120, 176), each optical sensor (118, 120, 176) having a light-sensitive area (122, 124), wherein each light-sensitive area (122, 124) has a geometrical center (182, 184), wherein the geometrical centers (182, 184) of the optical sensors (118, 120, 176) are spaced apart from an optical axis (126) of the detector (110) by different separations, wherein each optical sensor (118, 120, 176) is configured to generate a sensor signal in response to an illumination of its respective light-sensitive area (122, 124) by a light;
 - illuminating the at least two light-sensitive areas (122, 124) of the at least two optical sensors (118, 120, 176) of the detector (110) with a light beam (116) propagating from the object (112) to the detector (110) and, thereby, generating at least two sensor signals; and
 - evaluating the sensor signals by combining the at least two sensor signals, thereby determining at least one longitudinal coordinate z of the object (112).
18. The method according to the preceding claim, wherein the evaluating the sensor signals comprises deriving at least one quotient signal Q by one or more of dividing the sensor signals, dividing multiples of the sensor signals or dividing linear combinations of the sensor signals, and wherein the determining the longitudinal coordinate comprises evaluating the quotient signal Q .
19. A use of the detector (110) according to any one of the preceding claims relating to a detector (110), for a purpose of use, selected from the group consisting of: a position measurement in traffic technology; an entertainment application; an optical data storage application; a security application; a surveillance application; a safety application; a human-machine interface (148) application; a tracking application; a photography application; a logistics application; a machine vision application; a robotics application; a quality control application; a manufacturing application; a use for calibration of a distance measurement; a use in combination with optical data storage and readout.

(54) **Title:** DETECTOR FOR OPTICALLY DETECTING AT LEAST ONE OBJECT

FIG.1

(57) **Abstract:** A detector (110) for optically detecting at least one object (112) is proposed. The detector (110) comprises at least one optical sensor (114). The optical sensor (114) has at least one sensor region (116). The optical sensor (114) is designed to generate at least one sensor signal in a manner dependent on an illumination of the sensor region (116). The sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area (118). The detector (110) furthermore has at least one evaluation device (122). The evaluation device (122) is designed to generate at least one item of geometrical information from the sensor signal, in particular at least one item of geometrical information about the illumination and/or the object (112).

(84) **Designated States** (*unless otherwise indicated, for every kind of regional protection available*): ARIPO (BW, GH, GM, KE, LR, LS, MW, MZ, NA, RW, SD, SL, SZ, TZ, UG, ZM, ZW), Eurasian (AM, AZ, BY, KG, KZ, MD, RU, TJ, TM), European (AL, AT, BE, BG, CH, CY, CZ, DE, DK, EE, ES, FI, FR, GB, GR, HR, HU, IE, IS, IT, LT, LU, LV, MC, MK, MT, NL, NO, PL, PT, RO, RS,

Detector for optically detecting at least one object

Description

5 Field of the invention

The invention relates to a detector for optically detecting at least one object. Furthermore, the invention relates to a distance measuring device, an imaging device, a human-machine interface, an entertainment device and a security device. Furthermore,
10 the invention relates to a method for optically detecting at least one object and to a use of an organic solar cell as optical sensor. Such devices, methods and uses can be employed for example in various areas of daily life, traffic technology, production technology, security technology, medical technology or in the sciences. However, other applications are also possible in principle.

15

Prior art

A large number of optical sensors and photovoltaic devices are known from the prior art. While photovoltaic devices are generally used to convert electromagnetic radiation, for
20 example, ultraviolet, visible or infrared light, into electrical signals or electrical energy, optical detectors are generally used for picking up image information and/or for detecting at least one optical parameter, for example, a brightness.

A large number of optical sensors which can be based generally on the use of inorganic and/or organic sensor materials are known from the prior art. Examples of such sensors
25 are disclosed in US 2007/0176165 A1, US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1 or else in numerous other prior art documents. To an increasing extent, in particular for cost reasons and for reasons of large-area processing, sensors comprising at least one organic sensor material are being used, as described for
30 example in US 2007/0176165 A1. In particular, so-called dye solar cells are increasingly of importance here, which are described generally, for example in WO 2009/013282 A1.

A large number of detectors for detecting at least one object are known on the basis of such optical sensors. Such detectors can be embodied in diverse ways, depending on
35 the respective purpose of use. Examples of such detectors are imaging devices, for example, cameras and/or microscopes. High-resolution confocal microscopes are known, for example, which can be used in particular in the field of medical technology and biology in order to examine biological samples with high optical resolution. Further examples of detectors for optically detecting at least one object are distance measuring
40 devices based, for example, on propagation time methods of corresponding optical signals, for example laser pulses. Further examples of detectors for optically detecting

objects are triangulation systems, by means of which distance measurements can likewise be carried out.

Proceeding from such known detectors and methods for optically detecting objects, it can be ascertained that in many cases a considerable technical outlay has to be implemented in order to carry out this object detection with sufficient precision.

By way of example, in microscopy a considerable outlay in respect of apparatus is required in order to obtain correct focusing of a light beam and/or in order to obtain depth information about the sample to be imaged.

Distance measurements, by contrast, are based in many cases on technically inadequate assumptions such as, for example, the assumption of a specific size of an object in an image evaluation. Other methods are based in turn on complex pulse sequences, such as, for example, distance measurements by means of laser pulses. Yet other methods are based on the use of a plurality of detectors such as, for example, triangulation methods.

Problem addressed by the invention

Therefore, a problem addressed by the present invention is that of specifying devices and methods for optically detecting at least one object which at least substantially avoid the disadvantages of known devices and methods of this type. In particular, the proposed devices and methods are intended to make it possible to simplify an optical detection of at least one object in respect of apparatus.

Disclosure of the invention

This problem is solved by the invention with the features of the independent patent claims. Advantageous developments of the invention, which can be realized individually or in combination, are presented in the dependent claims.

A detector for optically detecting at least one object is proposed in a first aspect of the present invention.

In the context of the present invention, an optical detection should generally be understood to mean a process in which at least one item of information about the detected object is obtained. In this case, the term information should be interpreted broadly. The at least one item of information can comprise in particular one or more of the following items of information: an item of information about the fact that the object is present or not for example in a measurement range and/or visual range of the detector;

an item of information about at least one optical property of the detector, for example, at least one brightness and/or at least one radiation property, for example a luminescence property; an item of location information of the object, for example, an item of information about a distance between the object and the detector or a part of the detector and/or a relative orientation of the object with respect to the detector or a part of the detector and/or an item of position information of the object in at least one coordinate system which is determined by the detector and/or the object; an item of information about a movement state of the object, for example a one-dimensional, two-dimensional or three-dimensional velocity of the object and/or an acceleration of the object. Alternatively or additionally, other items of information can also be obtained during the detection of the object. The invention is described below substantially with reference to obtaining an item of location information about the object, without restriction of further embodiments of the at least one item of geometrical information which can be realized alternatively or additionally. Said geometrical information, in particular the location information, can relate to the entire object or else only a part of the object, for example a point, an area or a region of the object, which is detected by means of the detector. Said point, said area or said region can be arranged on a surface of the object or else at least partly within the object.

The object can generally be a living or else inanimate object. Examples of objects which can be detected completely or partly by means of the detector are described in even greater detail below.

The detector comprises at least one optical sensor. The optical sensor has at least one sensor region, in particular at least one sensor region comprising at least one sensor area. The optical sensor is designed to generate at least one sensor signal in a manner dependent on an illumination of the sensor region. The sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination in the sensor region, in particular on the sensor area.

The detector furthermore has at least one evaluation device. The evaluation device is designed to generate at least one item of geometrical information from the sensor signal, in particular at least one item of geometrical information about the illumination and/or the object.

The detector can furthermore comprise at least one transfer device. The transfer device can be designed to feed electromagnetic radiation emerging from the object to the optical sensor and to illuminate the sensor region in the process. In the context of the present invention, a transfer device should be understood to mean a device which is embodied in any desired manner, in principle, and which is designed to feed the electromagnetic

radiation emerging from the object to the optical sensor and there in particular to the sensor region or preferably the sensor area. This feeding can be embodied in imaging fashion or else in non-imaging fashion. Thus, this optional transfer device can comprise for example at least one beam path. The transfer device can for example comprise one or a plurality of mirrors and/or beam splitters and/or beam deflecting elements in order to influence a direction of the electromagnetic radiation. Alternatively or additionally, the transfer device can comprise one or a plurality of imaging elements which can have the effect of a converging lens and/or a diverging lens. By way of example, the optional transfer device can have one or a plurality of lenses and/or one or a plurality of convex and/or concave mirrors. Once again alternatively or additionally, the transfer device can have at least one wavelength-selective element, for example at least one optical filter. Once again alternatively or additionally, the transfer device can be designed to impress a predefined beam profile on the electromagnetic radiation, for example, at the location of the sensor region and in particular the sensor area. The abovementioned optional embodiments of the optional transfer device can, in principle, be realized individually or in any desired combination.

In the context of the present invention, an optical sensor should be understood generally to mean an element which is designed to convert at least one optical signal into a different signal form, preferably into at least one electrical signal, for example a voltage signal and/or a current signal. In particular the optical sensor can comprise at least one optical-electrical converter element, preferably at least one photodiode and/or at least one solar cell. As is explained in even greater detail below, in the context of the present invention, preference is attached particularly to a use of at least one organic optical sensor, that is to say an optical sensor which comprises at least one organic material, for example at least one organic semiconductor material.

In the context of the present invention, a sensor region should be understood to mean a two-dimensional or three-dimensional region which preferably, but not necessarily, is continuous and can form a continuous region, wherein the sensor region is designed to vary at least one measurable property, in a manner dependent on the illumination. By way of example, said at least one property can comprise an electrical property, for example, by the sensor region being designed to generate, solely or in interaction with other elements of the optical sensor, a photovoltage and/or a photocurrent and/or some other type of signal. In particular the sensor region can be embodied in such a way that it generates a uniform, preferably a single, signal in a manner dependent on the illumination of the sensor region. The sensor region can thus be the smallest unit of the optical sensor for which a uniform signal, for example, an electrical signal, is generated, which preferably can no longer be subdivided to partial signals, for example for partial regions of the sensor region. The optical sensor can have one or else a plurality of such

sensor regions, the latter case for example by a plurality of such sensor regions being arranged in a two-dimensional and/or three-dimensional matrix arrangement.

5 The at least one sensor region can comprise for example at least one sensor area, that is to say a sensor region whose lateral extent considerably exceeds the thickness of the sensor region, for example by at least a factor of 10, preferably by at least a factor of 100 and particularly preferably by at least a factor of 1000. Examples of such sensor areas can be found in organic or inorganic photovoltaic elements, for example, in accordance with the prior art described above, or else in accordance with the exemplary
10 embodiments described in even greater detail below. The detector can have one or a plurality of such optical sensors and/or sensor regions. By way of example, a plurality of optical sensors can be arranged linearly in a spaced-apart manner or in a two-dimensional arrangement or else in a three-dimensional arrangement, for example by a stack of photovoltaic elements being used, preferably organic photovoltaic elements,
15 preferably a stack in which the sensor areas of the photovoltaic elements are arranged parallel to one another. Other embodiments are also possible.

The optional transfer device can, as explained above, be designed to feed
20 electromagnetic radiation emerging from the object to the optical sensor. As explained above, this feeding can optionally be effected by means of imaging or else by means of non-imaging properties of the transfer device. In particular the transfer device can also be designed to collect the electromagnetic radiation before the latter is fed to the optical sensor. The optional transfer device can also, as explained in even greater detail below, be wholly or partly a constituent part of at least one optional illumination source, for
25 example by the illumination source being designed to provide electromagnetic radiation having defined optical properties, for example having a defined or precisely known beam profile, for example at least one Gaussian beam, in particular at least one laser beam having a known beam profile.

30 The electromagnetic radiation can be in particular light in one or more of the following spectral ranges: in the ultraviolet spectral range, in the visible spectral range, in the infrared spectral range. The ultraviolet spectral range can be considered to be for example a range with a wavelength of 50 nm to 400 nm, the visible spectral range a range of 400 nm to 800 nm, and the infrared spectral range a range of 800 nm to
35 100 000 nm.

The electromagnetic radiation emerging from the object can originate in the object itself, but can also optionally have a different origin and propagate from this origin to the object and subsequently toward the optical sensor and the sensor region. The latter case can
40 be effected for example by at least one illumination source being used. This illumination source can be for example ambient light or else an artificial illumination source. By way

of example, the detector itself can comprise at least one illumination source, for example at least one laser and/or at least one incandescent lamp and/or at least one semiconductor light source, for example, at least one light-emitting diode, in particular an organic and/or inorganic light-emitting diode. On account of their generally defined beam profiles and other properties of handleability, the use of one or a plurality of lasers as illumination source or as part thereof, is particularly preferred. The illumination source itself can be a constituent part of the detector or else be formed independently of the detector. The illumination source can be integrated in particular into the detector, for example a housing of the detector. Alternatively or additionally, at least one illumination source can also be integrated into the object or connected or spatially coupled to the object.

The electromagnetic radiation emerging from the object can accordingly, alternatively or additionally from the option that said radiation originates in the object itself emerge from the illumination source and/or be excited by the illumination source. By way of example, the electromagnetic radiation emerging from the object can be emitted by the object itself and/or be reflected by the object and/or be scattered by the object before it is fed to the optical sensor. In this case, emission and/or scattering of the electromagnetic radiation can be effected without spectral influencing of the electromagnetic radiation or with such influencing. Thus, by way of example, a wavelength shift can also occur during scattering, for example according to Stokes or Raman. Furthermore, emission of radiation can be excited, for example, by a primary light source, for example by the object or a partial region of the object being excited to effect luminescence, in particular phosphorescence and/or fluorescence. Other emission processes are also possible, in principle. If a reflection occurs, then the object can have for example at least one reflective region, in particular at least one reflective surface. Said reflective surface can be a part of the object itself, but can also be for example a reflector which is connected or spatially coupled to the object, for example a reflector plaque connected to the object. If at least one reflector is used, then it can in turn also be regarded as part of the detector which is connected to the object, for example, independently of other constituent parts of the detector. The at least one illumination source of the detector can generally be adapted to the emission and/or reflective properties of the object, for example in terms of its wavelength. Various embodiments are possible.

The feeding of the electromagnetic radiation to the optical sensor can be effected in particular in such a way that a light spot, for example having a round, oval or differently configured cross section, is produced on the optional sensor area. By way of example, the detector can have a visual range, in particular a solid angle range and/or spatial range, within which objects can be detected. Preferably, the optional transfer device is designed in such a way that the light spot, for example in the case of an object arranged within a visual range of the detector, is arranged completely on the sensor region, in

particular the sensor area. By way of example, a sensor area can be chosen to have a corresponding size in order to ensure this condition.

As described above, the optical sensor is designed to generate at least one sensor
5 signal in a manner dependent on the illumination of the sensor region. By way of
example, this can be an electrical signal, in particular a voltage signal and/or current
signal, for example a photovoltage and/or a photocurrent. Hereinafter, without restricting
possible further embodiments, reference is made in particular to optical sensors which, in
10 a manner dependent on the illumination generate at least one photocurrent. The optical
signal can be temporally constant or vary temporally and can be embodied, in principle,
in analog fashion or else in digital fashion, wherein analog signals are preferred
hereinafter. The sensor signal can be used as a raw signal, but can also be subjected to
one or a plurality of processing operations, for example one or a plurality of filtering
15 operations or similar processing operations. No distinction is drawn hereinafter between
these options and the use of a raw signal, and the term sensor signal is used uniformly.
Furthermore, without restricting further possible embodiments, it is assumed that the
sensor signal has positive values, and the term of a maximum should for example, also
be understood in this respect. If one or a plurality of sensor signals having a negative
20 sign are detected, which is likewise possible, then hereinafter either the expression of the
maximum should be replaced by the term of a minimum or generally of an extremum, or
the actual sensor signal should be replaced, for example by its absolute value, as will
readily be evident to the person skilled in the art.

As explained above, the optical sensor is designed to generate at least one sensor signal
25 in a manner dependent on the illumination of the sensor region, wherein the sensor
signal, given the same total power of the illumination, is dependent on a geometry of the
illumination, in particular on a beam cross section of the illumination on the sensor area.

A geometry of the illumination can generally summarize at least one property of the
30 illumination which characterizes a two-dimensional and/or three-dimensional
embodiment of a region of the sensor region which is exposed to the electromagnetic
radiation emerging from the object. By way of example, the geometry of the illumination
can be characterized by a beam cross section of the illumination on or in the sensor
35 region, for example on a sensor surface, for example by a diameter or equivalent
diameter of the illumination, for example of a light spot. As described above, a light spot
which can have for example a diameter or an equivalent diameter can be produced for
example on the sensor area. Said diameter or equivalent diameter can completely or
partly characterize for example the geometry of the illumination. A light spot can be
40 understood to mean for example an illuminated area, in particular in demarcation relative
to an unilluminated area. By way of example, light spot can be understood to mean an

area of the sensor region within which an intensity of the illumination is at least 10% of a maximum intensity. However, other definitions of a light spot are also possible, in principle, for example by other limit values being set instead of 10%, since an edge of the illumination in practice, will not be sharply defined by virtue of the intensity falling abruptly
5 to zero.

The optical sensor can be designed for example in such a way that the sensor signal, given the same power of the illumination, that is to say for example given the same integral over the intensity of the illumination on the sensor area, is dependent on the
10 geometry of the illumination, that is to say for example on the diameter and/or the equivalent diameter for the sensor spot. By way of example, the sensor can be designed in such a way that upon a doubling of the beam cross section given the same total power, a signal variation occurs by at least a factor of 3, preferably by at least a factor of 4, in particular a factor of 5 or even a factor of 10. This condition can hold true for
15 example for a specific focusing range, for example for at least one specific beam cross section. Thus, by way of example, the signal can have, between at least one optimum focusing at which the signal can have for example at least one global or local maximum and a focusing outside said at least one optimum focusing, a signal difference by at least a factor of 3, preferably by at least a factor of 4, in particular a factor of 5 or even a factor
20 of 10. In particular, the sensor signal can have as a function of the geometry of the illumination, for example of the diameter or equivalent diameter of a light spot, at least one pronounced maximum, for example with a boost by at least a factor of 3, particularly preferably by at least a factor of 4 and particularly preferably by at least a factor of 10.

Consequently, the invention is based generally on the hitherto unreported and surprising insight that specific optical sensors exist whose sensor signal is not only dependent on a total light power of the illumination of the sensor region, for example of the sensor area, of these sensors but in which a pronounced signal dependence on a geometry of the illumination, for example a size of a light spot of the illumination on the sensor region, for
30 example the sensor area, also exists. This is generally not the case for most conventional optical sensors, in particular for most inorganic semiconductor sensors, since here the sensor signal is generally dependent only on a total power of the illumination, that is to say an integral over the intensity over the entire light spot which is generally independent of the size of the light spot, that is to say the geometry of the
35 illumination, as long as the light spot lies within the limits of the sensor region. It has surprisingly been discovered, however, that in specific optical sensors, for example organic optical sensors, such a dependence of the sensor signal occurs in which the sensor signal on the one hand rises with the total power of the illumination, but on the other hand, even given a constant total power, is dependent on a geometry of the
40 illumination. Examples of such optical sensors are explained in even greater detail below. By way of example, the sensor signal, given the same total power, can have at

least one pronounced maximum for one or a plurality of focusings and/or for one or a plurality of specific sizes of the light spot on the sensor area or within the sensor region. This effect can additionally be dependent on, or intensified by, a frequency of the illumination by virtue of the fact that the electromagnetic radiation with which the sensor region is illuminated is not incident continuously on the sensor region, but rather is interrupted, for example interrupted periodically with a frequency f . The described optical sensors which have the stated effect of the dependence of the sensor signal, given the same total power of the illumination on a geometry of the illumination and optionally on a frequency of the illumination, are also designated hereinafter as fip sensors since, given the same total power p , the sensor signal can be dependent on the intensity i and optionally the frequency f or since the sensor signal, given the same total power p , can be dependent on an optical flux density Φ . By way of example, the sensor signal can comprise a photocurrent and/or a photovoltage. By way of example, the photocurrent can thus be a function of the total power p , of the flux Φ and/or of the geometry of the illumination (e.g. of a diameter or an equivalent diameter of a light spot) and optionally of the frequency, or for example a function of the total power p , of the intensity (for example of a maximum intensity) and of the frequency.

Such effects of the dependence of the sensor signal on a beam geometry were observed in the context of the investigations leading to the present invention in particular in the case of organic photovoltaic components, that is to say photovoltaic components, for example, solar cells, which comprise at least one organic material, for example at least one organic p-semiconducting material and/or at least one organic dye. By way of example, such effects, as is explained in even greater detail below by way of example, were observed in the case of dye solar cells, that is to say components which have at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid organic p-type semiconductor, and at least one second electrode. Such dye solar cells, preferably solid dye solar cells (solid dye sensitized solar cells, sDSC), are known in principle in numerous variations from the literature. The described effect of the dependence of the sensor signal on a geometry of the illumination on the sensor area and a use of this effect have not, however, been described heretofore.

In particular, the optical sensor can be designed in such a way that the sensor signal, given the same total power of the illumination, is substantially independent of a size of the sensor region, in particular of a size of the sensor area, in particular as long as the light spot of the illumination lies completely within the sensor region, in particular the sensor area. Consequently, the sensor signal can be dependent exclusively on a focusing of the electromagnetic rays on the sensor area. In particular the sensor signal can be embodied in such a way that a photocurrent and/or a photovoltage per sensor

area have/has the same values given the same illumination, for example the same values given the same size of the light spot.

Consequently, by means of the optical detector, for example by a suitable calibration and/or by a suitable analysis of the sensor signal of the optical sensor, at least one additional item of information can be obtained, which is designated hereinafter as geometrical information. The detector comprises at least one evaluation device which is designed to generate the at least one item of geometrical information from the sensor signal.

An item of geometrical information should be understood to mean, in principle, any desired item of information which can be derived directly or indirectly from the abovementioned effect that the sensor signal, given the same total power of the illumination, is dependent on the geometry of the illumination. The geometrical information can comprise, in particular, at least one item of information about the illumination, in particular a geometry of the illumination, and/or at least one item of geometrical information about the object. The geometrical information can, in particular, go beyond an item of information about the light power alone. The geometrical information can preferably comprise at least one item of information about the geometry of the illumination and/or at least one item of information about at least one influencing variable which influences the geometry of the illumination for example an item of information about a distance of the object.

Particularly preferably the geometrical information comprises at least one item of information, selected from the group consisting of: an item of information about the fact that the object is present or not for example in a measurement range and/or visual range of the detector; an item of information about at least one optical property of the detector, for example, at least one brightness and/or at least one radiation property, for example a luminescence property; an item of location information of the object, for example, an item of information about a distance between the object and the detector or a part of the detector and/or a relative orientation of the object with respect to the detector or a part of the detector and/or an item of position information of the object in at least one coordinate system which is determined by the detector and/or the object; an item of information about a movement state of the object, for example a one-dimensional, two-dimensional or three-dimensional velocity of the object and/or an acceleration of the object; an item of information about a geometry of the illumination of the sensor region; an item of information about the fact that an illumination has taken place or is taking place with a specific geometry, in particular an inhomogeneous illumination of the sensor region, in particular a focused illumination, for example an illumination in which at least one light spot is produced on a sensor area. Alternatively or additionally, the geometrical information can also comprise one or a plurality of other items of information. The

invention is described below substantially with reference to obtaining an item of geometrical information in the form of at least one item of location information about the object. Said location information can relate to the entire object or else only a part of the object, for example a point, an area or a region of the object which is detected by means
5 of the detector. This point, this area or this region can be arranged on a surface of the object or else at least partly within the object.

The geometrical information can be generated in any desired form, in principle. Preferably, the geometrical information is generated in a machine-readable form and/or a
10 form that can be used by a machine. By way of example, the geometrical information can be generated in the form of at least one electrical and/or optical signal. Alternatively or additionally, the geometrical information can also be generated in a form that can be read and/or detected by a human, for example by printout on paper, by display on a screen, by an output in visual form, by an output in acoustic form, by an output in haptic
15 form or by a combination of two or more of the stated and/or other output forms that can be detected by a human. The geometrical information may have been stored or can be stored in particular on at least one volatile or nonvolatile data memory which can be for example wholly or partly a constituent part of the evaluation device and/or of some other device. Alternatively or additionally, the at least one item of geometrical information can
20 also be provided and/or transferred by means of at least one interface, for example by means of at least one output device.

An evaluation device should generally be understood to mean a device which is designed to generate the at least one item of geometrical information from the at least
25 one sensor signal, using the above-described effect that the sensor signal, given the same total power of the illumination, is dependent on the geometry of the illumination. In particular, in this case it is possible to use a known relationship between the geometry of the illumination and the geometrical function, as is explained in even greater detail below by way of example.

The evaluation device can comprise in particular at least one data processing device, in particular an electronic data processing device, which can be designed to use the at least one sensor signal as at least one input variable and to generate the at least
35 geometrical information using said input variable, for example by calculation and/or using at least one stored and/or known relationship. Besides the at least one sensor signal, one or a plurality of further parameters and/or items of information can influence said relationship, for example at least one item of information about a modulation frequency. In this case, the relationship can be determined or determinable empirically, analytically or else semi-empirically. Particularly preferably, the relationship comprises at least one
40 calibration curve, at least one set of calibration curves, at least one function or a combination of the possibilities mentioned. One or a plurality of calibration curves can be

stored for example in the form of a set of values and the associated function values thereof, for example in a data storage device and/or a table. Alternatively or additionally, however, the at least one calibration curve can also be stored for example in parameterized form and/or as a functional equation. Various possibilities are conceivable and can also be combined.

By way of example, the evaluation device can be designed in terms of programming for the purpose of determining the at least one item of geometrical information. The evaluation device can comprise in particular at least one computer, for example at least one microcomputer. Furthermore, the evaluation device can comprise one or a plurality of volatile or nonvolatile data memories. As an alternative or in addition to a data processing device, in particular at least one computer, the evaluation device can comprise one or a plurality of further electronic components which are designed for determining the at least one item of geometrical information using the at least one sensor signal, for example an electronic table and in particular at least one look-up table and/or at least one application-specific integrated circuit (ASIC).

The geometrical information allows a multiplicity of possible uses of such detectors, which will be described by way of example hereinafter. By way of example, as is explained in even greater detail below, at least one item of location information of the object can be generated from said geometrical information, or the geometrical information can comprise the at least one item of location information, since for example a geometry of the illumination, for example a diameter or equivalent diameter of the light spot on the sensor area, can be dependent on a distance between the object and the detector and/or the optional transfer device of the detector, for example at least one detector lens. By way of example, a variation of the distance between the object and a lens of the optional transfer device can lead to a defocusing of the illumination on the sensor region, accompanied by a change in the geometry of the illumination, for example a widening of a light spot, which can result in a correspondingly altered sensor signal. Even without a transfer device, by way of example, from a known beam profile from the sensor signal and/or a variation thereof, for example, by means of a known beam profile and/or a known propagation of the electromagnetic rays, it is possible to deduce a defocusing and/or the geometrical information. By way of example, given a known total power of the illumination, it is thus possible to deduce from the sensor signal of the optical sensor a geometry of the illumination and therefrom in turn the geometrical information, in particular at least one item of location information of the object.

Preferably, at least two sensor signals are detected. If the total power of the illumination is not known, for example, then for example at least two sensor signals can be generated, for example at least two sensor signals at different frequencies of a modulation of the illumination, wherein, from the at least two sensor signals, for example

by comparison with corresponding calibration curves, it is possible to deduce the total power and/or the geometry of the illumination, and/or therefrom or directly the at least one item of geometrical information, in particular the at least one item of location information, of the object. In any case, the detector can thus be designed to generate, in particular on the basis of the effect described, the at least one item of geometrical information, which preferably goes beyond pure information about the total power of the illumination.

The detector described can advantageously be developed in various ways. Thus, the detector can furthermore have at least one modulation device for modulating the illumination, in particular for periodic modulation, in particular a periodic beam interrupting device. A modulation of the illumination should be understood to mean a process in which a total power of the illumination is varied, preferably periodically, in particular with one or a plurality of modulation frequencies. In particular, a periodic modulation can be effected between a maximum value and a minimum value of the total power of the illumination. The minimum value can be 0, but can also be > 0 , such that, by way of example, complete modulation does not have to be effected. The modulation can be effected for example in a beam path between the object and the optical sensor, for example by the at least one modulation device being arranged in said beam path. Alternatively or additionally, however, the modulation can also be effected in a beam path between an optional illumination source - described in even greater detail below - for illuminating the object and the object, for example by the at least one modulation device being arranged in said beam path. A combination of these possibilities is also conceivable. The at least one modulation device can comprise for example a beam chopper or some other type of periodic beam interrupting device, for example comprising at least one interrupter blade or interrupter wheel, which preferably rotates at constant speed and which can thus periodically interrupt the illumination. Alternatively or additionally, however, it is also possible to use one or a plurality of different types of modulation devices, for example modulation devices based on an electro-optical effect and/or an acousto-optical effect. Once again alternatively or additionally, the at least one optional illumination source itself can also be designed to generate a modulated illumination, for example by said illumination source itself having a modulated intensity and/or total power, for example a periodically modulated total power, and/or by said illumination source being embodied as a pulsed illumination source, for example as a pulsed laser. Thus, by way of example, the at least one modulation device can also be wholly or partly integrated into the illumination source. Various possibilities are conceivable.

The detector can be designed in particular to detect at least two sensor signals in the case of different modulations, in particular at least two sensor signals at respectively different modulation frequencies. The evaluation device can be designed to generate the

geometrical information from the at least two sensor signals. As described above, in this way, by way of example, it is possible to resolve ambiguities and/or it is possible to take account of the fact that, for example, a total power of the illumination is generally unknown.

5

Further possible embodiments of the detector relate to the embodiment of the at least one optional transfer device. As explained above, said at least one transfer device can have imaging properties or else can be embodied as a pure non-imaging transfer device, which has no influence on a focusing of the illumination. It is particularly preferred, however, if the transfer device has at least one imaging element, for example at least one lens and/or at least one curved mirror, since, in the case of such imaging elements, for example, a geometry of the illumination on the sensor region can be dependent on a relative positioning, for example a distance, between the transfer device and the object. Generally, it is particularly preferred if the transfer device is designed in such a way that the electromagnetic radiation which emerges from the object is transferred completely to the sensor region, for example is focused completely onto the sensor region, in particular the sensor area, in particular if the object is arranged in a visual range of the detector.

As explained above, the optical sensor can furthermore be designed in such a way that the sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination. The detector can be embodied, in particular, as explained above, in such a way that sensor signals at different modulation frequencies are picked up, for example in order to generate one or a plurality of further items of information about the object. As described above, by way of example, a sensor signal at at least two different modulation frequencies can in each case be picked up, wherein, by way of example, in this way, a lack of information about a total power of the illumination can be supplemented. By way of example, by comparing the at least two sensor signals picked up at different modulation frequencies with one or a plurality of calibration curves, which can be stored for example in a data storage device of the detector, even in the case of an unknown total power of the illumination, it is possible to deduce a geometry of the illumination, for example a diameter or an equivalent diameter of a light spot on the sensor area. For this purpose, by way of example, it is possible to use the at least one evaluation device described above, for example at least one data processing data, which can be designed to control such picking-up of sensor signals at different frequencies and which can be designed to compare said sensor signals with the at least one calibration curve in order to generate therefrom the geometrical information, for example information about a geometry of the illumination, for example information about a diameter or equivalent diameter of a light spot of the illumination on a sensor area of the optical sensor. Furthermore, as is explained in even greater detail below, the evaluation device can alternatively or additionally be designed to generate at least one item of geometrical information about

the object, for example at least one item of location information. This generation of the at least one item of geometrical information, as explained above, can be effected for example taking account of at least one known relationship between a positioning of the object relative to the detector and/or the transfer device or a part thereof and a size of a light spot, for example empirically, semi-empirically or analytically using corresponding imaging equations.

In contrast to known detectors, in which a spatial resolution and/or imaging of objects is also generally tied to the fact that the smallest possible sensor areas are used, for example the smallest possible pixels in the case of CCD chips, the sensor region of the proposed detector can be embodied in a very large fashion, in principle, since for example the geometrical information, in particular the at least one item of location information, about the object can be generated from a known relationship for example between the geometry of the illumination and the sensor signal. Accordingly, the sensor region can have for example a sensor area, for example an optical sensor area, which is at least 0.001 mm^2 , in particular at least 0.01 mm^2 , preferably at least 0.1 mm^2 , more preferably at least 1 mm^2 , more preferably at least 5 mm^2 , more preferably at least 10 mm^2 , in particular at least 100 mm^2 or at least 1000 mm^2 or even at least $10\,000 \text{ mm}^2$. In particular, sensor areas of 100 cm^2 or more can be used. The sensor area can generally be adapted to the application. In particular, the sensor area should be chosen in such a way that, at least if the object is situated within a visual range of the detector, preferably within a predefined viewing angle and/or a predefined distance from the detector, the light spot is always arranged within the sensor area. In this way, it can be ensured that the light spot is not trimmed by the limits of the sensor region, as a result of which signal corruption could occur.

As described above, the sensor region can be in particular a continuous sensor region, in particular a continuous sensor area, which can preferably generate a uniform, in particular a single, sensor signal. Consequently, the sensor signal can be in particular a uniform sensor signal for the entire sensor region, that is to say a sensor signal to which each partial region of the sensor region contributes, for example additively. The sensor signal can generally, as explained above, in particular be selected from the group consisting of a photocurrent and a photovoltage.

The optical sensor can comprise in particular at least one semiconductor detector and/or be at least one semiconductor detector. In particular, the optical sensor can comprise at least one organic semiconductor detector or be at least one organic semiconductor detector, that is to say a semiconductor detector comprising at least one organic semiconducting material and/or at least one organic sensor material, for example at least one organic dye. Preferably, the organic semiconductor detector can comprise at least one organic solar cell and particularly preferably a dye solar cell, in particular a solid dye

solar cell. Exemplary embodiments of such preferred solid dye solar cells are explained in even greater detail below.

In particular, the optical sensor can comprise at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably at least one solid p-semiconducting organic material, and at least one second electrode. Generally, however, it is pointed out that the described effect in which the sensor signal, given a constant total power, is dependent on a geometry of the illumination of the sensor region is with high probability not restricted to organic solar cells and in particular not to dye solar cells. Without intending to restrict the scope of protection of the invention by this theory, and without the invention being bound to the correctness of this theory, it is supposed that generally photovoltaic elements are suitable as optical sensors in which at least one semiconducting material having trap states is used. Consequently, the optical sensor can comprise at least one n-semiconducting material and/or at least one p-semiconducting material which can have for example a conduction band and a valence band, wherein, in the case of organic materials, conduction band and valence band should correspondingly be replaced by LUMO (lowest unoccupied molecular orbital) and HOMO (highest occupied molecular orbital). Trap states should be understood to mean energetically possible states which are disposed between the conduction band (or LUMO) and the valence band (or HOMO) and which can be occupied by charge carriers. By way of example, it is possible to provide trap states for hole conduction which are disposed at at least one distance ΔE_h above the valence band (or HOMO) and/or trap states for electron conduction which are disposed at at least one distance ΔE_e below the conduction band (or LUMO). Such traps can be achieved for example by impurities and/or defects, which can optionally also be introduced in a targeted manner, or can be present intrinsically. By way of example, in the case of a low intensity, that is to say for example in the case of a light spot having a large diameter, only a low current can flow, since firstly the trap states are occupied before holes in the conduction band or electrons in the valence band contribute to a photocurrent. It is only starting from a higher intensity, that is to say for example starting from a more intense focusing of the light spot in the sensor region, that a considerable photocurrent can then flow. The described frequency dependence can be explained for example by the fact that charge carriers leave the traps again after a residence duration τ , such that the described effect occurs only in the case of modulated illumination with a high modulation frequency. By way of example, the detector can be designed to bring about a modulation of the illumination of the sensor region with a frequency of at least 1 Hz, preferably at least 10 Hz, in particular at least 100 Hz and particularly preferably at least 1 kHz. The trap states can be present for example with a density of 10^{-5} to 10^{-1} , relative to the n-semiconducting material and/or the p-semiconducting material and/or the dye. The energy differences ΔE with respect to the conduction band and with respect to the valence band can be in particular 0.05-0.3 eV.

The detector has, as described above, at least one evaluation device. In particular, the at least one evaluation device can also be designed to completely or partly control or drive the detector, for example by the evaluation device being designed to control one or a plurality of modulation devices of the detector and/or to control at least one illumination source of the detector. The evaluation device can be designed, in particular, to carry out at least one measurement cycle in which one or a plurality of sensor signals are picked up, for example a plurality of sensor signals successively at different modulation frequencies of the illumination.

The evaluation device is designed, as described above, to generate the at least one item of geometrical information from the at least one sensor signal. The at least one item of geometrical information can, in particular, as explained above, comprise at least one item of location information of the object and/or can be at least one item of location information of the object. In this case, an item of location information should generally be understood to mean an item of information which is adapted and/or suited to characterize at least one location and/or at least one orientation of the object or of a part of the object, for example of a region of the object, from which the electromagnetic radiation emerges. Said at least one item of location information can be static, that is to say can comprise for example a single item of location information or a plurality of items of location information which are picked up at the same time, but can, alternatively or additionally, also comprise a plurality of items of location information which are picked up at different times. By way of example, in this way, the at least one item of location information can also comprise at least one item of information about at least one movement, for example a relative movement between the detector or parts thereof and the object or parts thereof. In this case, a relative movement can generally comprise at least one linear movement and/or at least one rotational movement. Items of movement information can for example also be obtained by comparison of at least two items of location information picked up at different times, such that for example at least one item of location information can also comprise at least one item of velocity information and/or at least one item of acceleration information, for example at least one item of information about at least one relative velocity between the object or parts thereof and the detector or parts thereof. In particular, the at least one item of location information can generally be selected from: an item of information about a distance between the object or parts thereof and the detector or parts thereof, in particular an optical path length; an item of information about a distance or an optical distance between the object or parts thereof and the optional transfer device or parts thereof; an item of information about a positioning of the object or parts thereof relative to the detector or parts thereof; an item of information about an orientation of the object and/or parts thereof relative to the detector or parts thereof; an item of information about a relative movement between the object or parts thereof and the detector or parts thereof; an item of information about a two-dimensional or three-

dimensional spatial configuration of the object or of parts thereof, in particular a geometry or form of the object. Generally, the at least one item of location information can therefore be selected for example from the group consisting of: an item of information about at least one location of the object or at least one part thereof; information about at least one orientation of the object or a part thereof; an item of information about a geometry or form of the object or of a part thereof, an item of information about a velocity of the object or of a part thereof, an item of information about an acceleration of the object or of a part thereof, an item of information about a presence or absence of the object or of a part thereof in a visual range of the detector.

The at least one item of location information can be specified for example in at least one coordinate system, for example a coordinate system in which the detector or parts thereof rest. Alternatively or additionally, the location information can also simply comprise for example a distance between the detector or parts thereof and the object or parts thereof. Combinations of the possibilities mentioned are also conceivable.

The evaluation device can, as explained above, in particular be designed to determine the geometrical information from at least one predefined relationship between the geometry of the illumination, for example a diameter or equivalent diameter of a luminous spot on the sensor region and/or the sensor area, and a relative positioning of the object with respect to the detector, for example a distance and/or an optical path length between object and detector, preferably taking account of a known power of the illumination and optionally taking account of a modulation frequency with which the illumination is modulated. By way of example, the evaluation device can comprise at least one data storage device in which is stored a predefined relationship between a distance between detector and object and a geometry of the illumination, for example a diameter or equivalent diameter of a luminous spot on the sensor region. Said relationship can be stored for example in discrete fashion or continuously or else in the form of a function. By way of example, said relationship can comprise at least one calibration function. The relationship can for example also be stored in an electronic table, for example a so-called look-up table. If a power of the illumination is not known, then, as explained above, for example the evaluation device can be designed to pick up sensor signals at at least two different modulation frequencies of the illumination. Generally, the evaluation device can be designed for example to deduce in one or a plurality of steps, firstly, for example, from the at least one sensor signal, the geometry of the illumination, for example a diameter or equivalent diameter of a luminous spot on the sensor region or the sensor area. Furthermore, the evaluation device can be designed to deduce the at least one item of geometrical information from this determined geometry, preferably taking account of the modulation frequency. These two deductions can also be combined in one step, such that, by way of example, the evaluation device can be designed to directly deduce the geometrical information, in particular the location

information, from the at least one sensor signal. Examples of such relationships by means of which the evaluation device can generate the at least one item of geometrical information are explained in even greater detail below, including possible calibration curves. In particular in the case of a relationship between the geometry of the illumination and the geometrical information, in this case it is also possible to use analytical or semi-empirical models, for example imaging equations. Thus, by way of example, the illumination can be effected by means of one or a plurality of Gaussian beams, wherein for example the at least one item of geometrical information can be generated by the beam geometry and the Gaussian beam parameters of the illumination, for example by means of corresponding optical matrix calculations. By way of example, imaging parameters of the optional transfer device can be known, for example one or a plurality of focal lengths of one or a plurality of lenses and/or curved mirrors of the transfer device, such that, by way of example, a relationship between a positioning of the object relative to the transfer device and a geometry of the illumination of the sensor region, for example a diameter or equivalent diameter of the luminous spot, can be calculated. By way of example, Gaussian matrix optics and/or some other form of an imaging equation can be used for this purpose.

As explained above, the detector can furthermore comprise at least one illumination source for generating electromagnetic rays. The illumination source can be designed in particular to bring about the illumination of the sensor region. Thus, the illumination source can be designed for example to generate a primary radiation with which the object or a part of the object is irradiated, whereupon the electromagnetic radiation emerges from the object and is transferred to the optical sensor and the sensor region thereof, for example by means of the at least one optional transfer device. As explained above, the electromagnetic radiation by means of which the sensor region is illuminated can comprise for example the primary radiation in reflected or scattered form. Alternatively or additionally, however, for example an influencing of the primary radiation can also be effected, for example a spectral shift and/or a process in which the primary radiation emitted by the illumination source excites the object or a part thereof to emit the electromagnetic radiation, for example by excitation of luminescence.

The illumination source can be embodied in various ways. Thus, the illumination source can be for example part of the detector in a detector housing. Alternatively or additionally, however, the at least one illumination source can also be arranged outside a detector housing, for example as a separate light source. The illumination source can be arranged separately from the object and illuminate the object from a distance. Alternatively or additionally, the illumination source can also be connected to the object or even be part of the object, such that, by way of example, the electromagnetic radiation emerging from the object can also be generated directly by the illumination source. By way of example, at least one illumination source can be arranged on and/or in the object

and directly generate the electromagnetic radiation by means of which the sensor region is illuminated. By way of example, at least one infrared emitter and/or at least one emitter for visible light and/or at least one emitter for ultraviolet light can be arranged on the object. By way of example, at least one light emitting diode and/or at least one laser diode can be arranged on and/or in the object. The illumination source can comprise in particular one or a plurality of the following illumination sources: a laser, in particular a laser diode, although in principle, alternatively or additionally, other types of lasers can also be used; a light emitting diode; an incandescent lamp; an organic light source, in particular an organic light emitting diode. Alternatively or additionally, other illumination sources can also be used. It is particularly preferred if the illumination source is designed to generate electromagnetic beams having a Gaussian beam profile, as is at least approximately the case for example in many lasers. However, other embodiments are also possible, in principle.

Furthermore, it should be noted that the optional transfer device described above can be embodied independently of the optional at least one illumination source. Alternatively or additionally, however, the at least one transfer device can also already be wholly or partly integrated into the illumination source or be wholly or partly identical to said illumination source. Thus, the illumination source itself can already be designed to feed the electromagnetic radiation to the sensor region, for example by a corresponding orientation toward the sensor region and/or by a focusing and/or a corresponding beam profile. By way of example, the illumination source can comprise at least one laser which can already generate at least one laser beam having a known beam profile, for example a Gaussian beam profile, such that, by way of example, it is possible to dispense with beam shaping by one or a plurality of lens systems, since, by way of example, from corresponding equations a propagation of Gaussian beams, from a known beam geometry upon identification of a geometry of the illumination on the sensor region, for example a diameter or equivalent diameter of a luminous spot on the sensor region, a distance between the illumination source and the detector and/or the object and the detector can be deduced. Alternatively or additionally, however, the transfer device can comprise one or a plurality of additional imaging elements, for example one or a plurality of lenses and/or objectives. Alternatively or additionally, by way of example, one or a plurality of deflection elements can be included, for example one or a plurality of mirrors and/or one or a plurality of prisms.

Generally, therefore, as already mentioned above, the illumination source can in particular be selected in particular from an illumination source which is at least partly connected to the object and/or is at least partly identical to the object, and an illumination source which is designed to at least partly illuminate the object. Various other embodiments are possible and are described in even greater detail below by way of example.

The detector can therefore comprise at least one illumination source. The illumination source can be designed in particular to illuminate the object with at least one primary radiation. Said at least one primary radiation can comprise electromagnetic radiation, for example light, but can, alternatively or additionally, also comprise at least one radiation of a different type, for example a particle radiation. The electromagnetic radiation which emerges from the object and which is fed to the optical sensor and illuminates the sensor region in the process can, as already described in part above, comprise in particular a reflected radiation, wherein the reflected radiation can comprise at least part of the primary radiation after reflection at the object. Alternatively or additionally, the electromagnetic radiation emerging from the object can also comprise at least one scattered radiation, wherein the scattered radiation comprises at least one part of the primary radiation after scattering at the object. As explained above, this scattering can be effected without spectral properties being influenced or else with spectral properties being influenced. Once again alternatively or additionally, the electromagnetic radiation emerging from the object can also comprise at least one luminescent radiation which is excited by the primary radiation. Said luminescent radiation can comprise for example a fluorescent radiation and/or a phosphorus radiation. Other possibilities for the embodiment of the electromagnetic radiation which emerges from the object, or combinations of the stated and/or other possibilities, are also conceivable.

A further aspect of the present invention proposes a distance measuring device, in particular for use in a motor vehicle. In this case, a distance measuring device should be understood to mean a device which is designed to generate at least one item of location information of at least one object, for example relative to the distance measuring device itself. As explained above, said at least one item of location information can comprise for example a simple distance between the distance measuring device and the object, but can also generally comprise at least one item of information about a positioning of the object relative to the distance measuring device, for example a spatial positioning in at least one coordinate system and/or an orientation of the object in at least one coordinate system. For further embodiments of the at least one item of location information, reference can be made to the above description.

The proposed distance measuring device accordingly comprises at least one detector in accordance with one or a plurality of the embodiments described above, wherein the detector is designed to determine at least one item of geometrical information of at least one object, wherein the geometrical information comprises at least one item of location information of the object, in particular a distance between a motor vehicle and at least one object and preferably a distance between the motor vehicle and at least one object selected from the group consisting of a further motor vehicle, an obstacle, a cyclist and a pedestrian. In particular, the detector can be completely or partly integrated in one or a

plurality of motor vehicles and can be designed to determine a distance between a motor vehicle and at least one object, for example a distance between two motor vehicles and/or a distance between the motor vehicle and at least one object selected from the group consisting of a further motor vehicle, an obstacle, a cyclist, a pedestrian or some other kind of traffic participant. The detector can be for example completely integrated into the motor vehicle, but can also be arranged for example in a manner distributed over a plurality of motor vehicles. By way of example, as is explained in even greater detail below by way of example, the distance measuring device can comprise at least one detector and at least one illumination source, wherein, by way of example, the at least one illumination source is arranged on a rear side of a first motor vehicle, and the detector is arranged on a front side of at least one second motor vehicle, such that, by way of example, a distance between a front side of the second motor vehicle and a rear side of the first motor vehicle can be determined. Alternatively or additionally, at least one illumination source and at least one detector can also be integrated into one and the same motor vehicle, for example on a front side and/or a rear side of the motor vehicle. Thus, by way of example, the illumination source can be designed to illuminate a motor vehicle ahead and/or a following motor vehicle with primary radiation, and the detector can be designed to detect the electromagnetic radiation emerging from said motor vehicle, as described above, and to generate the location information therefrom.

A further aspect of the present invention proposes an imaging device for imaging at least one sample. In this case, an imaging device should generally be understood to mean a device which can generate a one-dimensional, a two-dimensional or a three-dimensional image of the sample or of a part of said sample.

In particular, the imaging device can be completely or partly used as a microscope. Preferably, the image device is designed for confocal imaging, that is to say has a confocal construction, or is designed as a confocal microscope. Other embodiments of the imaging device are also possible in principle, however, and are described in even greater detail below by way of example.

The imaging device has at least one detector in accordance with one or more of the embodiments described above. The imaging device is furthermore designed to image a plurality of partial regions of the sample successively or simultaneously onto the at least one sensor region of the detector. In this case, by way of example, a partial region of the sample can be a one-dimensional, two-dimensional or three-dimensional region of the sample which is delimited for example by a resolution limit of the imaging device and from which electromagnetic radiation emerges, which, on the sensor region of the detector, leads to an illumination, for example a common luminous spot, in particular on a sensor area. The plurality of partial regions can be imaged successively and/or simultaneously onto the at least one sensor region. In this context, imaging should be

understood to mean that electromagnetic radiation of the sample emerging from the respective partial region is fed to the optical sensor, for example by means of the at least one optional transfer device of the detector.

- 5 With regard to the possible embodiments of the optional transfer device, reference can be made to the above description. In particular, the transfer device can have imaging properties and can comprise for example at least one imaging element, for example at least one lens and/or at least one curved mirror. In particular, the imaging device can be designed to image sequentially, for example by means of a scanning method, in
10 particular using at least one row scan and/or line scan, the plurality of partial regions sequentially onto the sensor region. However, other embodiments are also possible, in principle, for example embodiments in which a plurality of partial regions are simultaneously imaged onto the at least one sensor region, for example by at least one sensor region being assigned to each partial region. By way of example, it is possible to
15 use a detector having a plurality of sensor regions, for example in accordance with one or more of the embodiments described above.

The imaging device is designed to generate, during this imaging of the partial regions of the sample, sensor signals assigned to the partial regions. By way of example, a sensor
20 signal can be assigned to each partial region. The sensor signals can accordingly be generated simultaneously or else in a temporally staggered manner. By way of example, during a row scan or line scan, it is possible to generate a sequence of sensor signals which correspond to the partial regions of the sample, which are strung together in a line, for example. The imaging device is designed to generate from the sensor signals items
25 of geometrical information of the respective partial regions, wherein the items of geometrical information comprise items of location information.

With regard to the embodiment of the items of location information and the various possibilities for generating these items of location information, reference can be made to
30 the above description. The electromagnetic rays emerging from the sample can once again be generated by the sample itself, for example in the form of a luminescent radiation. Alternatively or additionally, the imaging device or the at least one detector can also once again comprise at least one illumination source for illuminating the sample. For further possible embodiments of the imaging device, in particular for use in microscopy,
35 reference can be made to the exemplary embodiments below.

A further aspect of the present invention proposes a human-machine interface for exchanging at least one item of information between a user and a machine. A human-machine interface should generally be understood to mean a device by means of which
40 such information can be exchanged. The machine can comprise in particular a data processing device. The at least one item of information can generally comprise for

example data and/or control commands. Thus, the human-machine interface can be designed in particular for the inputting of control commands by the user.

The human-machine interface has at least one detector in accordance with one or a plurality of the embodiments described above. The human-machine interface is designed to generate at least one item of geometrical information, in particular at least one item of location information, of the user by means of the detector. By way of example, said at least one item of geometrical information can be or comprise an item of location information about a body part of the user, for example an item of location information about a hand posture and/or a posture of some other body part of the user.

In this case, the term user should be interpreted broadly and can for example also encompass one or a plurality of articles directly influenced by the user. Thus, the user can for example also wear one or a plurality of gloves and/or other garments, wherein the geometrical information is at least one item of geometrical information of this at least one garment. By way of example, such garments can be embodied as reflective to a primary radiation emerging from at least one illumination source, for example by the use of one or a plurality of reflectors. Once again alternatively or additionally, the user can for example spatially move one or a plurality of articles whose geometrical information can be detected, which is likewise also intended to be subsumable under generation of at least one item of geometrical information of the user. By way of example, the user can move at least one reflective rod and/or some other type of article, for example by means of said user's hand.

With regard to the embodiment of the at least one item of geometrical information, in particular the at least one item of location information, reference can likewise once again be made to the above description. The at least one item of geometrical information can be static, that is to say can for example once again comprise a snapshot, but can also for example once again comprise a series of sequential items of geometrical information and/or at least one movement. By way of example, at least two items of geometrical information picked up at different times can be compared, such that, by way of example, the at least one item of geometrical information can also comprise at least one item of information about a velocity and/or an acceleration of a movement. Accordingly, the at least one item of geometrical information can for example comprise at least one item of information about at least one body posture and/or about at least one movement of the user.

The human-machine interface is designed to assign to the at least one item of geometrical information at least one item of information, in particular at least one control command. As explained above, the term information should in this case be interpreted broadly and can comprise for example data and/or control commands. By way of

example, the human-machine interface can be designed to assign the at least one item of information to the at least one item of geometrical information, for example by means of a corresponding assignment algorithm and/or a stored assignment specification. By way of example, a unique assignment between a set of items of geometrical information and corresponding items of information can be stored. In this way, for example by means of a corresponding body posture and/or movement of the user, an inputting of at least one item of information can be effected.

Such human-machine interfaces can generally be used in the machine control or else for example in virtual reality. By way of example, robot controllers, vehicle controllers or similar controllers can be made possible by means of the human-machine interface having the one or the plurality of detectors. However, the use of such a human-machine interface in consumer electronics is particularly preferred. Accordingly, a further aspect of the present invention proposes an entertainment device for carrying out at least one entertainment function, in particular a game. The entertainment function can comprise in particular at least one game function. By way of example, one or a plurality of games can be stored which can be influencable by a user, who in this context is also called a player hereinafter. By way of example, the entertainment device can comprise at least one display device, for example at least one screen and/or at least one projector and/or at least one set of display spectacles.

The entertainment device furthermore comprises at least one human-machine interface in accordance with one or more of the embodiments described above. The entertainment device is designed to enable at least one item of information of a player to be input by means of the human-machine interface. By way of example, the player, as described above, can adopt or alter one or a plurality of body postures for this purpose. This includes the possibility of the player for example using corresponding articles for this purpose, for example garments such as e.g. gloves, for example garments which are equipped with one or a plurality of reflectors for reflecting the electromagnetic radiation of the detector. The at least one item of information can comprise for example, as explained above, one or a plurality of control commands. By way of example, in this way, changes in direction can be performed, inputs can be confirmed, a selection can be made from a menu, specific game options can be initiated, movements can be influenced in a virtual space or similar instances of influencing or altering the entertainment function can be performed.

A further aspect of the present invention proposes using the detector in a security device. As described above, by means of the detector, in particular the at least one evaluation device, it is possible to generate at least one item of geometrical information which preferably goes beyond a pure item of information about the total power of the illumination. Said at least one item of geometrical information can, inter alia, also be or

comprise an item of information about the fact that an illumination has taken place or is taking place with a specific geometry, in particular an inhomogeneous illumination of the sensor region, in particular a focused illumination, for example an illumination in which at least one light spot is produced on a sensor area. The proposed security device is therefore based for example on the insight that, by means of the proposed detector, it is possible to identify if intensive electromagnetic radiation, for example a focused light beam and in particular a laser beam, impinges on an article comprising the detector. By way of example, in this way it can be identified that a read-out of optically readable data of an optical data storage device has been effected, for example of a CD-ROM, of a bar code or of some other type of data storage device.

Accordingly, a security device for carrying out at least one security application is proposed. A security device should generally be understood to mean a device which fulfils at least one security function, for example a function which recognizes an access to data and can optionally implement one or a plurality of corresponding measures according to the situation. A security function can generally be a function which recognizes an access to an article or data and optionally prevents it or at least makes it more difficult. The at least one security application can accordingly comprise in particular at least one application in the field of data protection. In particular, the at least one security application can be an application in which an access, in particular an unauthorized access, to data of an optical data storage device is recognized and/or avoided. The optical data storage device can comprise, in principle, any desired type of optical data storage device, for example one or a plurality of the optical data storage devices mentioned above.

The security device furthermore comprises at least one detector in accordance with one or more of the above-described claims relating to a detector. In this respect, it should be pointed out that, in accordance with the above description, the detector can optionally comprise the at least one transfer device. In the security device, such a transfer device is not absolutely necessary, since, by way of example, as described above, the electromagnetic radiation can also be focused by a laser and/or an external imaging device, for example at least one external lens.

Accordingly, the security device or the detector of said security device can also be embodied without such a transfer device, or the illumination source or parts thereof can be regarded as a transfer device or parts thereof. On the other hand, the transfer device can also be wholly or partly integrated into an illumination source, such that the security device can also be embodied in a multipartite fashion. By way of example, the transfer device, as described above, can be wholly or partly integrated into an illumination source, which can likewise be regarded as a constituent part of the security device, but

which need not be formed integrally with the other parts of the security device, for example with the optical sensor of the detector of the security device.

The security device is furthermore designed to recognize, by means of the detector, 5 impingement of focused electromagnetic rays onto the security device, in particular impingement of one or a plurality of laser beams, in particular focused laser beams. By way of example, the security device can comprise the at least one evaluation device for this purpose, as described above. By way of example, this recognition can be effected by virtue of the fact that the at least one sensor signal of the at least one detector is 10 compared with at least one threshold value. While non-focused light can generate for example a sensor signal below said threshold value, for example focused light having the same total power which impinges on the sensor region can generate a sensor signal which reaches or exceeds the at least one threshold value. By way of example, a photocurrent or an absolute value of the photocurrent can be compared with said at least 15 one threshold value. In this way, it is possible for example to recognize if at least one reading beam, for example a weak laser beam, is radiated in so as to read out optically readable data. Even if said reading beam is chosen, in terms of its total power, to be so weak that overall there impinges on the sensor region a total power which does not exceed for example the total power of ambient light, for example assuming an ambient 20 light intensity of 1 to $1 \cdot 10^5$ W/m², such a reading beam can be recognized by means of the at least one detector according to the invention. Focused electromagnetic rays can be understood to mean electromagnetic rays by means of which only a partial region of the sensor region of the detector is irradiated with a boosted intensity, for example only a light spot of less than 10 mm², in particular of less than 1 mm² and particularly preferably 25 of less than 0.1 mm², although the focusing can be dependent on the application. For the definition of a light spot which can be for example a round, oval or else differently shaped light spot, reference can be made to the above description.

The security device can furthermore be designed, if impingement of such focused 30 electromagnetic rays is recognized, to perform at least one security function or further security functions. By way of example, the security device, in particular the evaluation device, can be designed to generate at least one warning signal. Said at least one warning signal can comprise for example at least one signal, in particular selected from the group consisting of an acoustic signal, an electrical signal, an optical signal and a 35 haptic signal. Alternatively or additionally, the warning signal can also comprise at least one variation of at least one state of at least one data storage device of the security device. By way of example, it is possible to use at least one data storage device with at least one read-out bit, wherein the at least one read-out bit can be changed over from a state "not read out" to a state "read out" by means of the at least one warning signal. 40 Alternatively or additionally, however, the warning signal can also be designed for example to bring about, after recognition of impingement of focused electromagnetic

rays, destruction of the security device and/or of the data storage device, such that only a single use is possible. The warning signal can for example also be output to a user and/or some other device.

5 The security device mentioned can be designed or applied in various ways. By way of example, the security device can be embodied as a security label, for example as a security label having at least one optical data storage device and the at least one detector. By way of example, in this way it is possible to prevent multiple uses of access
10 authorizations, for example tickets for events, for example by virtue of a first read-out being identified and/or by virtue of especially a focus light beam being radiated onto the detector. Alternatively or additionally, however, the security device can also be integrated for example into an optical data storage device, such that it is possible to embody an optical data storage device with a security device of this type. The at least one security
15 device can for example be embodied in such a way that the at least one sensor region of the at least one detector is arranged in direct spatial proximity to at least one optically readable data storage device, for example at least one data field of at least one optical ROM, and/or in direct proximity to a bar code and/or a holographic data storage device and/or as a constituent part thereof. In this way, it can be ensured, for example, that a
20 reading beam by means of which data are read out optically from the data storage device inevitably also impinges on the sensor region of the detector. By way of example, a spatial distance between the sensor region and the data storage device region can be not more than 5 mm, in particular not more than 1 mm and particularly preferably not more than 0.1 mm.

25 A further aspect of the present invention proposes a method for optically detecting at least one object. The method can be effected in particular using a detector in accordance with one or more of the embodiments described above, such that, with regard to optional embodiments of the method, reference can be made to the above description of the detector. In the method, at least one optical sensor is used, wherein the optical sensor
30 has at least one sensor region. Electromagnetic radiation emerging from the object is fed to the sensor, wherein the sensor region is illuminated. The optical sensor generates at least one sensor signal in a manner dependent on the illumination of the sensor region, wherein the sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination.

35 For further possible embodiments of the method, reference can be made to the above description. In particular, from the sensor signal it is possible to generate at least one item of geometrical information of the object, preferably at least one item of location information of the object, which preferably goes beyond a pure item of information about
40 the total power of the illumination. For possible embodiments of this geometrical information, reference can be made to the above description. In particular, this

geometrical information can comprise at least one item of location information of the object. With regard to possible embodiments of this location information, reference can likewise be made to the above description. The geometrical information can be determined in particular using at least one predefined relationship between the geometry of the illumination and a location of the object, preferably taking account of a known power of the illumination and/or taking account of a modulation frequency with which the illumination is modulated. In particular, therefore, the method can be embodied in such a way that the illumination is modulated, in particular is modulated periodically, with a modulation frequency which can be constant or else variable.

A further aspect of the present invention proposes a use of a detector in accordance with one or more of the embodiments described above for a purpose of use, which is selected from the group consisting of: distance measurement, in particular in traffic technology; imaging, in particular in microscopy; an entertainment application; a human-machine interface application; a security application. However, other uses of the detector are also possible, in principle.

A further aspect of the present invention proposes the use of an organic solar cell, in particular a dye solar cell and preferable a solid dye solar cell, as optical sensor, for example in a detector in accordance with one or more of the embodiments described above. In the use, at least one sensor signal is generated, wherein the sensor signal, given the same total power of an illumination of at least one sensor region of the optical sensor, is dependent on a geometry of the illumination on the organic solar cell, in particular a sensor area of the organic solar cell, wherein at least one item of geometrical information of at least one object is generated from the sensor signal in the use. For further possible embodiments of this use, reference can be made to the above description.

The above-described detector, the method, the distance measuring device, the imaging device, the human-machine interface, the entertainment device and the security device and also the proposed uses have considerable advantages over the prior art. Thus, in particular the outlay for object detection can be distinctly reduced by means of the proposed detector and by means of the proposed method. For distance measurements for example or other types of object detection, by way of example, technically complex propagation time measurements in which pulse propagation times of laser pulses are detected, for example, can be at least substantially avoided. In contrast to conventional imaging methods, it is possible in a simple manner, for example with erroneous assumptions being avoided, to generate items of geometrical information, in particular items of location information, about a detected object, without for example detectors having a high spatial resolution, for example a high number of pixels, being absolutely necessary for this purpose. By way of example, it is possible to use a detector having a

comparatively large sensor area, for example in accordance with the embodiment described above, on which a light spot is produced by electromagnetic radiation emerging from the object. The sensor signal can be, in particular, independent of the position of said light spot on the sensor region, for example the sensor area, as long as said light spot is arranged completely within the sensor region. However, the detector can be designed to deduce from the focusing of the electromagnetic rays, for example from a diameter or equivalent diameter of the light spot on the sensor area, the at least one item of geometrical information, for example the distance between the object and the detector. Such an application can be realized technically in an extremely simple manner. Furthermore, it is possible to use cost-effective optical sensors, in particular large-area optical sensors, which can be producible for example using one or a plurality of organic materials. In particular, it is possible to use solar cells, for example organic solar cells and in particular dye solar cells, which are produced as mass-produced products in photovoltaics. In this way, for the detector proposed, a multiplicity of new fields of application open up which were withheld from previous detectors in many cases on account of their high costs, such as, for example, applications in disposable articles or data storage devices.

As explained above, the optical sensor can comprise in particular an organic semiconductor detector, particularly preferably a dye solar cell. In particular, the optical sensor can comprise at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material and at least one second electrode, preferably in the stated order. The stated elements can be present as layers in a layer construction, for example. The layer construction can be applied for example to a substrate, preferably a transparent substrate, for example a glass substrate.

Preferred embodiments of the abovementioned elements of the preferred optical sensor are described below by way of example, wherein these embodiments can be used in any desired combination. However, numerous other configurations are also possible, in principle, wherein reference can be made for example to US 2007/0176165 A1, US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1 and WO 2009/013282 A1 cited above.

First electrode and n-semiconductive metal oxide

The n-semiconductive metal oxide used in the dye solar cell may be a single metal oxide or a mixture of different oxides. It is also possible to use mixed oxides. The n-semiconductive metal oxide may especially be porous and/or be used in the form of a nanoparticulate oxide, nanoparticles in this context being understood to mean particles which have an average particle size of less than 0.1 micrometer. A nanoparticulate oxide

is typically applied to a conductive substrate (i.e. a carrier with a conductive layer as the first electrode) by a sintering process as a thin porous film with large surface area.

5 The substrate may be rigid or else flexible. Suitable substrates (also referred to hereinafter as carriers) are, as well as metal foils, in particular plastic sheets or films and especially glass sheets or glass films. Particularly suitable electrode materials, especially for the first electrode according to the above-described, preferred structure, are conductive materials, for example transparent conductive oxides (TCOs), for example
10 fluorine- and/or indium-doped tin oxide (FTO or ITO) and/or aluminum-doped zinc oxide (AZO), carbon nanotubes or metal films. Alternatively or additionally, it would, however, also be possible to use thin metal films which still have a sufficient transparency. The substrate can be covered or coated with these conductive materials. Since generally only a single substrate is required in the structure proposed, the formation of flexible cells is also possible. This enables a multitude of end uses which would be achievable only with
15 difficulty, if at all, with rigid substrates, for example use in bank cards, garments, etc.

The first electrode, especially the TCO layer, may additionally be covered or coated with a solid metal oxide buffer layer (for example of thickness 10 to 200 nm), in order to prevent direct contact of the p-type semiconductor with the TCO layer (see Peng *et al.*,
20 Coord. Chem. Rev. 248, 1479 (2004)). The inventive use of solid p-semiconducting electrolytes, in the case of which contact of the electrolyte with the first electrode is greatly reduced compared to liquid or gel-form electrolytes, however, makes this buffer layer unnecessary in many cases, such that it is possible in many cases to dispense with this layer, which also has a current-limiting effect and can also worsen the contact of the
25 n-semiconducting metal oxide with the first electrode. This enhances the efficiency of the components. On the other hand, such a buffer layer can in turn be utilized in a controlled manner in order to match the current component of the dye solar cell to the current component of the organic solar cell. In addition, in the case of cells in which the buffer layer has been dispensed with, especially in solid cells, problems frequently occur with
30 unwanted recombinations of charge carriers. In this respect, buffer layers are advantageous in many cases specifically in solid cells.

As is well known, thin layers or films of metal oxides are generally inexpensive solid semiconductor materials (n-type semiconductors), but the absorption thereof, due to
35 large bandgaps, is typically not within the visible region of the electromagnetic spectrum, but rather usually in the ultraviolet spectral region. For use in solar cells, the metal oxides therefore generally, as is the case in the dye solar cells, have to be combined with a dye as a photosensitizer, which absorbs in the wavelength range of sunlight, i.e. at 300 to 2000 nm, and, in the electronically excited state, injects electrons into the conduction
40 band of the semiconductor. With the aid of a solid p-type semiconductor used

additionally in the cell as an electrolyte, which is in turn reduced at the counterelectrode, electrons can be recycled to the sensitizer, such that it is regenerated.

Of particular interest for use in organic solar cells are the semiconductors zinc oxide, tin dioxide, titanium dioxide or mixtures of these metal oxides. The metal oxides can be used in the form of nanocrystalline porous layers. These layers have a large surface area which is coated with the dye as a sensitizer, such that a high absorption of sunlight is achieved. Metal oxide layers which are structured, for example nanorods, give advantages such as higher electron mobilities or improved pore filling by the dye.

The metal oxide semiconductors can be used alone or in the form of mixtures. It is also possible to coat a metal oxide with one or more other metal oxides. In addition, the metal oxides may also be applied as a coating to another semiconductor, for example GaP, ZnP or ZnS.

Particularly preferred semiconductors are zinc oxide and titanium dioxide in the anatase polymorph, which is preferably used in nanocrystalline form.

In addition, the sensitizers can advantageously be combined with all n-type semiconductors which typically find use in these solar cells. Preferred examples include metal oxides used in ceramics, such as titanium dioxide, zinc oxide, tin(IV) oxide, tungsten(VI) oxide, tantalum(V) oxide, niobium(V) oxide, cesium oxide, strontium titanate, zinc stannate, complex oxides of the perovskite type, for example barium titanate, and binary and ternary iron oxides, which may also be present in nanocrystalline or amorphous form.

Due to the strong absorption that customary organic dyes and phthalocyanines and porphyrins have, even thin layers or films of the n-semiconducting metal oxide are sufficient to absorb the required amount of dye. Thin metal oxide films in turn have the advantage that the probability of unwanted recombination processes falls and that the internal resistance of the dye subcell is reduced. For the n-semiconducting metal oxide, it is possible with preference to use layer thicknesses of 100 nm up to 20 micrometers, more preferably in the range between 500 nm and approx. 3 micrometers.

Dye

In the context of the present invention, as usual in particular for DSCs, the terms "dye", "sensitizer dye" and "sensitizer" are used essentially synonymously without any restriction of possible configurations. Numerous dyes which are usable in the context of the present invention are known from the prior art, and so, for possible material examples, reference may also be made to the above description of the prior art regarding

dye solar cells. All dyes listed and claimed may in principle also be present as pigments. Dye-sensitized solar cells based on titanium dioxide as a semiconductor material are described, for example, in US-A-4 927 721, Nature 353, p. 737-740 (1991) and US-A-5 350 644, and also Nature 395, p. 583-585 (1998) and EP-A-1 176 646. The dyes
5 described in these documents can in principle also be used advantageously in the context of the present invention. These dye solar cells preferably comprise monomolecular films of transition metal complexes, especially ruthenium complexes, which are bonded to the titanium dioxide layer via acid groups as sensitizers.

10 Not least for reasons of cost, sensitizers which have been proposed repeatedly include metal-free organic dyes, which are likewise also usable in the context of the present invention. High efficiencies of more than 4%, especially in solid dye solar cells, can be achieved, for example, with indoline dyes (see, for example, Schmidt-Mende *et al.*, Adv. Mater. 2005, 17, 813). US-A-6 359 211 describes the use, also implementable in the
15 context of the present invention, of cyanine, oxazine, thiazine and acridine dyes which have carboxyl groups bonded via an alkylene radical for fixing to the titanium dioxide semiconductor.

Organic dyes now achieve efficiencies of almost 12.1% in liquid cells (see, for example,
20 P. Wang *et al.*, ACS. Nano 2010). Pyridinium-containing dyes have also been reported, can be used in the context of the present invention and exhibit promising efficiencies.

Particularly preferred sensitizer dyes in the dye solar cell proposed are the perylene derivatives, terrylene derivatives and quaterrylene derivatives described in
25 DE 10 2005 053 995 A1 or WO 2007/054470 A1. The use of these dyes, which is also possible in the context of the present invention, leads to photovoltaic elements with high efficiencies and simultaneously high stabilities.

The rylenes exhibit strong absorption in the wavelength range of sunlight and can,
30 depending on the length of the conjugated system, cover a range from about 400 nm (perylene derivatives I from DE 10 2005 053 995 A1) up to about 900 nm (quaterrylene derivatives I from DE 10 2005 053 995 A1). Rylene derivatives I based on terrylene absorb, according to the composition thereof, in the solid state adsorbed onto titanium dioxide, within a range from about 400 to 800 nm. In order to achieve very substantial
35 utilization of the incident sunlight from the visible into the near infrared region, it is advantageous to use mixtures of different rylene derivatives I. Occasionally, it may also be advisable also to use different rylene homologs.

The rylene derivatives I can be fixed easily and in a permanent manner to the n-semiconducting metal oxide film. The bonding is effected via the anhydride function (x1)
40 or the carboxyl groups –COOH or –COO– formed in situ, or via the acid groups A present

in the imide or condensate radicals ((x2) or (x3)). The rylene derivatives I described in DE 10 2005 053 995 A1 have good suitability for use in dye-sensitized solar cells in the context of the present invention.

5 It is particularly preferred when the dyes, at one end of the molecule, have an anchor group which enables the fixing thereof to the n-type semiconductor film. At the other end of the molecule, the dyes preferably comprise electron donors Y which facilitate the regeneration of the dye after the electron release to the n-type semiconductor, and also prevent recombination with electrons already released to the semiconductor.

10 For further details regarding the possible selection of a suitable dye, it is possible, for example, again to refer to DE 10 2005 053 995 A1. By way of example, it is possible especially to use ruthenium complexes, porphyrins, other organic sensitizers, and preferably rylenes.

15 The dyes can be fixed onto or into the n-semiconducting metal oxide films in a simple manner. For example, the n-semiconducting metal oxide films can be contacted in the freshly sintered (still warm) state over a sufficient period (for example about 0.5 to 24 h) with a solution or suspension of the dye in a suitable organic solvent. This can be
20 accomplished, for example, by immersing the metal oxide-coated substrate into the solution of the dye.

If combinations of different dyes are to be used, they may, for example, be applied successively from one or more solutions or suspensions which comprise one or more of
25 the dyes. It is also possible to use two dyes which are separated by a layer of, for example, CuSCN (on this subject see, for example, Tennakone, K.J., Phys. Chem. B. 2003, 107, 13758). The most convenient method can be determined comparatively easily in the individual case.

30 In the selection of the dye and of the size of the oxide particles of the n-semiconducting metal oxide, the organic solar cell should be configured such that a maximum amount of light is absorbed. The oxide layers should be structured such that the solid p-type semiconductor can efficiently fill the pores. For instance, smaller particles have greater surface areas and are therefore capable of adsorbing a greater amount of dyes. On the
35 other hand, larger particles generally have larger pores which enable better penetration through the p-conductor.

p-semiconducting organic material

40 As described above, the optical sensor can comprise in particular at least one p-semiconducting organic material, preferably at least one solid p-semiconducting material,

which is also designated hereinafter as p-type semiconductor or p-type conductor. Hereinafter a description is given of a series of preferred examples of such organic p-type semiconductors which can be used individually or else in any desired combination, for example in a combination of a plurality of layers with a respective p-type semiconductor, and/or in a combination of a plurality of p-type semiconductors in one layer.

In order to prevent recombination of the electrons in the n-semiconducting metal oxide with the solid p-conductor, it is possible to use, between the n-semiconducting metal oxide and the p-type semiconductor, at least one passivating layer which has a passivating material. This layer should be very thin and should as far as possible cover only the as yet uncovered sites of the n-semiconducting metal oxide. The passivation material may, under some circumstances, also be applied to the metal oxide before the dye. Preferred passivation materials are especially one or more of the following substances: Al_2O_3 ; silanes, for example CH_3SiCl_3 ; Al^{3+} ; 4-tert-butylpyridine (TBP); MgO ; GBA (4-guanidinobutyric acid) and similar derivatives; alkyl acids; hexadecylmalonic acid (HDMA).

As described above, in the context of the organic solar cell, preferably one or more solid organic p-type semiconductors are used – alone or else in combination with one or more further p-type semiconductors which are organic or inorganic in nature. In the context of the present invention, a p-type semiconductor is generally understood to mean a material, especially an organic material, which is capable of conducting holes, that is to say positive charge carriers. More particularly, it may be an organic material with an extensive π -electron system which can be oxidized stably at least once, for example to form what is called a free-radical cation. For example, the p-type semiconductor may comprise at least one organic matrix material which has the properties mentioned. Furthermore, the p-type semiconductor can optionally comprise one or a plurality of dopants which intensify the p-semiconducting properties. A significant parameter influencing the selection of the p-type semiconductor is the hole mobility, since this partly determines the hole diffusion length (cf. Kumara, G., *Langmuir*, 2002, 18, 10493-10495). A comparison of charge carrier mobilities in different spiro compounds can be found, for example, in T. Saragi, *Adv. Funct. Mater.* 2006, 16, 966-974.

Preferably, in the context of the present invention, organic semiconductors are used (i.e. low molecular weight, oligomeric or polymeric semiconductors or mixtures of such semiconductors). Particular preference is given to p-type semiconductors which can be processed from a liquid phase. Examples here are p-type semiconductors based on polymers such as polythiophene and polyarylamines, or on amorphous, reversibly oxidizable, nonpolymeric organic compounds, such as the spirobifluorenes mentioned at the outset (cf., for example, US 2006/0049397 and the spiro compounds disclosed

therein as p-type semiconductors, which are also usable in the context of the present invention). Preference is given to using low molecular weight organic semiconductors. In addition, reference may also be made to the remarks regarding the p-semiconducting materials and dopants from the above description of the prior art.

5

The p-type semiconductor is preferably producible or produced by applying at least one p-conducting organic material to at least one carrier element, wherein the application is effected for example by deposition from a liquid phase comprising the at least one p-conducting organic material. The deposition can in this case once again be effected, in principle, by any desired deposition process, for example by spin-coating, knife-coating, printing or combinations of the stated and/or other deposition methods.

10

The organic p-type semiconductor may especially comprise at least one spiro compound and/or especially be selected from: a spiro compound, especially spiro-MeOTAD; a compound with the structural formula:

15

in which

20

A^1 , A^2 , A^3 are each independently optionally substituted aryl groups or heteroaryl groups,

R^1 , R^2 , R^3 are each independently selected from the group consisting of the substituents $-R$, $-OR$, $-NR_2$, $-A^4-OR$ and $-A^4-NR_2$,

25

where R is selected from the group consisting of alkyl, aryl and heteroaryl,

and

where A^4 is an aryl group or heteroaryl group, and

where n at each instance in formula I is independently a value of 0, 1, 2 or 3,

with the proviso that the sum of the individual n values is at least 2 and at least two of the R^1 , R^2 and R^3 radicals are -OR and/or -NR₂.

Preferably, A^2 and A^3 are the same; accordingly, the compound of the formula (I) preferably has the following structure (Ia)

More particularly, as explained above, the p-type semiconductor may thus have at least one low molecular weight organic p-type semiconductor. A low molecular weight material is generally understood to mean a material which is present in monomeric, nonpolymerized or nonoligomerized form. The term "low molecular weight" as used in the present context preferably means that the p-type semiconductor has molecular weights in the range from 100 to 25 000 g/mol. Preferably, the low molecular weight substances have molecular weights of 500 to 2000 g/mol.

In general, in the context of the present invention, p-semiconducting properties are understood to mean the property of materials, especially of organic molecules, to form holes and to transport these holes and/or to pass them on to adjacent molecules. More particularly, stable oxidation of these molecules should be possible. In addition, the low molecular weight organic p-type semiconductors mentioned may especially have an extensive π -electron system. More particularly, the at least one low molecular weight p-type semiconductor may be processable from a solution. The low molecular weight p-type semiconductor may especially comprise at least one triphenylamine. It is particularly preferred when the low molecular weight organic p-type semiconductor comprises at least one spiro compound. A spiro compound is understood to mean polycyclic organic compounds whose rings are joined only at one atom, which is also referred to as the spiro atom. More particularly, the spiro atom may be sp^3 -hybridized, such that the constituents of the spiro compound connected to one another via the spiro atom are, for example, arranged in different planes with respect to one another.

More preferably, the spiro compound has a structure of the following formula:

where the aryl¹, aryl², aryl³, aryl⁴, aryl⁵, aryl⁶, aryl⁷ and aryl⁸ radicals are each independently selected from substituted aryl radicals and heteroaryl radicals, especially from substituted phenyl radicals, where the aryl radicals and heteroaryl radicals, preferably the phenyl radicals, are each independently substituted, preferably in each case by one or more substituents selected from the group consisting of -O-alkyl, -OH, -F, -Cl, -Br and -I, where alkyl is preferably methyl, ethyl, propyl or isopropyl. More preferably, the phenyl radicals are each independently substituted, in each case by one or more substituents selected from the group consisting of -O-Me, -OH, -F, -Cl, -Br and -I.

Further preferably, the spiro compound is a compound of the following formula:

where R^r , R^s , R^t , R^u , R^v , R^w , R^x and R^y are each independently selected from the group consisting of -O-alkyl, -OH, -F, -Cl, -Br and -I, where alkyl is preferably methyl, ethyl, propyl or isopropyl. More preferably, R^r , R^s , R^t , R^u , R^v , R^w , R^x and R^y are each independently selected from the group consisting of -O-Me, -OH, -F, -Cl, -Br and -I.

More particularly, the p-type semiconductor may comprise spiro-MeOTAD or consist of spiro-MeOTAD, i.e. a compound of the formula below, commercially available, for example, from Merck KGaA, Darmstadt, Germany:

Alternatively or additionally, it is also possible to use other p-semiconducting compounds, especially low molecular weight and/or oligomeric and/or polymeric p-semiconducting compounds.

In an alternative embodiment, the low molecular weight organic p-type semiconductor comprises one or more compounds of the abovementioned general formula I, for which reference may be made, for example, to PCT application number PCT/EP2010/051826, which will be published after the priority date of the present application. The p-type semiconductor may comprise the at least one compound of the abovementioned general formula I additionally or alternatively to the spiro compound described above.

The term "alkyl" or "alkyl group" or "alkyl radical" as used in the context of the present invention is understood to mean substituted or unsubstituted C₁-C₂₀-alkyl radicals in general. Preference is given to C₁- to C₁₀-alkyl radicals, particular preference to C₁- to C₈-alkyl radicals. The alkyl radicals may be either straight-chain or branched. In addition, the alkyl radicals may be substituted by one or more substituents selected from the group consisting of C₁-C₂₀-alkoxy, halogen, preferably F, and C₆-C₃₀-aryl which may in turn be substituted or unsubstituted. Examples of suitable alkyl groups are methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl and octyl, and also isopropyl, isobutyl, isopentyl, sec-butyl, tert-butyl, neopentyl, 3,3-dimethylbutyl, 2-ethylhexyl, and also derivatives of the alkyl groups mentioned substituted by C₆-C₃₀-aryl, C₁-C₂₀-alkoxy and/or halogen, especially F, for example CF₃.

The term "aryl" or "aryl group" or "aryl radical" as used in the context of the present invention is understood to mean optionally substituted C₆-C₃₀-aryl radicals which are derived from monocyclic, bicyclic, tricyclic or else multicyclic aromatic rings, where the aromatic rings do not comprise any ring heteroatoms. The aryl radical preferably comprises 5- and/or 6-membered aromatic rings. When the aryls are not monocyclic systems, in the case of the term "aryl" for the second ring, the saturated form (perhydro form) or the partly unsaturated form (for example the dihydro form or tetrahydro form), provided the particular forms are known and stable, is also possible. The term "aryl" in the context of the present invention thus comprises, for example, also bicyclic or tricyclic radicals in which either both or all three radicals are aromatic, and also bicyclic or tricyclic radicals in which only one ring is aromatic, and also tricyclic radicals in which two rings are aromatic. Examples of aryl are: phenyl, naphthyl, indanyl, 1,2-dihydronaphthenyl, 1,4-dihydronaphthenyl, fluorenyl, indenyl, anthracenyl, phenanthrenyl or 1,2,3,4-tetrahydronaphthyl. Particular preference is given to C₆-C₁₀-aryl radicals, for example phenyl or naphthyl, very particular preference to C₆-aryl radicals, for example phenyl. In addition, the term "aryl" also comprises ring systems comprising at least two monocyclic, bicyclic or multicyclic aromatic rings joined to one another via single or double bonds. One example is that of biphenyl groups.

The term "heteroaryl" or "heteroaryl group" or "heteroaryl radical" as used in the context of the present invention is understood to mean optionally substituted 5- or 6-membered aromatic rings and multicyclic rings, for example bicyclic and tricyclic compounds having at least one heteroatom in at least one ring. The heteroaryls in the context of the invention preferably comprise 5 to 30 ring atoms. They may be monocyclic, bicyclic or tricyclic, and some can be derived from the aforementioned aryl by replacing at least one carbon atom in the aryl base skeleton with a heteroatom. Preferred heteroatoms are N, O and S. The hetaryl radicals more preferably have 5 to 13 ring atoms. The base skeleton of the heteroaryl radicals is especially preferably selected from systems such as pyridine and five-membered heteroaromatics such as thiophene, pyrrole, imidazole or furan. These base skeletons may optionally be fused to one or two six-membered aromatic radicals. In addition, the term "heteroaryl" also comprises ring systems comprising at least two monocyclic, bicyclic or multicyclic aromatic rings joined to one another via single or double bonds, where at least one ring comprises a heteroatom. When the heteroaryls are not monocyclic systems, in the case of the term "heteroaryl" for at least one ring, the saturated form (perhydro form) or the partly unsaturated form (for example the dihydro form or tetrahydro form), provided the particular forms are known and stable, is also possible. The term "heteroaryl" in the context of the present invention thus comprises, for example, also bicyclic or tricyclic radicals in which either both or all three radicals are aromatic, and also bicyclic or tricyclic radicals in which only one ring is aromatic, and also tricyclic radicals in which two rings are aromatic, where at least one of the rings, i.e. at least one aromatic or one nonaromatic ring has a heteroatom. Suitable

fused heteroaromatics are, for example, carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl. The base skeleton may be substituted at one, more than one or all substitutable positions, suitable substituents being the same as have already been specified under the definition of C₆-C₃₀-aryl. However, the hetaryl radicals are preferably unsubstituted. Suitable hetaryl radicals are, for example, pyridin-2-yl, pyridin-3-yl, pyridin-4-yl, thiophen-2-yl, thiophen-3-yl, pyrrol-2-yl, pyrrol-3-yl, furan-2-yl, furan-3-yl and imidazol-2-yl and the corresponding benzofused radicals, especially carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl.

In the context of the invention the term "optionally substituted" refers to radicals in which at least one hydrogen radical of an alkyl group, aryl group or heteroaryl group has been replaced by a substituent. With regard to the type of this substituent, preference is given to alkyl radicals, for example methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl and octyl, and also isopropyl, isobutyl, isopentyl, sec-butyl, tert-butyl, neopentyl, 3,3-dimethylbutyl and 2-ethylhexyl, aryl radicals, for example C₆-C₁₀-aryl radicals, especially phenyl or naphthyl, most preferably C₆-aryl radicals, for example phenyl, and hetaryl radicals, for example pyridin-2-yl, pyridin-3-yl, pyridin-4-yl, thiophen-2-yl, thiophen-3-yl, pyrrol-2-yl, pyrrol-3-yl, furan-2-yl, furan-3-yl and imidazol-2-yl, and also the corresponding benzofused radicals, especially carbazolyl, benzimidazolyl, benzofuryl, dibenzofuryl or dibenzothiophenyl. Further examples include the following substituents: alkenyl, alkynyl, halogen, hydroxyl.

The degree of substitution here may vary from monosubstitution up to the maximum number of possible substituents.

Preferred compounds of the formula I for use in accordance with the invention are notable in that at least two of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. The at least two radicals here may be only -OR radicals, only -NR₂ radicals, or at least one -OR and at least one -NR₂ radical.

Particularly preferred compounds of the formula I for use in accordance with the invention are notable in that at least four of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. The at least four radicals here may be only -OR radicals, only -NR₂ radicals or a mixture of -OR and -NR₂ radicals.

Very particularly preferred compounds of the formula I for use in accordance with the invention are notable in that all of the R¹, R² and R³ radicals are para-OR and/or -NR₂ substituents. They may be only -OR radicals, only -NR₂ radicals or a mixture of -OR and -NR₂ radicals.

In all cases, the two R in the $-NR_2$ radicals may be different from one another, but they are preferably the same.

Preferably, A^1 , A^2 and A^3 are each independently selected from the group consisting of

5

in which

10

m is an integer from 1 to 18,

R^4 is alkyl, aryl or heteroaryl, where R^4 is preferably an aryl radical, more preferably a phenyl radical,

15

R^5 , R^6 are each independently H, alkyl, aryl or heteroaryl,

where the aromatic and heteroaromatic rings of the structures shown may optionally have further substitution. The degree of substitution of the aromatic and heteroaromatic rings here may vary from monosubstitution up to the maximum number of possible substituents.

20

Preferred substituents in the case of further substitution of the aromatic and heteroaromatic rings include the substituents already mentioned above for the one, two or three optionally substituted aromatic or heteroaromatic groups.

25

Preferably, the aromatic and heteroaromatic rings of the structures shown do not have further substitution.

More preferably, A¹, A² and A³ are each independently

more preferably

5

More preferably, the at least one compound of the formula (I) has one of the following structures:

10

ID367

45

In an alternative embodiment, the organic p-type semiconductor comprises a compound of the type ID322 having the following structure:

5

The compounds for use in accordance with the invention can be prepared by customary methods of organic synthesis known to those skilled in the art. References to relevant (patent) literature can additionally be found in the synthesis examples adduced below.

10

Second electrode

The second electrode may be a bottom electrode facing the substrate or else a top electrode facing away from the substrate. The second electrode used can be especially metal electrodes which may have one or more metals in pure form or as a mixture/alloy, such as especially aluminum or silver. The use of inorganic/organic mixed electrodes or multilayer electrodes is also possible, for example the use of LiF/Al electrodes.

15

In addition, it is also possible to use electrode designs in which the quantum efficiency of the components is increased by virtue of the photons being forced, by means of appropriate reflections, to pass through the absorbing layers at least twice. Such layer structures are also referred to as "concentrators" and are likewise described, for example, in WO 02/101838 (especially pages 23-24).

The organic solar cell can furthermore comprise at least one encapsulation, wherein the encapsulation is designed to shield the organic solar cell, in particular the electrodes and/or the p-type semiconductor, from a surrounding atmosphere.

Overall, in the context of the present invention, the following embodiments are regarded as particularly preferred:

Embodiment 1: A detector for optically detecting at least one object, comprising at least one optical sensor, wherein the optical sensor has at least one sensor region, in particular at least one sensor region comprising at least one sensor area wherein the optical sensor is designed to generate at least one sensor signal in a manner dependent on an illumination of the sensor region, wherein the sensor signal, given the same total power of the illumination is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area, wherein the detector furthermore has at least one evaluation device, wherein the evaluation device is designed to generate at least one item of geometrical information from the sensor signal, in particular at least one item of geometrical information about the illumination and/or the object.

Embodiment 2: The detector according to the preceding embodiment, wherein the detector furthermore has at least one modulation device for modulating the illumination.

Embodiment 3: The detector according to the preceding embodiment, wherein the detector is designed to detect at least two sensor signals in the case of different modulations, in particular at least two sensor signals at respectively different modulation frequencies, wherein the evaluation device is designed to generate the geometrical information from the at least two sensor signals.

Embodiment 4: The detector according to any of the preceding embodiments, wherein the optical sensor is furthermore designed in such a way that the sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination.

Embodiment 5: The detector according to any of the preceding embodiments, wherein the sensor region is exactly one continuous sensor region, wherein the sensor signal is a uniform sensor signal for the entire sensor region.

- 5 Embodiment 6: The detector according to any of the preceding embodiments, wherein the sensor signal is selected from the group consisting of a photocurrent and a photovoltage.

10 Embodiment 7: The detector according to any of the preceding embodiments, wherein the optical sensor comprises at least one semiconductor detector, in particular an organic semiconductor detector comprising at least one organic material, preferably an organic solar cell and particularly preferably a dye solar cell, in particular a solid dye solar cell.

15 Embodiment 8: The detector according to the preceding embodiment, wherein the optical sensor comprises at least one first electrode, at least one n-semiconducting metal oxide, at least one dye, at least one p-semiconducting organic material, preferably a solid p-semiconducting organic material, and at least one second electrode.

20 Embodiment 9: The detector according to any of the preceding embodiments, wherein the geometric information comprises at least one item of location information of the object.

25 Embodiment 10: The detector according to the preceding embodiment, wherein the evaluation device is designed to determine the geometrical information from at least one predefined relationship between the geometry of the illumination and a relative positioning of the object with respect to the detector, preferably taking account of a known power of the illumination and optionally taking account of a modulation frequency with which the illumination is modulated.

30 Embodiment 11: The detector according to any of the preceding embodiments, furthermore comprising at least one transfer device, wherein the transfer device is designed to feed electromagnetic radiation emerging from the object to the optical sensor and thereby to illuminate the sensor region.

35 Embodiment 12: The detector according to any of the preceding embodiments, furthermore comprises at least one illumination source.

40 Embodiment 13: The detector according to the preceding embodiment, wherein the illumination source is selected from: an illumination source, which is at least partly

connected to the object and/or is at least partly identical to the object; an illumination source which is designed to at least partly illuminate the object with a primary radiation.

5 Embodiment 14: A distance measuring device, in particular for use in a motor vehicle, comprising at least one detector according to any of the preceding
embodiments, wherein the detector is designed to determine at least one item of
geometrical information of at least one object, wherein the geometrical information
comprises at least one item of location information of the object, in particular a distance
between a motor vehicle and at least one object and preferably a distance between the
10 motor vehicle and at least one object selected from the group consisting of a further
motor vehicle, an obstacle, a cyclist and a pedestrian.

Embodiment 15: An imaging device for imaging at least one sample, wherein the
imaging device comprises at least one detector according to any of the preceding
15 embodiments relating to a detector, wherein the imaging device is designed to image a
plurality of partial regions of the sample onto the sensor region and to thereby generate
sensor signals assigned to the partial regions, wherein the imaging device is designed to
generate items of geometrical information of the respective partial regions from the
sensor signals, wherein the items of geometrical information comprise items of location
20 information.

Embodiment 16: A human-machine interface for exchanging at least one item of
information between a user and a machine, in particular for inputting control commands,
wherein the human-machine interface comprises at least one detector according to any
25 of the preceding claims relating to a detector wherein the human-machine interface is
designed to generate at least one item of geometrical information of the user (218) by
means of the detector wherein the human-machine interface is designed to assign to the
geometrical information at least one item of information, in particular at least one control
command.

30 Embodiment 17: An entertainment device for carrying out at least one entertainment
function, in particular a game, wherein the entertainment device comprises at least one
human-machine interface according to the preceding embodiment, wherein the
entertainment device is designed to enable at least one item of information to be input by
35 a player by means of the human-machine interface, wherein the entertainment device is
designed to vary the entertainment function in accordance with the information.

Embodiment 18: A security device for carrying out at least one security application in
particular for identifying and/or avoiding an access to data of an optical data storage
40 device, wherein the security device comprises at least one detector according to any of
the preceding embodiments relating to a detector, wherein the security device is

designed to identify, by means of the detector, impingement of focused electromagnetic radiation, in particular laser beams, on the security device and preferably to generate at least one warning signal.

- 5 Embodiment 19: A method for optically detecting at least one object, in particular using a detector according to any of the preceding embodiments relating to a detector, wherein at least one optical sensor is used, wherein the optical sensor has at least one sensor region, wherein electromagnetic radiation emerging from the object is fed to the optical sensor and thereby the sensor region is illuminated, wherein the optical sensor
10 generates at least one sensor signal in a manner dependent on the illumination of the sensor region, wherein the sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination.

- Embodiment 20: The method according to the preceding embodiment, wherein at
15 least one item of geometrical information of the object is generated from the sensor signal, in particular at least one item of location information of the object.

- Embodiment 21: The use of a detector according to any of the preceding
embodiments relating to a detector for a purpose of use, selected from the group
20 consisting of: distance measurement, in particular in traffic technology; imaging, in particular in microscopy; an entertainment application; a security application; a human-machine interface application.

- Embodiment 22: The use of an organic solar cell, in particular a dye solar cell,
25 preferably a solid dye solar cell, as optical sensor, wherein at least one sensor signal is generated in the use, wherein the sensor signal, given the same total power of an illumination is dependent on a geometry of the illumination on the organic solar cell, wherein at least one item of geometrical information of at least one object is generated from the sensor signal in the use.

30

Brief description of the figures

- Further optional details and features of the invention are evident from the description of preferred exemplary embodiments which follows in conjunction with the dependent
35 claims. In this context, the particular features may be implemented alone or with several in combination. The invention is not restricted to the exemplary embodiments. The exemplary embodiments are shown schematically in the figures. Identical reference numerals in the individual figures refer to identical elements or elements with identical function, or elements which correspond to one another with regard to their functions.

40

Specifically, in the figures:

- 5 figure 1 shows an exemplary embodiment of a detector according to the invention for optically detecting at least one object;
- figure 2 shows an exemplary embodiment of an optical sensor for use in a detector according to the invention;
- 10 figure 3 shows an exemplary embodiment of possible energy levels of a layer structure of an optical sensor in accordance with figure 2;
- figure 4 shows an exemplary embodiment of a signal dependence of an optical sensor according to the present invention on a beam geometry;
- 15 figures 5 and 6 show measurements for demonstrating a geometry independence of the sensor signals of conventional semiconductor sensors;
- figure 7 shows a typical frequency dependence of the signal of optical sensors for use in a detector according to the present invention;
- 20 figure 8 shows a joint illustration of the dependence of a sensor signal of the detector according to the present invention on a modulation frequency f and a beam geometry;
- 25 figure 9 shows a schematic exemplary embodiment of a distance measuring device according to the invention;
- figure 10 shows a result of a distance measurement using a distance measuring device according to the invention;
- 30 figure 11 shows a use of a distance measuring device according to the invention in motor vehicles;
- 35 figures 12A and 12B show a comparison of a conventional imaging device (figure 12A) having a confocal beam path with an imaging device according to the invention (figure 12B);
- 40 figures 13 and 14 show further possible embodiments of imaging devices according to the invention;

figure 15 shows an exemplary embodiment of a human-machine interface and of an entertainment device according to the present invention; and

figure 16 shows an exemplary embodiment of a security device according to the invention.

Exemplary embodiments

Detector

Figure 1 illustrates, in a highly schematic illustration, an exemplary embodiment of a detector 110 according to the invention for optically detecting at least one object 112. The detector 110 comprises an optical sensor 114, having a sensor region 116, for example having a sensor area 118. The sensor is designed to generate at least one sensor signal which can comprise for example a photocurrent I. By way of example, the optical sensor 114 can comprise at least one measuring device 120 by means of which at least one physical property of the optical sensor 114 can be detected, for example by at least one photocurrent and/or at least one photovoltage being measured.

Furthermore, the detector 110 in accordance with the exemplary embodiment illustrated in figure 1 comprises an evaluation device 122, which, by way of example, can be connected to the optical sensor 114 and/or else can be wholly or partly integrated into the optical sensor 114, or vice-versa. Said evaluation device 122 can be designed, for example, to pick up the at least one sensor signal of the optical sensor 114 directly or indirectly. The evaluation device 122 can comprise for example at least one data processing device 124 and/or at least one data storage device 126. Furthermore, the evaluation device 122 can have for example a unidirectional or bidirectional interface 128, for example in order to be able to exchange data and/or control commands unidirectionally or bidirectionally with other devices.

Furthermore, in the exemplary embodiment illustrated in figure 1, the detector 110 optionally comprises at least one transfer device 130, for example having at least one lens 132 and/or other imaging or non-imaging elements. The optional transfer device 130 is designed to feed electromagnetic radiation 134 emerging from the object 112 to the optical sensor 114 and to illuminate the sensor region 116 in the process. By way of example, a light spot 136 having a diameter or equivalent diameter can arise on the sensor area 118 in this way. Said light spot 136 can have an area A, for example, wherein the total power of the electromagnetic radiation 134 is designated by p in figure 1, and the flux p/A is designated by Φ . It is pointed out that the optional transfer device

130 in figure 1 is only indicated schematically. Said transfer device can also be embodied in various other ways.

Furthermore, in the exemplary embodiment in accordance with figure 1, the detector 110 optionally comprises at least one modulation device 138 for modulating the electromagnetic rays 134. In particular, said modulation device 138 can comprise at least one beam interrupter 140, for example a so-called chopper wheel.

Furthermore, the detector 110 can optionally comprise at least one illumination source 142. Said illumination source 142 can be designed to irradiate the object 112 or a partial region of the object 112 with a primary radiation 144. By way of example, said primary radiation 144 can be reflected and/or scattered at the object 112. During this reflection and/or scattering, which can be supported for example by at least one optional reflective surface 146 of the object 112, the electromagnetic radiation 134 is optionally generated, which is then fed to the optical sensor 114, for example by means of the transfer device 130. As an alternative or in addition to reflection and/or scattering, however, the primary radiation 144 can also excite the object 112 or a part thereof to emit the electromagnetic radiation 134, for example in the form of an excitation of fluorescence and/or excitation of phosphorescence. In this case, the object 112 can comprise for example at least one fluorescent material and/or at least one phosphorescent material.

Optical sensor

As explained above, it is particularly preferred if the optical sensor 114 comprises at least one semiconductor detector 148, in particular an organic semiconductor detector 150, preferably an organic solar cell 152 and particularly preferably a dye solar cell 154. An exemplary embodiment of such optical sensors 114 is shown in figure 2 in a schematic sectional illustration through one possible layer structure. The dye solar cell 154 illustrated there can comprise for example a substrate 156, for example a glass substrate. However, other substrates 156 can also be used, as described above, for example a plastic substrate or else multilayer or laminate substrates. In the exemplary embodiment illustrated, at least one first electrode 158, which can also be designated as a working electrode and which can preferably be embodied in a transparent fashion, as described above, is applied on said substrate 156. At least one blocking layer 160 (also designated hereinafter as buffer layer) of an optional metal oxide can in turn optionally be applied on said first electrode 158, said layer preferably being nonporous and/or nonparticulate. An n-semiconducting metal oxide 162 is applied in turn on said layer, said metal oxide being sensitized with a dye 164. As explained above, this sensitization can be effected by applying a separate layer of the dye 164 and/or by complete or partial impregnation, wetting or mixing of the, preferably porous and/or particulate, n-semiconducting metal oxide 162 with the dye 164.

An organic p-type semiconductor 166 is applied to the dye 164. Said organic p-type semiconductor 166 is preferably solid in the finished state of the dye solar cell 154, that is to say embodied as a solid organic p-type semiconductor 166. A plurality of layers of this solid organic p-type semiconductor 166 can also be provided. A second electrode 168, which is also designated as a counterelectrode, is applied on the p-type semiconductor 166.

The layers illustrated in figure 2 together form a layer structure 170, which is preferably shielded from a surrounding atmosphere by an encapsulation 172, for example in order to shield the layer structure 170 from a surrounding atmosphere, for example in order to completely or partly protect the layer structure 170 from oxygen and/or moisture. One or both of the electrodes 158, 168 or connection contacts of said electrodes 158, 168 can be led out from the encapsulation 172, in order to be able to provide one or a plurality of contact-connection areas outside the encapsulation 172.

Figure 3 shows, in a highly schematic manner, one possible energy level diagram of the dye solar cell 154, for example according to figure 2. The illustration shows the Fermi levels 174 of the first electrode 158 and of the second electrode 168, and the HOMOs (Highest Occupied Molecular Orbitals) 176 and the LUMOs (Lowest Unoccupied Molecular Orbitals) 178 of the layers 160, 162 (which can comprise the same material, for example TiO_2) of the dye 164 (indicated by way of example, with a HOMO level of 5.7 eV) and of the p-type semiconductor 166 (also designated as HTL, Hole Transport Layer). FTO (fluorine-doped tin oxide) and silver are specified by way of example as materials for the first electrode 158 and the second electrode 168. It is pointed out that other electrode materials can also be used and that, for example, the order of the first electrode and the second electrode can also be reversed and that, for example, it is also possible to use a nontransparent substrate 156 in combination with a transparent second electrode 168 and optionally a transparent encapsulation 172, or an inverse layer structure. The organic semiconductor detector 150 can furthermore optionally comprise further elements that are not illustrated in figures 2 and 3.

Production of a dye solar cell

As an example of production of an organic solar cell 152, production of a dye solar cell 154 with a solid p-type semiconductor 166 is described below by way of example.

As the base material and substrate 156, glass plates which had been coated with fluorine-doped tin oxide (FTO) as the first electrode (working electrode) 158 and were of dimensions 25 mm × 25 mm × 3 mm (Hartford Glass) were used, which were treated successively in an ultrasound bath with glass cleaner (RBS 35), demineralized water and

acetone, for 5 min in each case, then boiled in isopropanol for 10 min and dried in a nitrogen stream.

To produce an optional solid TiO₂ buffer layer 160, a spray pyrolysis process was used. Thereon, as an n-semiconducting metal oxide 162, a TiO₂ paste (Dyesol) which comprises TiO₂ particles with a diameter of 25 nm in a terpeneol/ethylcellulose dispersion was spun on with a spin-coater at 4500 rpm and dried at 90°C for 30 min. After heating to 450°C for 45 min and a sintering step at 450°C for 30 minutes, a TiO₂ layer thickness of approximately 1.8 μm was obtained.

After removal from the drying cabinet, the sample was cooled to 80°C and immersed into a 5 mM solution of an additive ID662 (obtainable according to example H below, for example) for 12 h and subsequently into a 0.5 mM solution of a dye 164 in dichloromethane for 1 h. The dye 164 used was the dye ID504 (obtainable according to example G below, for example), but a large number of other dyes can be used and the choice of dye generally has only little influence on the effect described above. In particular, the dye can be adapted to the respective purpose of use and the wavelengths of the electromagnetic radiation 134 used.

ID662

ID504

After removal from the solution, the sample was subsequently rinsed with the same solvent and dried in a nitrogen stream. The samples obtained in this way were subsequently dried at 40°C under reduced pressure.

Next, a p-type semiconductor 166 solution was spun on. For this purpose, a solution of 0.163 M spiro-MeOTAD (Merck) and 20 mM LiN(SO₂CF₃)₂ (Aldrich) in chlorobenzene

was made up. 125 μ l of this solution were applied to the sample and allowed to act for 60 s. Thereafter, the supernatant solution was spun off at 2000 rpm for 30 s.

Finally, a metal back electrode was applied as a second electrode 168 by thermal metal vaporization under reduced pressure. The metal used was Ag, which was vaporized at a rate of 3 $\text{\AA}/\text{s}$ at a pressure of approx. $2 \cdot 10^{-6}$ mbar, so as to give a layer thickness of about 200 nm.

Dependence of the sensor signal on the geometry of the illumination and the modulation frequency

With such dye solar cells 154 as optical sensor 114, firstly the method of operation of the detector 110 illustrated in figure 1 will be described. Figure 4 shows an example of a measurement of a photocurrent I (normalized to the maximum value) as a function of a position x (indicated in millimeters) of a lens 132, wherein the lens 132 focuses electromagnetic radiation 134 onto a sensor area 118 of the dye solar cell 154. The sensor area 118 can be for example a surface of the substrate 156 of the layer structure in figure 2, said surface facing away from the first electrode 158. Alternatively, however, the sensor area 118 can also be arranged in a layer plane of the organic layer structure, for example in the region of the dye 164. The exact position of said sensor area 118 within the organic semiconductor detector 150 is greatly dependent on the individual physical processes and is generally not of importance for the exact functioning of the detector 110. Alternatively, the entire organic layer structure or a part thereof can be regarded as a sensor region 116.

During the measurement in figure 4, the lens 132 is displaced relative to the optical sensor 114 in figure 1 in a direction perpendicular to the sensor area 118. As a result, the diameter or equivalent diameter of the light spot 136 on the sensor area 118 changes. By way of example, a lens having a focal length of 50 mm can be used, given a beam diameter of 25 mm, for example, which leads to a size of the light spot 136 of less than 2 mm, for example. A location of the lens 132 at which optimum focusing occurs is arbitrarily indicated as location $x = 0$ in figure 4. As an alternative or in addition to a displacement of the lens 132 or alteration of the optional transfer device 130, other measures could also be implemented in order to vary a focusing of the electromagnetic radiation 134 on the sensor area 118 or a diameter or equivalent diameter or some other geometry of the electromagnetic radiation 134 in the sensor region 116 and in particular on the sensor area 118.

It can clearly be discerned in figure 1 that the signal of the optical sensor 114, in this case the photocurrent, is greatly dependent on the geometry of the illumination. Outside a maximum at $x = 0$, the photocurrent falls to less than 10% of its maximum value.

In comparison therewith, figures 5 and 6 illustrate corresponding measurements on silicon diodes (figure 5) and germanium diodes (figure 6). In this case, diodes of the Hamamatsu S2386-8k type were used as silicon diodes, and diodes of the Hamamatsu J16-5SP-R03M type were used as germanium diodes. It can clearly be discerned that the signal of such semiconductor diodes, apart from marginal effects in figure 6, which may be attributable to a boundary of the sensor area, and apart from noise effects, which are below 10%, does not have the above-described geometry dependence of the sensor signals on the illumination of the sensor region 116. In other words, in the case of the optical sensors 114 of a conventional type that are used in figures 5 and 6, the sensor signal, given the same total power, is substantially independent of a geometry of the illumination of the sensor region 116 or the sensor area 118; wherein, by way of example, fluctuations of less than 10%, preferably of less than 5%, can still be accepted and should not yet be regarded as the effect according to the invention. In contrast thereto, the measurement by means of the detector 110 according to the invention and the optical sensor 114 in accordance with figure 2, for example, shows a pronounced geometry-dependent effect in the sensor signal.

This effect is generally dependent on a modulation frequency of the illumination of the optical sensor 114. The measurements in figures 4-6 were carried out using a modulation device 138 by means of which the electromagnetic radiation 134 was modulated before impinging on the sensor region 116 with a frequency of typically 30 Hz to 100 Hz. The modulation device 138 used was an electronic modulation device in the form of a pulsed current source having a duty cycle of 1:1. This is illustrated once again schematically in figure 7 for measurements analogous to the measurement in accordance with figure 4. Here the sensor signal I/I_0 , that is to say the sensor signal normalized to its maximum value I_0 , is plotted as a function of the spatial coordinate x of the lens 132 used for the focusing, but this can be exchanged, in principle, for any other parameter that characterizes the geometry of the illumination on the sensor region 116 or the sensor area 118. The illustration schematically shows a curve of the sensor signal at a modulation frequency $f = 0$ Hz and a modulation frequency f that is greater than a limiting frequency f_{Base} dependent on the type of optical sensor 114.

From the spatial coordinate x it is possible, by using imaging equations or else by simple observation, for example, to deduce the geometry of the illumination. On the other hand it is possible, for example given fixed positioning of the lens 132 or fixed embodiment of the transfer device 130, to deduce for example at least one spatial coordinate of the object 112 from the sensor signal and/or from the geometry of the illumination. For this purpose, calibration curves can be recorded and/or calculated, which can be stored for example in the evaluation device 122 and/or the data storage device 126. Figure 8 shows one possible example of such calibration curves in a three-dimensional

illustration. Here the photocurrent I is plotted as a function of the spatial coordinate x of the lens 132 and as a function of the modulation frequency f , specified in hertz. During this measurement, a photocurrent of 7 nA occurred as maximum photocurrent. In this case, the location of the maximum is chosen arbitrarily, and so in this case, without
5 restricting the usability of the results, the location $x = 0$ does not specify the location of the maximum. The curves clearly show that the sensor signal I is a distinct function of the spatial coordinate x , and hence the geometry of the illumination of the sensor region 116, and the frequency f .

10 In a manner similar to that illustrated in figure 8, a multiplicity of other calibration curves can be recorded. By way of example, it is possible to record calibration curves in which, instead of the spatial coordinate x , a coordinate is directly specified which characterizes at least one item of geometrical information of the object 112. Given a known modulation frequency f and measured intensity I , there is then only an ambiguity with regard to the
15 fact of on which side of the maximum the measurement result lies. This ambiguity can be resolved for example by prior knowledge of on which side of the maximum the measurement must lie, or by a plurality of measurements. The evaluation device 122 can be designed to resolve this ambiguity, for example by programming.

20 Distance measuring device

Figure 9 shows a highly schematic example of a distance measuring device 180, which in principle, can be embodied analogously to the detector 110 in accordance with figure 1 and/or can comprise such a detector 110. In this case, the at least one item of
25 geometrical information generated by means of the detector is embodied as location information or comprises at least one item of location information, and/or the distance measuring device 180 is designed to generate the at least one item of location information from the at least one item of geometrical information. The distance measuring device 180 therefore serves to generate at least one item of location
30 information about at least one object 112, which is illustrated symbolically as a pedestrian in figure 9. By way of example, this location information can comprise at least one distance d_1 or d_2 between the object 112 and the detector 110 or a part of the detector 110, for example a distance between the object 112 and a lens 132 of the detector 110.

35 The structure of the detector 110 in figure 9 can correspond, in principle, to the structure in accordance with figure 1. An optional modulation device 138, which can be arranged for example between object 112 and lens 132 and/or between lens 132 and optical sensor 114 and/or which can be integrated into the at least one illumination source 142, is not illustrated in figure 9.
40

Figure 9 illustrates by way of example two objects 112 at different distances d_1 , d_2 . These cause for example on the sensor region 116, and in particular the sensor area 118, different light spots 182, 184, with different geometries. Sensor signals which are picked up by the optical sensor 114 in accordance with the geometry of said light spots 182, 184 are correspondingly different. The evaluation device 122 can be designed, for example using calibration curves in accordance with figure 5 and/or other types of calibration curves, to generate from said sensor signals an item of geometrical information, in particular at least one item of location information, of the object 112, for example an item of information about the distance d_1 or d_2 between the objects 112 and the detector 110.

The detector 110 or distance measuring device 180 can be embodied for example in integral fashion or else in a multipartite fashion and can comprise for example at least one housing 186 into which, by way of example, the optical sensor 114 and/or the evaluation device 122 and optionally the at least one illumination source 142 can be integrated. Alternatively or additionally, however, it is also possible to provide multipartite embodiments, for example by one or a plurality of illumination sources 142 being arranged separately, for example in a separate housing. Overall, the distance measuring device 180 in accordance with figure 9 can have for example the form of a simple, camera-like arrangement and can for example also be embodied as a handheld device, that is to say as a device which can be carried by a user or can be taken along solely on the basis of muscle power. Various other configurations are possible.

The distance measuring device 180 in accordance with figure 9 can optionally comprise exactly one optical sensor 114. Alternatively, the distance measuring device 180 can also be embodied as a camera, for example by a plurality of optical sensors 114 and/or one or a plurality of optical sensors 114 having a plurality of sensor regions 116 being used, for example in a two-dimensional matrix arrangement and/or a three-dimensional matrix arrangement. One advantage of such cameras resides, in comparison with conventional recording techniques, in a shorter recording time, for example with a pixel clock of 10 MHz, corresponding to a time of 0.1 ms for 1000 pixels. Recording times for two-dimensional and three-dimensional recordings can generally be made equally short. In contrast thereto, conventional cameras, in order to generate three-dimensional images, generally have to record n images, which necessitates recording times in the Hz - kHz range. Furthermore, conventional cameras of the type mentioned are generally of comparatively low luminosity.

Evidence of the functioning of the arrangement illustrated in figure 9 is shown in figure 10. Here a distance x_M (corresponding, for example, to the spatial coordinates d_1 and d_2 in figure 9), specified in cm or 10 mm, measured by means of the distance measuring device 180 in accordance with figure 9 is plotted as a function of the actual distance x_s ,

likewise specified in cm or 10 mm. The measurements were carried out using a transfer device 130 in the form of an objective having an achromatic lens, an illumination source 142 in the form of a frequency-doubled neodymium laser and a dye solar cell 154 in accordance with the above description having a sensor area 118 of approximately 4 mm².

The measurements clearly show that, for example here in the case of distances of less than 1 m, the distance measurements by means of the distance measuring device 180 according to the invention correspond excellently to the actual distances. The distance measurement is readily also adaptable to other distances, for example by adapting the transfer device 130 and/or the illumination source 142 and/or the optical sensor 114. By way of example, microscopic distances can be identified by corresponding focusing of the primary radiation 144 and/or by corresponding embodiment of the optional transfer device 130. Greater distances than the distances shown in figure 10 can likewise be identified for example by using laser beams and/or corresponding optics in the transfer device 130. However, the measurement in figure 10 clearly shows that the measurement principle proposed can be realized.

This measurement principle of a distance measuring device 180 can be used very diversely, for example for determining at least one spatial coordinate of at least one object 112, of a plurality of objects, or for spatially detecting an entire environment, for example in a scanning method in which, within a visual range of the detector 110, one or a plurality of objects, a plurality of points of at least one object or contours of one or a plurality of objects are detected successively or simultaneously. In this respect, the distance measuring device 180 in the embodiment illustrated or another embodiment according to the invention can be used and embodied very diversely and can be used for example generally for one-dimensional, for two-dimensional or for three-dimensional detection of surroundings.

Figure 11 shows how a distance measuring device 180 of the type proposed can be used for example in motor vehicle technology, for example for detecting the surroundings. By way of example, a detector 110 or a part thereof can be arranged on a front side 188 of a first motor vehicle 190. An illumination source 142, for example in the form of an infrared transmitter, which directly emits the electromagnetic radiation 134 in the direction of the detector 110, can be arranged on a rear side 192 of a second motor vehicle 194, which in this case can function as the object 112. Said illumination source 142 can therefore be regarded as a constituent part of the detector 110 or else as a separate component. Alternatively or additionally, the at least one illumination source 142 or a part thereof could, however, also be arranged in the first motor vehicle 190 and emit primary radiation in the direction of the second motor vehicle 194, where it is for example reflected and/or scattered and/or excites luminescence, such that

electromagnetic radiation 134 in turn propagates back to the first motor vehicle 190 and the detector 110. Various embodiments are possible.

Generally, the illumination can be embodied in such a way that a geometry of an illumination of a sensor region 116 of the detector 110 changes with a distance d between the motor vehicles 190, 194. This can be effected for example once again by means of a corresponding embodiment of the illumination source 142 and/or an optional transfer device 130 of the detector 110. Consequently, a sensor signal of the detector 110 also changes, from which the distance d and/or some other geometrical information can in turn be deduced. This deduction can be effected for example once again by using one or a plurality of calibration functions, in particular once again by means of an evaluation device 122. The latter can be embodied separately, but can also be integrated for example wholly or partly into a device already present in the motor vehicle, for example an engine controller.

By way of example, a plurality of motor vehicles 190, 194 can each be equipped with such distance measuring devices 180. The at least one item of geometrical information, in particular the at least one item of location information, about the motor vehicle ahead and/or the following motor vehicle can for example be brought to the attention of a driver and/or used to generate warning signals and/or to intervene automatically in a driving behavior of the motor vehicle.

The structure shown in figure 11 can be modified in diverse ways in the context of the present invention. Thus, by way of example, the at least one illumination source 142 can also be integrated directly into the detector 110, such that, by way of example, as described above, the detector 110 can emit primary radiation 144 in the direction of, for example, another motor vehicle, in particular a motor vehicle ahead. Said radiation can then be for example reflected and/or scattered and/or used for excitation there and can be directed as electromagnetic radiation 134 back to the detector 110 again. Thus, by way of example, motor vehicles could also be equipped with one or a plurality of reflectors which can foster this reflection process. Furthermore, generally the at least one detector can be embodied for carrying out monitoring of the surroundings of a motor vehicle, for example by a viewing direction of the detector 110 and/or a radiation direction of the primary radiation 144 being made variable. Various other embodiments are conceivable.

In contrast for example to conventional triangulation methods, propagation time methods, image evaluation methods or similar methods for identifying distances, the detector 110 according to the invention and the distance measuring device 180 according to the invention afford the advantage of a simpler structure, in particular without the need for digital data analysis, a faster reaction and a more cost-effective embodiment.

Imaging device

Figures 12A-14 show that the detector 110 according to the invention can advantageously also be used in an imaging device 196 for imaging at least one sample 198. In this case, the sample 198 serves as the object 112. The measurement principle of the imaging device 196 can, in principle, be analogous, similar or even identical to the principle of the distance measuring device 180 described above, although (which is also possible, in principle, in the context of the distance measuring device 180) a plurality of points and/or regions of the at least one object 112 or of the sample 198 can be detected.

Figure 12A shows an imaging device 196 corresponding to the prior art in the form of a conventional confocal microscope having a confocal beam path. The confocal microscope has an illumination source 142, for example a laser, the focus of which is designated symbolically by the reference numeral 202 in figure 12A. Primary radiation 144 emerging from said illumination source 142 is directed by a beam splitter 204, for example a partly transmissive mirror and/or a beam splitter cube, onto the sample 198 and is focused for example by means of a lens 132 and/or an objective. Electromagnetic radiation 134 emerging from the sample 198 is directed by means of the beam splitter 204 onto a diaphragm 206, which is confocal with respect to the focus 202, and a sensor 208 lying behind said diaphragm. What is achieved by the confocal structure is that only light from the region of the image of the focus 202 can pass through the diaphragm 206 by means of the lens 132 in the sample 198 and can be detected by the sensor 208, for example a conventional semiconductor sensor. Light from other regions is at least substantially masked out by the diaphragm 206.

By contrast, figure 12B illustrates an exemplary embodiment of an imaging device 196 according to the invention. The structure can for example substantially correspond to the structure in accordance with figure 12A, but the diaphragm 206 can be obviated in that the sensor 208 can be replaced by an optical sensor 114 having the inventive properties of sensitivity relative to a geometry of the illumination of the sensor region 116.

From at least one known relationship between the sensor signal and at least one item of geometrical information (optionally by means of at least one intermediate step of determining a geometry of the illumination from the sensor signal and at least one optional intermediate step of determining the geometrical information from the geometry of the illumination), it is then possible to deduce from what depth of the sample 198 the electromagnetic radiation 134 originates. This can for example be effected once again by means of the evaluation device 122.

In this way, by way of example, an item of location information about the location of the origin of the electromagnetic radiation 134 can be generated, such that the sample 198 can be scanned, for example, and an item of information about a surface of the sample is in each case obtained, for example. Alternatively or additionally, it is also possible to obtain items of information from deeper regions of the sample 198. The optional transfer device 130 can comprise for example at least one scanning device, for example one or a plurality of movable mirrors, such that, for example, a line scan or else an area scan can be carried out on the sample 198. Such scanning devices are known for example from the field of confocal microscopy.

Furthermore, the optional transfer device 130 in the structure shown in figure 12B or else in other embodiments of devices and detectors 110 according to the invention can also comprise one or a plurality of wavelength-selective elements, for example wavelength-selective filters and/or wavelength-selective deflection elements such as, for example, one or a plurality of dichroic mirrors.

One advantage of the imaging device 196 illustrated in figure 12B in comparison with the conventional imaging device in accordance with figure 12A consists generally in a higher z-resolution, that is to say a higher resolution in the direction perpendicular to the sample 198, in a higher light intensity, since the need to use a diaphragm 206 is obviated, a higher insensitivity toward a transverse offset of an optical axis and the diaphragm 206, and a high intensity at an optimum z-resolution. Furthermore, the structure of the imaging device 196 according to the invention can be greatly simplified in comparison with conventional imaging devices 196, since generally, for example, by means of the detector 110, it is possible to generate not only an item of information about a total power of the electromagnetic radiation 134, but at least one item of geometrical information, for example at least one item of location information.

Figures 13 and 14 show modifications of the structure of the imaging device shown in figure 12B, once again in a highly schematic illustration. Thus, figure 13 shows a structure in which the detector 110 comprises a stack 210 of optical sensors 114. By way of example, the optical sensors 114 can be embodied such that they are fully or partly transparent. By means of these different sensors 114, which for example can in each case be aligned with the focus from a specific layer 212 or depth of the sample 198 or can be designed to receive signals corresponding to the electromagnetic radiation 134 emerging from said layer 212, a depth resolution in the z-direction perpendicular to the sample 198 can be automatically effected, without the optional transfer device 130 having to be designed for a movement in the z-direction. However, a scanning device parallel to the sample 198, which is designated by x, y in figures 13 and 14, can nevertheless still be provided, for example for carrying out a line or area scan.

Figure 14 shows a development of the exemplary embodiment in accordance with figure 13. This exemplary embodiment shows that in the detector 110 generally and in particular preferably in an imaging device 196, according to the invention, one or a plurality of sensors 114 can be provided, which can in each case have a plurality of sensor regions 116, for example in a matrix arrangement. This is merely indicated schematically in figure 14. For each of said sensor regions 116, by way of example, an evaluation method in accordance with the above description can be carried out, for example in order to generate at least one item of geometrical information, in particular at least one item of location information, about the at least one object 112 or a partial region of the object 112, for example that partial region from which the electromagnetic radiation 134 that impinges on the respective sensor region 116 originates. In order to ensure the spatial resolution, the optional transfer device 130 can have for example a plurality of lenses 132. By way of example, the transfer device 130, as illustrated in figure 14, can have at least one lens array in order, for example, in a targeted manner, to assign lateral regions of a layer of the sample 212 in each case to a sensor region 116 of an optical sensor 114. In this way, a lateral spatial resolution in the x, y direction parallel to the layers 212 can simultaneously be effected by evaluation of the sensor signals of the individual sensor regions 116 of the sensor array, and depth information can be effected by evaluation of the optical sensors 114 arranged one behind another. In this case, a three-dimensional region of the sample 198 can be imaged simultaneously.

Human-machine interface and entertainment device

Figure 15 shows an exemplary embodiment of a human-machine interface 214 according to the invention, which can simultaneously also be embodied as an exemplary embodiment of an entertainment device 216 or can be a constituent part of such an entertainment device 216.

By way of example, at least one detector 110 according to the present invention can once again be provided, for example in accordance with one or more of the embodiments described above, with one or a plurality of optical sensors 114. Further elements of the detector 110 can be provided, which are not illustrated in figure 15, such as, for example, elements of an optional transfer device 130. Furthermore, one or a plurality of illumination sources 142 can be provided. Generally, with regard to possible embodiments of the detector 110, reference can be made for example to the description above.

The human-machine interface 214 can be designed to make it possible to exchange at least one item of information between a user 218 of a machine 220, which is merely indicated in figure 15, and the machine 220, for example to exchange control commands. The machine 220 can comprise, in principle, any desired device having at least one

function which can be controlled and/or influenced in some way. At least one optional evaluation device 122 of the at least one detector 110 or a part thereof can, as indicated in figure 15, be wholly or partly integrated into said machine 220, but can, in principle, also be formed separately from the machine 220.

5

The human-machine interface can be designed for example to generate, by means of the detector 112, at least one item of geometrical information, in particular at least one item of location information, of the user and to assign to the geometrical information at least one item of information, in particular at least one control command. For this purpose, by way of example, by means of the detector 110, a movement and/or a change in posture of the user 218 can be identified, for example, as indicated in figure 15, a hand movement and/or a specific hand posture. If, by way of example, such a hand movement and/or hand posture of a specific type is identified, for example by evaluation of one or a plurality of items of geometrical information, in particular items of location information, of the user 218, then it is possible to recognize, for example by comparison with a corresponding command list, that the user 218 would like to effect a specific input, for example would like to give the machine 220 a control command. As an alternative or in addition to direct geometrical information about the actual user 218, it is also possible, for example, to generate at least one item of geometrical information about a garment of the user 218 and/or an article moved by the user 218.

The machine 220 can furthermore comprise one or a plurality of further human-machine interfaces, which need not necessarily be embodied according to the invention, for example, as indicated in figure 15, at least one display 222 and/or at least one keyboard 224. The machine 220 can be, in principle, any desired type of machine or combination of machines.

In the context of an entertainment device 216, said machine 220 can be designed for example to carry out at least one entertainment function, for example at least one game, in particular with at least one graphical display on the display 222 and optionally a corresponding audio output. The user 218 can input at least one item of information for example via the human-machine interface, wherein the entertainment device is designed to alter the entertainment function in accordance with the information. By way of example, specific movements of virtual articles, for example of virtual persons in a game and/or movements of virtual vehicles in a game, can be controlled by means of corresponding movements of the user 218, which are in turn recognized by the detector 110. Other types of control of at least one entertainment function by the user 218 by means of the at least one detector 110 are also possible.

40 Security device

Figure 16 shows an exemplary embodiment of a security device 226 according to the invention. Said security device 226 can be integrated for example into a memory device 228 having at least one optical data storage device 230. The security device 226 once again comprises at least one detector 110, for example of the type described above. The detector 110 once again comprises at least one optical sensor 114 and optionally at least one transfer device 130, for example at least one lens 132, for example in the form of a printed lens and/or a printed lens array. As explained above, however, the detector 110 of the security device 226 can also be embodied without a transfer device 130. Furthermore, the detector 110 once again comprises at least one evaluation device 122 for evaluating signals of the optical sensor 114.

The security device 226 is designed to carry out at least one security application. In particular, it can be designed to identify and/or avoid access to data of the optical data storage device 230. In general, one or a plurality of reading beams 232 are used for reading out the data of the optical data storage device 230. By way of example, this can involve focused reading beams in order to read individual information modules of the optical data storage device 230, the lateral resolution of which is typically in the range of a few hundred nanometers to a few tens or a few hundreds of micrometers. The security device 226 can be arranged so close to the optical data storage device 230 and/or be completely or partly integrated into the optical data storage device 230 such that the reading beam 232 or the reading beams 232 also impinge on the security device 226.

In contrast to impingement of diffuse light on the optical sensor 114 and the sensor region 116 thereof, which would lead to a comparatively low sensor signal, the impingement of focused light, for example of a focused reading beam 232, in particular of a focused laser beam, generally leads to a strongly boosted sensor signal, which can be identified by the evaluation device 122. This effect generally occurs - on account of the above-described geometry dependence of the sensor signal - even when the reading beam 232 has a very weak total power which does not exceed a total power of ambient light impinging on the sensor region 116.

Accordingly, the evaluation device 122 and/or other components of the memory device 228 or some other device which comprises the security device 226 can implement corresponding measures if a reading beam 232 is identified. In particular, the evaluation device 122 can output, via at least one interface 234, at least one warning signal which indicates, for example, that an attempt at reading by means of focused reading beams 232 has been effected. In accordance with this identification and the warning signal, a memory bit can be altered, for example, which indicates that the optical data storage device 230 has already been read once. Alternatively or additionally, other measures can be implemented, for example outputting of a corresponding warning to a user and/or

administrator and/or destruction of the optical data storage device 230, such that an optical data storage device 230 that can only be read once can be generated.

5 The security device 226 described can be integrated into various types of devices. Thus, it is possible, for example, to equip optical data storage devices 230 in the form of optical ROMs according to the invention. Optical data storage devices 230 in the form, for example, of holographic data storage devices and/or in the form of bar codes can also be embodied accordingly. In this way, it is possible for example to ensure, for example by the destruction of the optical data storage device 230 after the latter has been read once,
10 that the optical data storage device 230 and/or the memory device 228, for example an entry card and/or a ticket, can only be used once. Various other embodiments of the security device are conceivable.

Synthesis examples:

Syntheses of various compounds which can be used in dye solar cells 154 in the context of the present invention, in particular as p-type semiconductors 166, are listed by way of example hereinafter. Possible syntheses of compounds of the formula (I) are described, for example:

(A) General synthesis schemes for preparation of compounds of the formula I:

10 (a) *Synthesis route I:*

(a1) *Synthesis step I-R1:*

15

The synthesis in synthesis step I-R1 was based on the references cited below:

c) Li, Zhong Hui; Wong, Man Shing; Tao, Ye; D'Iorio, Marie; J. Org. Chem.; EN; 69; 3; 2004; 921 - 927.

(a3) *Synthesis step I-R3:*

5

The synthesis in synthesis step I-R3 was based on the reference cited below:

10

J. Grazulevicius; J. of Photochem. and Photobio., A: Chemistry 2004 162(2-3), 249-252.

The compounds of the formula I can be prepared via the sequence of synthesis steps shown above in synthesis route I. In steps (I-R1) to (I-R3), the reactants can be coupled, for example, by Ullmann reaction with copper as a catalyst or under palladium catalysis.

5 (b) *Synthesis route II:*

(b1) *Synthesis step II-R1:*

10 The synthesis in synthesis step II-R1 was based on the references cited under I-R2.

(b2) *Synthesis step II-R2:*

5 The synthesis in synthesis step II-R2 was based on the references cited below:

a) Bacher, Erwin; Bayerl, Michael; Rudati, Paula; Reckefuss, Nina; Müller, C. David; Meerholz, Klaus; Nuyken, Oskar; *Macromolecules*; 38; 5; 2005; 1640 – 1647,

10 b) Goodson, Felix E.; Hauck, Sheila; Hartwig, John F.; *J. Am. Chem. Soc.*; 121; 33; 1999; 7527 – 7539; Hauck, Sheila I.; Lakshmi, K. V.; Hartwig, John F.; *Org. Lett.*; 1; 13; 1999; 2057 – 2060.

(b3) *Synthesis step II-R3:*

5

The compounds of the formula I can be prepared via the sequence of synthesis steps shown above in synthesis route II. In steps (II-R1) to (II-R3), the reactants can be coupled, as also in synthesis route I, for example, by Ullmann reaction with copper as a catalyst or under palladium catalysis.

(c) Preparation of the starting amines:

When the diarylamines in synthesis steps I-R2 and II-R1 of synthesis routes I and II are not commercially available, they can be prepared, for example, by Ullmann reaction with
 5 copper as a catalyst or under palladium catalysis, according to the following reaction:

The synthesis was based on the review articles listed below:

10

Palladium-catalyzed C-N coupling reactions:

(B) Synthesis example 1: Synthesis of the compound ID367 (synthesis route I)

(B1): Synthesis step according to general synthesis scheme I-R1:

- 5 A mixture of 4,4'-dibromobiphenyl (93.6 g; 300 mmol), 4-methoxyaniline (133 g; 1.08 mol), Pd(dppf)Cl₂ (Pd(1,1'-bis(diphenylphosphino)ferrocene)Cl₂; 21.93 g; 30 mmol) and t-BuONa (sodium tert-butoxide; 109.06 g; 1.136 mol) in toluene (1500 ml) was stirred under a nitrogen atmosphere at 110°C for 24 hours. After cooling, the mixture was diluted with diethyl ether and filtered through a Celite® pad (from Carl Roth). The filter
10 bed was washed with 1500 ml each of ethyl acetate, methanol and methylene chloride. The product was obtained as a light brown solid (36 g; yield: 30%).

¹H NMR (400 MHz, DMSO): δ 7.81 (s, 2H), 7.34-7.32 (m, 4H), 6.99-6.97 (m, 4H), 6.90-6.88 (m, 4H), 6.81-6.79 (m, 4H), 3.64 (s, 6H).

15

(B2): Synthesis step according to general synthesis scheme I-R2:

- 20 Nitrogen was passed for a period of 10 minutes through a solution of dppf (1,1'-bis(diphenylphosphino)ferrocene; 0.19 g; 0.34 mmol) and Pd₂(dba)₃ (tris(dibenzylideneacetone)dipalladium(0); 0.15 g; 0.17 mmol) in toluene (220 ml). Subsequently, t-BuONa (2.8 g; 29 mmol) was added and the reaction mixture was stirred for a further 15 minutes. 4,4'-Dibromobiphenyl (25 g; 80 mmol) and 4,4'-
25 dimethoxydiphenylamine (5.52 g; 20 mmol) were then added successively. The reaction mixture was heated at a temperature of 100°C under a nitrogen atmosphere for 7 hours.

After cooling to room temperature, the reaction mixture was quenched with ice-water, and the precipitated solid was filtered off and dissolved in ethyl acetate. The organic layer was washed with water, dried over sodium sulfate and purified by column chromatography (eluent: 5% ethyl acetate/hexane). A pale yellow solid was obtained (7.58 g, yield: 82%).

^1H NMR (300 MHz, DMSO- d_6): 7.60-7.49 (m, 6H), 7.07-7.04 (m, 4H), 6.94-6.91 (m, 4H), 6.83-6.80 (d, 2H), 3.75 (s, 6H).

(B3): Synthesis step according to general synthesis scheme I-R3:

N⁴,N^{4'}-Bis(4-methoxyphenyl)biphenyl-4,4'-diamine (product from synthesis step I-R1; 0.4 g; 1.0 mmol) and product from synthesis step I-R2 (1.0 g; 2.2 mmol) were added under a nitrogen atmosphere to a solution of t-BuONa (0.32 g; 3.3 mmol) in o-xylene (25 ml). Subsequently, palladium acetate (0.03 g; 0.14 mmol) and a solution of 10% by weight of P(t-Bu)₃ (tris-t-butylphosphine) in hexane (0.3 ml; 0.1 mmol) were added to the reaction mixture which was stirred at 125°C for 7 hours. Thereafter, the reaction mixture was diluted with 150 ml of toluene and filtered through Celite®, and the organic layer was dried over Na₂SO₄. The solvent was removed and the crude product was reprecipitated three times from a mixture of tetrahydrofuran (THF)/methanol. The solid was purified by column chromatography (eluent: 20% ethyl acetate/hexane), followed by a precipitation with THF/methanol and an activated carbon purification. After removing the solvent, the product was obtained as a pale yellow solid (1.0 g, yield: 86%).

^1H NMR (400 MHz, DMSO- d_6): 7.52-7.40 (m, 8H), 6.88-7.10 (m, 32H), 6.79-6.81 (d, 4H), 3.75 (s, 6H), 3.73 (s, 12H).

(C) Synthesis example 2: Synthesis of the compound ID447 (synthesis route II)

5

(C1) Synthesis step according to general synthesis scheme II-R2:

- 10 p-Anisidine (5.7 g, 46.1 mmol), t-BuONa (5.5 g, 57.7 mol) and P(t-Bu)₃ (0.62 ml, 0.31 mmol) were added to a solution of the product from synthesis step I-R2 (17.7 g, 38.4 mmol) in toluene (150 ml). After nitrogen had been passed through the reaction mixture for 20 minutes, Pd₂(dba)₃ (0.35 g, 0.38 mmol) was added. The resulting reaction mixture was left to stir under a nitrogen atmosphere at room temperature for 16 hours.
- 15 Subsequently, it was diluted with ethyl acetate and filtered through Celite®. The filtrate was washed twice with 150 ml each of water and saturated sodium chloride solution. After the organic phase had been dried over Na₂SO₄ and the solvent had been removed, a black solid was obtained. This solid was purified by column chromatography (eluent: 0–25% ethyl acetate/hexane). This afforded an orange solid (14 g, yield: 75%).

20

^1H NMR (300 MHz, DMSO): 7.91 (s, 1H), 7.43-7.40 (d, 4H), 7.08-6.81 (m, 16H), 3.74 (s, 6H), 3.72 (s, 3H).

(C1) Synthesis step according to general synthesis scheme II-R3:

- 5 t-BuONa (686 mg; 7.14 mmol) was heated at 100°C under reduced pressure, then the reaction flask was purged with nitrogen and allowed to cool to room temperature. 2,7-Dibromo-9,9-dimethylfluorene (420 mg; 1.19 mmol), toluene (40 ml) and Pd[P(^tBu)₃]₂ (20 mg; 0.0714 mmol) were then added, and the reaction mixture was stirred at room temperature for 15 minutes. Subsequently, N,N,N'-p-trimethoxytriphenylbenzidine (1.5 g; 1.27 mmol) was added to the reaction mixture which was stirred at 120°C for 5 hours.
- 10 The mixture was filtered through a Celite®/MgSO₄ mixture and washed with toluene. The crude product was purified twice by column chromatography (eluent: 30% ethyl acetate/hexane) and, after twice reprecipitating from THF/methanol, a pale yellow solid was obtained (200 mg, yield: 13%).

15

¹H NMR: (400 MHz, DMSO-d₆): 7.60-7.37 (m, 8H), 7.02-6.99 (m, 16H), 6.92-6.87 (m, 20H), 6.80-6.77 (d, 2H), 3.73 (s, 6H), 3.71 (s, 12H), 1.25 (s, 6H)

(D) Synthesis example 3: Synthesis of the compound ID453 (synthesis route I)*(D1) Preparation of the starting amine:*

5 Step 1:

NaOH (78 g; 4 eq) was added to a mixture of 2-bromo-9H-fluorene (120 g; 1 eq) and
10 BnEt_3NCl (benzyltriethylammonium chloride; 5.9 g; 0.06 eq) in 580 ml of DMSO (dimethylsulfoxide). The mixture was cooled with ice-water, and methyl iodide (MeI) (160 g; 2.3 eq) was slowly added dropwise. The reaction mixture was left to stir overnight, then poured into water and subsequently extracted three times with ethyl acetate. The combined organic phases were washed with a saturated sodium chloride solution and
15 dried over Na_2SO_4 , and the solvent was removed. The crude product was purified by column chromatography using silica gel (eluent: petroleum ether). After washing with methanol, the product (2-bromo-9,9'-dimethyl-9H-fluorene) was obtained as a white solid (102 g).

20 ^1H NMR (400 MHz, CDCl_3): δ 1.46 (s, 6 H), 7.32 (m, 2 H), 7.43 (m, 2 H), 7.55 (m, 2 H), 7.68 (m, 1 H)

Step 2:

p-Anisidine (1.23 g; 10.0 mmol) and 2-bromo-9,9'-dimethyl-9H-fluorene (3.0 g; 11.0 mmol) were added under a nitrogen atmosphere to a solution of t-BuONa (1.44 g; 15.0 mmol) in 15 ml of toluene (15 ml). Pd₂(dba)₃ (92 mg; 0.1 mmol) and a 10% by weight solution of P(t-Bu)₃ in hexane (0.24 ml; 0.08 mmol) were added, and the reaction mixture was stirred at room temperature for 5 hours. Subsequently, the mixture was quenched with ice-water, and the precipitated solid was filtered off and dissolved in ethyl acetate. The organic phase was washed with water and dried over Na₂SO₄. After purifying the crude product by column chromatography (eluent: 10% ethyl acetate/hexane), a pale yellow solid was obtained (1.5 g, yield: 48%).

¹H NMR (300 MHz, C₆D₆): 7.59-7.55 (d, 1H), 7.53-7.50 (d, 1H), 7.27-7.22 (t, 2H), 7.19 (s, 1H), 6.99-6.95 (d, 2H), 6.84-6.77 (m, 4H), 4.99 (s, 1H), 3.35 (s, 3H), 1.37 (s, 6H).

(D2) Preparation of the compound ID453 for use in accordance with the invention

(D2.1): Synthesis step according to general synthesis scheme I-R2:

Product from a) (4.70 g; 10.0 mmol) and 4,4'-dibromobiphenyl (7.8 g; 25 mmol) were added to a solution of t-BuONa (1.15 g; 12 mmol) in 50 ml of toluene under nitrogen. Pd₂(dba)₃ (0.64 g; 0.7 mmol) and DPPF (0.78 g; 1.4 mmol) were added, and the reaction mixture was left to stir at 100°C for 7 hours. After the reaction mixture had been quenched with ice-water, the precipitated solid was filtered off and it was dissolved in ethyl acetate. The organic phase was washed with water and dried over Na₂SO₄. After purifying the crude product by column chromatography (eluent: 1% ethyl acetate/hexane), a pale yellow solid was obtained (4.5 g, yield: 82%).

¹H NMR (400 MHz, DMSO-d₆): 7.70-7.72 (d, 2H), 7.54-7.58 (m, 6H), 7.47-7.48 (d, 1H), 7.21-7.32 (m, 3H), 7.09-7.12 (m, 2H), 6.94-6.99 (m, 4H), 3.76 (s, 3H), 1.36 (s, 6H).

(D2.2) Synthesis step according to general synthesis scheme I-R3:

5

10 N⁴,N^{4'}-Bis(4-methoxyphenyl)biphenyl-4,4'-diamine (0.60 g; 1.5 mmol) and product from the preceding synthesis step I-R2 (1.89 g; 3.5 mmol) were added under nitrogen to a solution of t-BuONa (0.48 g; 5.0 mmol) in 30 ml of o-xylene. Palladium acetate (0.04 g; 0.18 mmol) and P(t-Bu)₃ in a 10% by weight solution in hexane (0.62 ml; 0.21 mmol) were added, and the reaction mixture was stirred at 125°C for 6 hours. Subsequently, the mixture was diluted with 100 ml of toluene and filtered through Celite®. The organic phase was dried over Na₂SO₄ and the resulting solid was purified by column chromatography (eluent: 10% ethyl acetate/hexane). This was followed by reprecipitation from THF/methanol to obtain a pale yellow solid (1.6 g, yield: 80%).

15

¹H NMR (400 MHz, DMSO-d₆): 7.67-7.70 (d, 4H), 7.46-7.53 (m, 14H), 7.21-7.31 (m, 4H), 7.17-7.18 (d, 2H), 7.06-7.11 (m, 8H), 6.91-7.01 (m, 22H), 3.75 (s, 12H), 1.35 (s, 12H).

(E) Further compounds of the formula I for use in accordance with the invention:

The compounds listed below were obtained analogously to the syntheses described above:

(E1) Synthesis example 4: Compound ID320

^1H NMR (300 MHz, THF- d_8): δ 7.43-7.46 (d, 4H), 7.18-7.23 (t, 4H), 7.00-7.08 (m, 16H), 6.81-6.96 (m, 18H), 3.74 (s, 12H)

(E2) Synthesis example 5: Compound ID321

^1H NMR (300 MHz, THF- d_8): δ 7.37-7.50 (t, 8H), 7.37-7.40 (d, 4H), 7.21-7.26 (d, 4H), 6.96-7.12 (m, 22H), 6.90-6.93 (d, 4H), 6.81-6.84 (d, 8H), 3.74 (s, 12H)

(E3) Synthesis example 6: Compound ID366

5

^1H NMR (400 MHz, DMSO- d_6): δ 7.60-7.70 (t, 4H), 7.40-7.55 (d, 2H), 7.17-7.29 (m, 8H), 7.07-7.09 (t, 4H), 7.06 (s, 2H), 6.86-7.00 (m, 24H), 3.73 (s, 6H), 1.31 (s, 12H)

(E4) Synthesis example 7: Compound ID368

10

^1H NMR (400 MHz, DMSO- d_6): δ 7.48-7.55 (m, 8H), 7.42-7.46 (d, 4H), 7.33-7.28 (d, 4H), 6.98-7.06 (m, 20H), 6.88-6.94 (m, 8H), 6.78-6.84 (d, 4H), 3.73 (s, 12H), 1.27 (s, 18H)

15

(E5) Synthesis example 8: Compound ID369

¹H NMR (400 MHz, THF-d₈): δ 7.60-7.70 (t, 4H), 7.57-7.54 (d, 4H), 7.48-7.51 (d, 4H),
 5 7.39-7.44 (t, 6H), 7.32-7.33 (d, 2H), 7.14-7.27 (m, 12H), 7.00-7.10 (m, 10H), 6.90-6.96
 (m, 4H), 6.80-6.87 (m, 8H), 3.75 (s, 12H), 1.42 (s, 12H)

(E6) Synthesis example 9: Compound ID446

¹H NMR (400 MHz, dms_o-d₆): δ 7.39-7.44 (m, 8H), 7.00-7.07 (m, 13H), 6.89-6.94 (m,
 10 19H), 6.79-6.81 (d, 4H), 3.73 (s, 18H)

(E7) Synthesis example 10: Compound ID450

- 5 ^1H NMR (400 MHz, $\text{dms}\text{-d}_6$): δ 7.55-7.57 (d, 2H), 7.39-7.45 (m, 8H), 6.99-7.04 (m, 15H), 6.85-6.93 (m, 19H), 6.78-6.80 (d, 4H), 3.72 (s, 18H), 1.68-1.71 (m, 6H), 1.07 (m, 6H), 0.98-0.99 (m, 8H), 0.58 (m, 6H)

(E8) Synthesis example 11: Compound ID452

10

- 15 ^1H NMR (400 MHz, DMSO-d_6): δ 7.38-7.44 (m, 8H), 7.16-7.19 (d, 4H), 6.99-7.03 (m, 12H), 6.85-6.92 (m, 20H), 6.77-6.79 (d, 4H), 3.74 (s, 18H), 2.00-2.25 (m, 4H), 1.25-1.50 (m, 6H)

(E9) Synthesis example 12: Compound ID480

- 5 ^1H NMR (400 MHz, DMSO- d_6): δ 7.40-7.42 (d, 4H), 7.02-7.05 (d, 4H), 6.96-6.99 (m, 28H), 6.74-6.77 (d, 4H), 3.73 (s, 6H), 3.71 (s, 12H)

(E10) Synthesis example 13: Compound ID518

- 10 ^1H NMR (400 MHz, DMSO- d_6): 7.46-7.51 (m, 8H), 7.10-7.12 (d, 2H), 7.05-7.08 (d, 4H), 6.97-7.00 (d, 8H), 6.86-6.95 (m, 20H), 6.69-6.72 (m, 2H), 3.74 (s, 6H), 3.72 (s, 12H), 1.24 (t, 12H)

15

(E11) Synthesis example 14: Compound ID519

¹H NMR (400 MHz, DMSO-d₆): 7.44-7.53 (m, 12H), 6.84-7.11 (m, 32H), 6.74-6.77 (d, 2H), 3.76 (s, 6H), 3.74 (s, 6H), 2.17 (s, 6H), 2.13 (s, 6H)

(E12) Synthesis example 15: Compound ID521

¹H NMR (400 MHz, THF-d₆): 7.36-7.42 (m, 12H), 6.99-7.07 (m, 20H), 6.90-6.92 (d, 4H), 6.81-6.84 (m, 8H), 6.66-6.69 (d, 4H), 3.74 (s, 12H), 3.36-3.38 (q, 8H), 1.41-1.17 (t, 12H)

(E13) Synthesis example 16: Compound ID522

¹H NMR (400 MHz, DMSO-d₆): 7.65 (s, 2H), 7.52-7.56 (t, 2H), 7.44-7.47 (t, 1H), 7.37-7.39 (d, 2H), 7.20-7.22 (m, 10H), 7.05-7.08 (dd, 2H), 6.86-6.94 (m, 8H), 6.79-6.80-6.86 (m, 12H), 6.68-6.73, (dd, 8H), 6.60-6.62 (d, 4H), 3.68 (s, 12H), 3.62 (s, 6H)

(E14) Synthesis example 17: Compound ID523

¹H NMR (400 MHz, THF-d₈): 7.54-7.56 (d, 2H), 7.35-7.40 (dd, 8H), 7.18 (s, 2H), 7.00-7.08 (m, 18H), 6.90-6.92 (d, 4H), 6.81-6.86 (m, 12H), 3.75 (s, 6H), 3.74 (s, 12H), 3.69 (s, 2H)

(E15) Synthesis example 18: Compound ID565

¹H NMR (400 MHz, THF-d₈): 7.97-8.00 (d, 2H), 7.86-7.89 (d, 2H), 7.73-7.76 (d, 2H),
 5 7.28-7.47 (m, 20H), 7.03-7.08 (m, 16H), 6.78-6.90 (m, 12H), 3.93-3.99 (q, 4H), 3.77 (s, 6H), 1.32-1.36 (s, 6H)

(E16) Synthesis example 19: Compound ID568

¹H NMR (400 MHz, DMSO-d₆): 7.41-7.51 (m, 12H), 6.78-7.06 (m, 36H), 3.82-3.84 (d, 4H), 3.79 (s, 12H), 1.60-1.80 (m, 2H), 0.60-1.60 (m, 28H)

15 *(E17) Synthesis example 20: Compound ID569*

¹H NMR (400 MHz, DMSO-d₆): 7.40-7.70 (m, 10H), 6.80-7.20 (m, 36H), 3.92-3.93 (d, 4H), 2.81 (s, 12H), 0.60-1.90 (m, 56H)

(E18) Synthesis example 21: Compound ID572

10

¹H NMR (400 MHz, THF-d₈): 7.39-7.47 (m, 12H), 7.03-7.11 (m, 20H), 6.39-6.99 (m, 8H), 6.83-6.90 (m, 8H), 3.78 (s, 6H), 3.76 (s, 6H), 2.27 (s, 6H)

(E19) Synthesis example 22: Compound ID573

15

90

^1H NMR (400 MHz, THF- d_8): 7.43-7.51 (m, 20H), 7.05-7.12 (m, 24H), 6.87-6.95 (m, 12H), 3.79 (s, 6H), 3.78 (s, 12H)

5

(E20) Synthesis example 23: Compound ID575

10 ^1H NMR (400 MHz, DMSO- d_6): 7.35-7.55 (m, 8H), 7.15-7.45 (m, 4H), 6.85-7.10 (m, 26H), 6.75-6.85 (d, 4H), 6.50-6.60 (d, 2H), 3.76 (s, 6H), 3.74 (s, 12H)

(E21) Synthesis example 24: Compound ID629

- 5 ^1H NMR (400 MHz, THF- d_8): 7.50-7.56 (dd, 8H), 7.38-7.41 (dd, 4H), 7.12-7.16 (d, 8H), 7.02-7.04 (dd, 8H), 6.91- 6.93 (d, 4H), 6.82-6.84 (dd, 8H), 6.65-6.68 (d, 4H) 3.87 (s, 6H), 3.74 (s, 12H)

(E22) Synthesis example 25: Compound ID631

10

^1H NMR (400 MHz, THF- d_6): 7.52 (d, 2H), 7.43-7.47 (dd, 2H), 7.34-7.38 (m, 8H), 7.12-7.14 (d, 2H), 6.99-7.03 (m, 12H), 6.81-6.92 (m, 20H), 3.74 (s, 18H), 2.10 (s, 6H)

15

(F) Synthesis of compounds of the formula IV:

5

(a) Coupling of *p*-anisidine and 2-bromo-9,9-dimethyl-9H-fluorene

- 10 To 0.24 ml (0.08 mmol) of $P(t-Bu)_3$ ($d = 0.68$ g/ml) and 0.1 g of $Pd_2(dba)_2$ [=tris(dibenzylideneacetone)dipalladium(0)] (0.1 mmol) were added 10 ml to 15 ml of toluene (anhydrous, 99.8%), and the mixture was stirred at room temperature for 10 min. 1.44 g (15 mmol) of sodium tert-butoxide (97.0%) were added and the mixture was stirred at room temperature for a further 15 min. Subsequently, 2.73 g (11 mmol) of 2-bromo-9,9-dimethyl-9H-fluorene were added and the reaction mixture was stirred for a further 15 min. Finally, 1.23 g (10 mmol) of *p*-anisidine were added and the mixture was stirred at 90°C for 4 h.

20 The reaction mixture was admixed with water and the product was precipitated from hexane. The aqueous phase was additionally extracted with ethyl acetate. The organic phase and the precipitated solid which had been filtered off were combined and purified by column chromatography on an SiO_2 phase (10:1 hexane:ethyl acetate).

1.5 g (yield: 47.6%) of a yellow solid were obtained.

^1H NMR (300 MHz, C_6D_6): 6.7-7.6 (m, 11H), 5.00 (s, 1H), 3.35 (s, 3H), 1.37 (s, 6H)

5

(b) Coupling of the product from (a) with tris(4-bromophenyl)amine

- 10 To 0.2 ml (0.07 mmol) of $\text{P}(\text{t-Bu})_3$ ($D = 0.68$ g/ml) and 0.02 g (0.1 mmol) of palladium acetate were added 25 ml of toluene (anhydrous), and the mixture was stirred at room temperature for 10 min. 0.4 g (1.2 mmol) of sodium tert-butoxide (97.0%) was added and the mixture was stirred at room temperature for a further 15 min. Subsequently, 0.63 g (1.3 mmol) of tris(4-bromophenyl)amine was added and the reaction mixture was stirred
- 15 for a further 15 min. Finally, 1.3 g (1.4 mmol) of the product from step (a) were added and the mixture was stirred at 90°C for 5 h.

- The reaction mixture was admixed with ice-cold water and extracted with ethyl acetate. The product was precipitated from a mixture of hexane/ethyl acetate and purified by
- 20 column chromatography on SiO_2 phase (9:1 → 5:1 hexane:ethyl acetate gradient).

0.7 g (yield: 45%) of a yellow product was obtained.

^1H NMR (300 MHz, C_6D_6): 6.6-7.6 (m, 45H), 3.28 (s, 9H), 1.26 (s, 18H)

25

(G) Synthesis of compounds ID504:

- 5 The preparation proceeded from (4-bromophenyl)bis(9,9-dimethyl-9H-fluoren-2-yl) (see Chemical Communications, 2004, 68-69), which was first reacted with 4,4,5,5,4',4',5',5'-octamethyl-[2,2']bi[[1,3,2]dioxaborolanyl] (step a). This was followed by coupling with 9Br-DIPP-PDCI (step b). This was followed by hydrolysis to give the anhydride (step c) and subsequent reaction with glycine to give the final compound (step d).

10

Step a:

- A mixture of 30 g (54 mmol) of (4-bromophenyl)bis(9,9-dimethyl-9H-fluoren-2-yl), 41 g (162 mmol) of 4,4,5,5,4',4',5',5'-octamethyl-[2,2']bi[[1,3,2]dioxaborolanyl], 1 g (1.4 mmol) of Pd(dppf)₂Cl₂, 15.9 g (162 mmol) of potassium acetate and 300 ml of dioxane was heated to 80°C and stirred for 36 h.

15

After cooling, the solvent was removed and the residue was dried at 50°C in a vacuum drying cabinet.

20

- Purification was effected by filtration through silica gel with the eluent 1:1 n-hexane:dichloromethane. After the removal of the reactant, the eluent was switched to dichloromethane. The product was isolated as a reddish and tacky residue. This was extracted by stirring with methanol at RT for 0.5 h. The light-colored precipitate was filtered off. After drying at 45°C in a vacuum drying cabinet, 24 g of a light-colored solid were obtained, which corresponds to a yield of 74%.

25

Analytical data

^1H NMR (500MHz, CD_2Cl_2 , 25°C): δ = 7.66-7.61 (m, 6H); 7.41-7.4 (m, 2H); 7.33-7.25 (m, 6H); 7.13-7.12 (m, 2H); 7.09-7.07 (m, 2H); 1.40 (s, 12H); 1.32 (s, 12H)

Step b:

17.8 g (32 mmol) of 9Br-DIPP-PDCl and 19 ml (95 mmol) of 5 molar NaOH were introduced into 500 ml of dioxane. This mixture was degassed with argon for 30 min. Then 570 mg (1.1 mmol) of $\text{Pd}[\text{P}(\text{tBu})_3]_2$ and 23 g (38 mmol) of stage a were added and the mixture was stirred at 85°C under argon for 17 h.

Purification was effected by column chromatography with the eluent 4:1 dichloromethane:toluene.

22.4 g of a violet solid were obtained, which corresponds to a yield of 74%.

Analytical data:

^1H NMR (500MHz, CH_2Cl_2 , 25°C): δ = 8.59-8.56 (m, 2H); 8.46-8.38 (m, 4H); 8.21-8.19 (d, 1H); 7.69-7.60 (m, 6H); 7.52-7.25 (m, 17H); 2.79-2.77 (m, 2H); 1.44 (s, 12H); 1.17-1.15 (d, 12H)

Step c:

22.4 g (23 mmol) of step b and 73 g (1.3 mol) of KOH were introduced into 200 ml of 2-methyl-2-butanol and the mixture was stirred at reflux for 17 h.

After cooling, the reaction mixture was added to 1 l of ice-water + 50 ml of concentrated acetic acid. The orange-brown solid was filtered through a frit and washed with water.

The solid was dissolved in dichloromethane and extracted with demineralized water. 10 ml of concentrated acetic acid were added to the organic phase, which was stirred at RT. The solvent was removed from the solution. The residue was extracted by stirring with methanol at RT for 30 min, filtered with suction through a frit and dried at 55°C in a vacuum drying cabinet.

This afforded 17.5 g of a violet solid, which corresponds to a yield of 94%. The product was used unpurified in the next step.

Step d:

17.5 g (22 mmol) of stage c, 16.4 g (220 mmol) of glycine and 4 g (22 mmol) of zinc acetate were introduced into 350 ml of N-methylpyrrolidone and the mixture was stirred at 130°C for 12 h.

- 5 After cooling, the reaction mixture was added to 1 l of demineralized water. The precipitate was filtered through a frit, washed with water and dried at 70°C in a vacuum drying cabinet.

- 10 Purification was effected by means of column chromatography with the eluent 3:1 dichloromethane:ethanol + 2% triethylamine. The isolated product was extracted by stirring at 60°C with 50% acetic acid. The solid was filtered off with suction through a frit, washed with water and dried at 80°C in a vacuum drying cabinet.

7.9 g of a violet solid were obtained, which corresponds to a yield of 42%.

15

Analytical data:

- 20 ¹H NMR (500MHz, THF, 25°C): δ = 8.37-8.34 (m, 2H); 8.25-8.18 (m, 4H); 8.12-8.10 (d, 1H); 7.74-7.70 (m, 4H); 7.59-7.53 (m, 4H); 7.45-7.43 (m, 4H); 7.39-7.37 (m, 2H); 7.32-7.22 (m, 6H); 4.82 (s, 2H); 1.46 (s, 12H)

(H) Synthesis of compounds ID662:

ID662

25

ID662 was prepared by reacting the corresponding commercially available hydroxamic acid [2-(4-butoxyphenyl)-N-hydroxyacetamide] with sodium hydroxide.

Patent claims

1. A detector (110) for optically detecting at least one object (112), comprising at least one optical sensor (114), wherein the optical sensor (114) has at least one sensor region (116), in particular at least one sensor region (116) comprising at least one sensor area (118), wherein the optical sensor (114) is designed to generate at least one sensor signal in a manner dependent on an illumination of the sensor region (116), wherein the sensor signal, given the same total power of the illumination is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area (118), wherein the detector (110) furthermore has at least one evaluation device (122), wherein the evaluation device (122) is designed to generate at least one item of geometrical information from the sensor signal, in particular at least one item of geometrical information about the illumination and/or the object (112).
2. The detector (110) according to the preceding claim, wherein the detector (110) furthermore has at least one modulation device (138) for modulating the illumination.
3. The detector (110) according to the preceding claim, wherein the detector (110) is designed to detect at least two sensor signals in the case of different modulations, in particular at least two sensor signals at respectively different modulation frequencies, wherein the evaluation device (122) is designed to generate the geometrical information from the at least two sensor signals.
4. The detector (110) according to any of the preceding claims, wherein the optical sensor (114) is furthermore designed in such a way that the sensor signal, given the same total power of the illumination, is dependent on a modulation frequency of a modulation of the illumination.
5. The detector (110) according to any of the preceding claims, wherein the sensor region (116) is exactly one continuous sensor region (116), wherein the sensor signal is a uniform sensor signal for the entire sensor region (116).
6. The detector (110) according to any of the preceding claims, wherein the sensor signal is selected from the group consisting of a photocurrent and a photovoltage.
7. The detector (110) according to any of the preceding claims, wherein the optical sensor (114) comprises at least one semiconductor detector (148), in particular an organic semiconductor detector (150) comprising at least one organic material,

preferably an organic solar cell (152) and particularly preferably a dye solar cell (154), in particular a solid dye solar cell.

- 5 8. The detector (110) according to the preceding claim, wherein the optical sensor (114) comprises at least one first electrode (158), at least one n-semiconducting metal oxide (162), at least one dye (164), at least one p-semiconducting organic material (166), preferably a solid p-semiconducting organic material, and at least one second electrode (168).
- 10 9. The detector (110) according to any of the preceding claims, wherein the geometrical information comprises at least one item of location information of the object (112).
- 15 10. The detector (110) according to the preceding claim, wherein the evaluation device (122) is designed to determine the geometrical information from at least one predefined relationship between the geometry of the illumination and a relative positioning of the object (112) with respect to the detector (110), preferably taking account of a known power of the illumination and optionally taking account of a modulation frequency with which the illumination is modulated.
- 20 11. The detector (110) according to any of the preceding claims, furthermore comprising at least one transfer device (130), wherein the transfer device (130) is designed to feed electromagnetic radiation (134) emerging from the object (112) to the optical sensor (114) and thereby to illuminate the sensor region (116).
- 25 12. The detector (110) according to any of the preceding claims, furthermore comprising at least one illumination source (142).
- 30 13. The detector (110) according to the preceding claim, wherein the illumination source (142) is selected from: an illumination source (142), which is at least partly connected to the object (112) and/or is at least partly identical to the object (112); an illumination source (142) which is designed to at least partly illuminate the object (112) with a primary radiation (144).
- 35 14. A distance measuring device (180), in particular for use in a motor vehicle, comprising at least one detector (110) according to any of the preceding claims, wherein the detector (110) is designed to determine at least one item of geometrical information of at least one object (112), wherein the geometrical information comprises at least one item of location information of the object (112),
40 in particular a distance between a motor vehicle and at least one object (112) and preferably a distance between the motor vehicle and at least one object (112)

selected from the group consisting of a further motor vehicle, an obstacle, a cyclist and a pedestrian.

- 5 15. An imaging device (196) for imaging at least one sample (198), wherein the imaging device (196) comprises at least one detector (110) according to any of the preceding claims relating to a detector (110), wherein the imaging device (196) is designed to image a plurality of partial regions of the sample (198) onto the sensor region (116) and to thereby generate sensor signals assigned to the partial regions, wherein the imaging device (196) is designed to generate items of geometrical information of the respective partial regions from the sensor signals, wherein the items of geometrical information comprise items of location information.
- 10
- 15 16. A human-machine interface (214) for exchanging at least one item of information between a user (218) and a machine (220), in particular for inputting control commands, wherein the human-machine interface (214) comprises at least one detector (110) according to any of the preceding claims relating to a detector (110), wherein the human-machine interface (214) is designed to generate at least one item of geometrical information of the user (218) by means of the detector (110), wherein the human-machine interface (214) is designed to assign to the geometrical information at least one item of information, in particular at least one control command.
- 20
- 25 17. An entertainment device (216) for carrying out at least one entertainment function, in particular a game, wherein the entertainment device (216) comprises at least one human-machine interface (214) according to the preceding claim, wherein the entertainment device (216) is designed to enable at least one item of information to be input by a player (218) by means of the human-machine interface (214), wherein the entertainment device (216) is designed to vary the entertainment function in accordance with the information.
- 30
- 35 18. A security device (226) for carrying out at least one security application in particular for identifying and/or avoiding an access to data of an optical data storage device, wherein the security device (226) comprises at least one detector (110) according to any of the preceding claims relating to a detector (110), wherein the security device (226) is designed to identify, by means of the detector (110), impingement of focused electromagnetic radiation (134), in particular laser beams, on the security device (226) and preferably to generate at least one warning signal.

19. A method for optically detecting at least one object (112), in particular using a detector (110) according to any of the preceding claims relating to a detector (110), wherein at least one optical sensor (114) is used, wherein the optical sensor (114) has at least one sensor region (116), wherein electromagnetic radiation (134) emerging from the object is fed to the optical sensor (114) and thereby the sensor region (116) is illuminated, wherein the optical sensor (114) generates at least one sensor signal in a manner dependent on the illumination of the sensor region (116), wherein the sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination.
20. The method according to the preceding claim, wherein at least one item of geometrical information of the object (112) is generated from the sensor signal, in particular at least one item of location information of the object (112).
21. Use of a detector (110) according to any of the preceding claims relating to a detector (110) for a purpose of use, selected from the group consisting of: distance measurement, in particular in traffic technology; imaging, in particular in microscopy; an entertainment application; a security application; a human-machine interface application.
22. Use of an organic solar cell (152), in particular a dye solar cell (154), preferably a solid dye solar cell, as optical sensor (114), wherein at least one sensor signal is generated in the use, wherein the sensor signal, given the same total power of an illumination is dependent on a geometry of the illumination on the organic solar cell, wherein at least one item of geometrical information of at least one object (112) is generated from the sensor signal in the use.

Detector for optically detecting at least one object

Description

5 Field of the invention

The present invention is based on previous European patent application number 13171901.5, the full content of which is herewith included by reference. The invention relates to a detector, a detector system and a method for determining a position of at least one object. The invention
10 further relates to a human-machine interface for exchanging at least one item of information between a user and a machine, an entertainment device, a tracking system, a camera and various uses of the detector device. The devices, systems, methods and uses according to the present invention specifically may be employed for example in various areas of daily life, gaming, traffic technology, production technology, security technology, photography such as
15 digital photography or video photography for arts, documentation or technical purposes, medical technology or in the sciences. However, other applications are also possible.

Prior art

20 A large number of optical sensors and photovoltaic devices are known from the prior art. While photovoltaic devices are generally used to convert electromagnetic radiation, for example, ultraviolet, visible or infrared light, into electrical signals or electrical energy, optical detectors are generally used for picking up image information and/or for detecting at least one optical parameter, for example, a brightness.

25 A large number of optical sensors which can be based generally on the use of inorganic and/or organic sensor materials are known from the prior art. Examples of such sensors are disclosed in US 2007/0176165 A1, US 6,995,445 B2, DE 2501124 A1, DE 3225372 A1 or else in numerous other prior art documents. To an increasing extent, in particular for cost reasons and
30 for reasons of large-area processing, sensors comprising at least one organic sensor material are being used, as described for example in US 2007/0176165 A1. In particular, so-called dye solar cells are increasingly of importance here, which are described generally, for example in WO 2009/013282 A1.

35 A large number of detectors for detecting at least one object are known on the basis of such optical sensors. Such detectors can be embodied in diverse ways, depending on the respective purpose of use. Examples of such detectors are imaging devices, for example, cameras and/or microscopes. High-resolution confocal microscopes are known, for example, which can be used in particular in the field of medical technology and biology in order to examine biological
40 samples with high optical resolution. Further examples of detectors for optically detecting at least one object are distance measuring devices based, for example, on propagation time methods of corresponding optical signals, for example laser pulses. Further examples of detectors for optically detecting objects are triangulation systems, by means of which distance measurements can likewise be carried out.

In US 2007/0080925 A1, a low power consumption display device is disclosed. Therein, photoactive layers are utilized that both respond to electrical energy to allow a display device to display information and that generate electrical energy in response to incident radiation. Display pixels of a single display device may be divided into displaying and generating pixels. The displaying pixels may display information and the generating pixels may generate electrical energy. The generated electrical energy may be used to provide power to drive an image.

In EP 1 667 246 A1, a sensor element capable of sensing more than one spectral band of electromagnetic radiation with the same spatial location is disclosed. The element consists of a stack of sub-elements each capable of sensing different spectral bands of electromagnetic radiation. The sub-elements each contain a non-silicon semiconductor where the non-silicon semiconductor in each sub-element is sensitive to and/or has been sensitized to be sensitive to different spectral bands of electromagnetic radiation.

In WO 2012/110924 A1, the content of which is herewith included by reference, a detector for optically detecting at least one object is proposed. The detector comprises at least one optical sensor. The optical sensor has at least one sensor region. The optical sensor is designed to generate at least one sensor signal in a manner dependent on an illumination of the sensor region. The sensor signal, given the same total power of the illumination, is dependent on a geometry of the illumination, in particular on a beam cross section of the illumination on the sensor area. The detector furthermore has at least one evaluation device. The evaluation device is designed to generate at least one item of geometrical information from the sensor signal, in particular at least one item of geometrical information about the illumination and/or the object.

US provisional applications 61/739,173, filed on December 19, 2012, 61/749,964, filed on January 8, 2013, and 61/867,169, filed on August 19, 2013, and international patent application PCT/IB2013/061095, filed on December 18, 2013, the full content of all of which is herewith included by reference, disclose a method and a detector for determining a position of at least one object, by using at least one transversal optical sensor and at least one optical sensor. Specifically, the use of sensor stacks is disclosed, in order to determine a longitudinal position of the object with a high degree of accuracy and without ambiguity.

Despite the advantages implied by the above-mentioned devices and detectors, specifically by the detectors disclosed in WO 2012/110924 A1, US 61/739,173 and 61/749,964, several technical challenges remain. Thus, generally, a need exists for detectors for detecting a position of an object in space which is both reliable and may be manufactured at low cost.

Problem addressed by the invention

It is therefore an object of the present invention to provide devices and methods facing the above-mentioned technical challenges of known devices and methods. Specifically, it is an object of the present invention to provide devices and methods which reliably may determine a

position of an object in space, preferably at a low technical effort and with low requirements in terms of technical resources and cost.

Summary of the invention

5

This problem is solved by the invention with the features of the independent patent claims. Advantageous developments of the invention, which can be realized individually or in combination, are presented in the dependent claims and/or in the following specification and detailed embodiments.

10

As used herein, the expressions "have", "comprise" and "contain" as well as grammatical variations thereof are used in a non-exclusive way. Thus, the expression "A has B" as well as the expression "A comprises B" or "A contains B" may both refer to the fact that, besides B, A contains one or more further components and/or constituents, and to the case in which, besides B, no other components, constituents or elements are present in A.

15

In a first aspect of the present invention, a detector for determining a position of at least one object is disclosed. As used herein, the term position refers to at least one item of information regarding a location and/or orientation of the object and/or at least one part of the object in space. Thus, the at least one item of information may imply at least one distance between at least one point of the object and the at least one detector. As will be outlined in further detail below, the distance may be a longitudinal coordinate or may contribute to determining a longitudinal coordinate of the point of the object. Additionally or alternatively, one or more other items of information regarding the location and/or orientation of the object and/or at least one part of the object may be determined. As an example, at least one transversal coordinate of the object and/or at least one part of the object may be determined. Thus, the position of the object may imply at least one longitudinal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one transversal coordinate of the object and/or at least one part of the object. Additionally or alternatively, the position of the object may imply at least one orientation information of the object, indicating an orientation of the object in space.

20

25

30

The detector comprises:

35

- at least one optical sensor, the optical sensor being adapted to detect a light beam traveling from the object towards the detector, the optical sensor having at least one matrix of pixels; and
- at least one evaluation device, the evaluation device being adapted to determine a number N of pixels of the optical sensor which are illuminated by the light beam, the evaluation device further being adapted to determine at least one longitudinal coordinate of the object by using the number N of pixels which are illuminated by the light beam.

40

As used herein, an optical sensor generally refers to a light-sensitive device for detecting a light beam, such as for detecting an illumination and/or a light spot generated by a light beam. The

optical sensor may be adapted, as outlined in further detail below, to determine at least one longitudinal coordinate of the object and/or of at least one part of the object, such as at least one part of the object from which the at least one light beam travels towards the detector.

5 As further used herein, a pixel generally refers to a light-sensitive element of the optical sensor, such as a minimum uniform unit of the optical sensor adapted to generate a light signal. As an example, each pixel may have a light-sensitive area of $1\ \mu\text{m}^2$ to $5\,000\,000\ \mu\text{m}^2$, preferably $100\ \mu\text{m}^2$ to $4\,000\,000\ \mu\text{m}^2$, preferably $1\,000\ \mu\text{m}^2$ to $1\,000\,000\ \mu\text{m}^2$ and more preferably $2\,500\ \mu\text{m}^2$ to $50\,000\ \mu\text{m}^2$. Still, other embodiments are feasible. The expression matrix generally refers to an
10 arrangement of a plurality of the pixels in space, which may be a linear arrangement or an areal arrangement. Thus, generally, the matrix preferably may be selected from the group consisting of a one-dimensional matrix and a two-dimensional matrix. As an example, the matrix may comprise 100 to $100\,000\,000$ pixels, preferably 1 000 to $1\,000\,000$ pixels and, more preferably, 10 000 to $500\,000$ pixels. Most preferably, the matrix is a rectangular matrix having pixels
15 arranged in rows and columns.

As further used herein, the term evaluation device generally refers to an arbitrary device adapted to perform the named operations, preferably by using at least one data processing device and, more preferably, by using at least one processor. Thus, as an example, the at least
20 one evaluation device may comprise at least one data processing device having a software code stored thereon comprising a number of computer commands.

The optical sensor may be adapted to generate at least one signal indicating an intensity of illumination for each of the pixels. Thus, as an example, the optical sensor may be adapted to
25 generate at least one electronic signal for each of the pixels, each signal indicating the intensity of illumination for the respective pixel. The signal may be an analogue and/or a digital signal. Further, the detector may comprise one or more signal processing devices, such as one or more filters and/or analogue-digital-converters for processing and/or preprocessing the at least one signal.

30 The evaluation device may be adapted to compare, for each of the pixels, the signal to at least one threshold in order to determine whether the pixel is an illuminated pixel or not. This at least one threshold may be an individual threshold for each of the pixels or may be a threshold which is a uniform threshold for the whole matrix. In case a plurality of optical sensors is provided, at
35 least one threshold may be provided for each of the optical sensors and/or for a group comprising at least two of the optical sensors, wherein, for two optical sensors, their respective thresholds may be identical or different. Thus, for each of the optical sensors, an individual threshold may be provided.

40 As will be outlined in further detail below, the threshold may be predetermined and/or fixed. Alternatively, the at least one threshold may be variable. Thus, the at least one threshold may be determined individually for each measurement or groups of measurements. Thus, at least one algorithm may be provided adapted to determine the threshold.

The evaluation device generally may be adapted to determine at least one pixel having the highest illumination out of the pixels by comparing the signals of the pixels. Thus, the detector generally may be adapted to determine one or more pixels and/or an area or region of the matrix having the highest intensity of the illumination by the light beam. As an example, in this way, a center of illumination by the light beam may be determined.

The highest illumination and/or the information about the at least one area or region of highest illumination may be used in various ways. Thus, as outlined above, the at least one above-mentioned threshold may be a variable threshold. As an example, the evaluation device may be adapted to choose the above-mentioned at least one threshold as a fraction of the signal of the at least one pixel having the highest illumination. Thus, the evaluation device may be adapted to choose the threshold by multiplying the signal of the at least one pixel having the highest illumination with a factor of $1/e^2$. As will be outlined in further detail below, this option is particularly preferred in case Gaussian propagation properties are assumed for the at least one light beam, since the threshold $1/e^2$ generally determines the borders of a light spot having a beam radius or beam waist w generated by a Gaussian light beam on the optical sensor.

The evaluation device may be adapted to determine the longitudinal coordinate of the object by using a predetermined relationship between the number N of the pixels which are illuminated by the light beam and the longitudinal coordinate of the object. Thus, generally, the diameter of the light beam, due to propagation properties generally known to the skilled person, changes with propagation, such as with a longitudinal coordinate of the propagation. The relationship between the number of illuminated pixels and the longitudinal coordinate of the object may be an empirically determined relationship and/or may be analytically determined. Thus, as an example, a calibration process may be used for determining the relationship between the number of illuminated pixels and the longitudinal coordinate. Additionally or alternatively, as mentioned above, the predetermined relationship may be based on the assumption of the light beam being a Gaussian light beam. The light beam may be a monochromatic light beam having a precisely one wavelength λ or may be a light beam having a plurality of wavelengths or a wavelength spectrum, wherein, as an example, a central wavelength of the spectrum and/or a wavelength of a characteristic peak of the spectrum may be chosen as the wavelength λ of the light beam. In case a plurality of optical sensors is used, specific predetermined relationships between the respective number of illuminated pixels of the optical sensors and the longitudinal coordinate may be used. Thus, as an example, for each optical sensor, a predetermined relationship between the number of illuminated pixels and the longitudinal coordinate may be provided. As will be outlined in further detail below, the optical sensors may be arranged in a stack. Further, the optical sensors may have different properties, such as different geometries such as different geometries of the matrix of pixels and/or of the pixels. Further, the optical sensors may have differing sensitivities, such as differing spectral sensitivities. By providing specific predetermined relationships between the respective numbers of illuminated pixels of the optical sensors, these differing properties of the optical sensors may be taken into account.

As an example of an analytically determined relationship, the predetermined relationship, which may be derived by assuming Gaussian properties of the light beam, may be:

$$N \sim \pi \cdot w_0^2 \cdot \left(1 + \left(\frac{z}{z_0}\right)^2\right), \quad (1)$$

5 wherein z is the longitudinal coordinate,
wherein w_0 is a minimum beam radius of the light beam when propagating in space,
wherein z_0 is a Rayleigh-length of the light beam with $z_0 = \pi \cdot w_0^2 / \lambda$, λ being the wavelength
of the light beam.

10 This relationship may generally be derived from the general equation of an intensity I of a
Gaussian light beam traveling along a z -axis of a coordinate system, with r being a coordinate
perpendicular to the z -axis and E being the electric field of the light beam:

$$I(r, z) = |E(r, z)|^2 = I_0 \cdot (w_0/w(z))^2 \cdot e^{-2r^2/w(z)^2} \quad (2)$$

15 The beam radius w of the transversal profile of the Gaussian light beam generally representing
a Gaussian curve is defined, for a specific z -value, as a specific distance from the z -axis at
which the amplitude E has dropped to a value of $1/e$ (approx. 36%) and at which the intensity I
has dropped to $1/e^2$. The minimum beam radius, which, in the Gaussian equation given above
(which may also occur at other z -values, such as when performing a z -coordinate
20 transformation), occurs at coordinate $z = 0$, is denoted by w_0 . Depending on the z -coordinate,
the beam radius generally follows the following equation when light beam propagates along the
 z -axis:

$$w(z) = w_0 \cdot \sqrt{1 + \left(\frac{z}{z_0}\right)^2} \quad (3)$$

25 With the number N of illuminated pixels being proportional to the illuminated area A of the
optical sensor:

$$N \sim A \quad (4)$$

or, in case a plurality of optical sensors $i = 1, \dots, n$ is used, with the number N_i of illuminated
30 pixels for each optical sensor being proportional to the illuminated area A_i of the respective
optical sensor

$$N_i \sim A_i \quad (4')$$

and the general area of a circle having a radius w :

$$A = \pi \cdot w^2, \quad (5)$$

the following relationship between the number of illuminated pixels and the z -coordinate may be derived:

$$N \sim \pi \cdot w_0^2 \cdot \left(1 + \left(\frac{z}{z_0}\right)^2\right) \quad (6)$$

5

or

$$N_i \sim \pi \cdot w_0^2 \cdot \left(1 + \left(\frac{z}{z_0}\right)^2\right), \quad (6')$$

respectively, with $z_0 = \pi \cdot w_0^2 / \lambda$, as mentioned above. Thus, with N or N_i , respectively, being
 10 the number of pixels within a circle being illuminated at an intensity $I \geq I_0/e^2$, as an example, N or N_i may be determined by simple counting of pixels and/or other methods, such as a histogram analysis. In other words, a well-defined relationship between the z -coordinate and the number of illuminated pixels N or N_i , respectively, may be used for determining the longitudinal coordinate z of the object and/or of at least one point of the object, such as at least
 15 one longitudinal coordinate of at least one beacon device being one of integrated into the object and/or attached to the object.

In the equations given above, such as in equation (1), it is assumed that the light beam has a focus at position $z = 0$. It shall be noted however, that a coordinate transformation of the z -
 20 coordinate is possible, such as by adding and/or subtracting a specific value. Thus, as an example, the position of the focus typically is dependent on the distance of the object from the detector and/or on other properties of the light beam. Thus, by determining the focus and/or the position of the focus, a position of the object, specifically a longitudinal coordinate of the object, may be determined, such as by using an empirical and/or an analytical relationship between a
 25 position of the focus and a longitudinal coordinate of the object and/or the beacon device. Further, imaging properties of the at least one optional transfer device, such as the at least one optional lens, may be taken into account. Thus, as an example, in case beam properties of the light beam being directed from the object towards the detector are known, such as in case emission properties of an illuminating device contained in a beacon device are known, by using
 30 appropriate Gaussian transfer matrices representing a propagation from the object to the transfer device, representing imaging of the transfer device and representing beam propagation from the transfer device to the at least one optical sensor, a correlation between a beam waist and a position of the object and/or the beacon device may easily be determined analytically. Additionally or alternatively, a correlation may empirically be determined by appropriate
 35 calibration measurements.

As outlined above, the matrix of pixels preferably may be a two-dimensional matrix. However, other embodiments are feasible, such as one-dimensional matrices. More preferably, as outlined above, the matrix of pixels is a rectangular matrix.

- 5 The detector may comprise precisely one optical sensor or may comprise a plurality of the optical sensors. In case a plurality of the optical sensors is provided, the optical sensors may arrange in various ways. Thus, as an example, the light beam may be split into two or more beams, each beam being directed towards one or more of the optical sensors. Additionally or alternatively, two or more of the optical sensors may be stacked along an axis, such as along an
10 optical axis of the detector, preferably with their sensitive areas face towards the same direction. Thus, as an example, the detector may comprise a plurality of the optical sensors, wherein the optical sensors are stacked along an optical axis of the detector.

- As an example, the detector may comprise n optical sensors, with $n > 1$. The evaluation device
15 generally may be adapted to determine the number N_i of the pixels which are illuminated by the light beam for each of the optical sensors, wherein $i \in \{1, n\}$ denotes the respective optical sensor. As used herein, "each" refers to the fact that a number of illuminated pixels is determined for each optical sensor part of a plurality of the optical sensors, notwithstanding the fact that optical sensors may exist which are not illuminated by the light beam and/or which are
20 used for other purposes, and, consequently, for which no number of illuminated pixels is determined.

- The evaluation device may be adapted to compare the number N_i of pixels which are illuminated by the light beam for each optical sensor with at least one neighboring optical
25 sensor, thereby resolving an ambiguity in the longitudinal coordinate of the object.

- The sensor signals of the optical sensors may be used in various ways. Thus, as an example, the redundancy of the sensor signals may be used for eliminating unknown information regarding the power of the light beam. Thus, the sensor signals may be normalized, such as by
30 setting the strongest sensor signal to value 1 or 100 and providing the remaining sensor signals as fractions of this strongest sensor signal. Thus, generally, the evaluation device may be adapted to normalize sensor signals of the optical sensors for a power of the light beam. Additionally or alternatively, however, as outlined above, a normalization may take place within each optical sensor, such as for setting appropriate thresholds for determining pixels which are
35 illuminated by the light beam and for determining pixels which are not illuminated by the light beam.

- The at least one optical sensor generally may be transparent or may be intransparent. Thus, as an example, the optical sensor may be transparent and adapted to transmit at least 10%,
40 preferably at least 20% and, more preferably, at least 50% of the power of the light beam. In case a plurality of the optical sensors is provided, such as in a stacked fashion, preferably, at least one of the optical sensors is transparent.

In case a plurality of the optical sensors is provided, which may be arranged in the stacked fashion and/or in another arrangement, the optical sensors may have identical spectral sensitivities or may provide different spectral sensitivities. Thus, as an example, at least two of the optical sensors may have a differing spectral sensitivity. As used herein, the term spectral sensitivity generally refers to the fact that the sensor signal of the optical sensor, for the same power of the light beam, may vary with the wavelength of the light beam. Thus, generally, at least two of the optical sensors may differ with regard to their spectral properties. This embodiment generally may be achieved by using different types of absorbing materials for the optical sensors, such as different types of dyes or other absorbing materials. Additionally or alternatively, differing spectral properties of the optical sensors may be generated by other means implemented into the optical sensors and/or into the detector, such as by using one or more wavelength-selective elements, such as one or more filters (such as color filters) in front of the optical sensors and/or by using one or more prisms and/or by using one or more dichroitic mirrors. Thus, in case a plurality of optical sensors is provided, at least one of the optical sensors may comprise a wavelength-selective element such as a color filter, having a specific transmission or reflection characteristic, thereby generating differing spectral properties of the optical sensors. Further, as will be outlined in further detail below, in case a plurality of optical sensors is used, these optical sensors may all be organic optical sensors, may all be inorganic optical sensors, may all be hybrid organic – inorganic optical sensors or may comprise an arbitrary combination of at least two optical sensors selected from the group consisting of organic optical sensors, inorganic optical sensors and hybrid organic – inorganic optical sensors.

In case a plurality of the optical sensors is used, wherein at least two of the optical sensors differ with regard to their respective spectral sensitivity, the evaluation device generally may be adapted to determine a color of the light beam by comparing sensor signals of the optical sensors having the differing spectral sensitivity. As used herein, the expression “determine a color” generally refers to the step of generating at least one item of spectral information about the light beam. The at least one item of spectral information may be selected from the group consisting of a wavelength, specifically a peak wavelength; color coordinates, such as CIE coordinates.

The determination of the color of the light beam may be performed in various ways which are generally known to the skilled person. Thus, the spectral sensitivities of the optical sensors may span a coordinate system in color space, and the signals provided by the optical sensors may provide a coordinate in this color space, as known to the skilled person for example from the way of determining CIE coordinates.

As an example, the detector may comprise two, three or more optical sensors in a stack. Thereof, at least two, preferably at least three, of the optical sensors may have differing spectral sensitivities. Further, the evaluation device may be adapted to generate at least one item of color information for the light beam by evaluating the signals of the optical sensors having differing spectral sensitivities.

As an example, at least three optical sensors being spectrally sensitive optical sensors may be contained in the stack. Thus, e.g., the spectrally sensitive optical sensors may comprise at least one red sensitive optical sensor, the red sensitive optical sensor having a maximum absorption wavelength λ_r in a spectral range $600 \text{ nm} < \lambda_r < 780 \text{ nm}$, wherein the spectrally sensitive optical sensors further comprise at least one green sensitive optical sensor, the green sensitive optical sensor having a maximum absorption wavelength λ_g in a spectral range $490 \text{ nm} < \lambda_g < 600 \text{ nm}$, wherein the spectrally sensitive optical sensors further may comprise at least one blue sensitive optical sensor, the blue sensitive optical sensor having a maximum absorption wavelength λ_b in a spectral range $380 \text{ nm} < \lambda_b < 490 \text{ nm}$. As an example, the red sensitive optical sensor, the green sensitive optical sensor and the blue sensitive optical sensor, in this order or in a different order, may be the first optical sensors of the optical sensor stack, facing towards the object.

The evaluation device may be adapted to generate at least two color coordinates, preferably at least three color coordinates, wherein each of the color coordinates is determined by dividing a signal of one of the spectrally sensitive optical sensors by a normalization value. As an example, the normalization value may contain a sum of the signals of all spectrally sensitive optical sensors. Additionally or alternatively, the normalization value may contain a detector signal of a white detector.

The at least one item of color information may contain the color coordinates. The at least one item of color information may, as an example, contain CIE coordinates.

In addition to the preferred at least two, more preferably at least three, spectrally sensitive optical sensors, the stack further may comprise at least one white detector, wherein the white detector may be adapted to absorb light in an absorption range of all spectrally sensitive detectors. Thus, as an example, the white detector may have an absorption spectrum absorbing light all over the visible spectral range.

The spectrally sensitive optical sensors each may comprise at least one dye, the dye being adapted to absorb light in one or more of the visible spectral range, the ultraviolet spectral range and the infrared spectral range, with a non-uniform absorption spectrum. As an example, the dyes each may have an absorption spectrum having at least one absorption peak. The absorption peak, as a solid, as a film or as sensitizer on a scaffold material (e.g. TiO_2), may have a width, such as a full width at half maximum (FWHM) which may be broad, such as by using dyes absorbing all over one or more of the visible, the infrared or the ultraviolet spectral range, or may be narrow, such as by using dyes having an FWHM of no more than 300 nm, preferably of no more than 200 nm, more preferably of no more than 80 nm, of no more than 60 nm or of no more than 40 nm. The absorption peaks of the dyes may be spaced apart by at least 60 nm, preferably at least 80 nm and, more preferably, by at least 100 nm. Other embodiments are feasible.

In case the detector comprises a plurality of optical sensors, as outlined above, the optical sensors preferably may be arranged in a stack. In case a plurality of optical sensors is provided,

the optical sensors may be identical, or at least two of the optical sensors may differ with regard to at least one property, such as with regard to a geometric property, a property of device setup or, as outlined above, spectral sensitivity.

5 As an example, as outlined above, the plurality of optical sensors may provide differing spectral sensitivities, such as an optical sensor with sensitivity in the red spectral range (R), an optical sensor with spectral sensitivity in the green spectral range (G) and an optical sensor with spectral sensitivity in the blue spectral range (B). As outlined above, the differing spectral sensitivities may be provided by various means, such as by providing absorbing materials
10 having differing spectral sensitivities and/or by providing one or more wavelength-selective elements. Thus, in a stack of optical sensors and/or in another arrangement of a plurality of optical sensors, various combinations of optical sensors having differing spectral sensitivities may be provided. As an example, an RGB stack may be provided, in the given order or in a different order.

15 Further, in case a plurality of optical sensors is provided, the plurality of optical sensors may differ with regard to device setup and/or with regard to the materials used in the optical sensors. Specifically, the optical sensors may differ with regard to their organic or inorganic in nature. Thus, the plurality of optical sensors and, more specifically, the stack, may comprise one or
20 more organic optical sensors, one or more inorganic optical sensors, one or more hybrid organic-inorganic optical sensors or an arbitrary combination of at least two of these optical sensors. Thus, as an example, the stack may consist of organic optical sensors only, may consist of inorganic optical sensors only or may consist of hybrid organic-inorganic optical sensors, only. Additionally or alternatively, the stack may comprise at least one organic optical
25 sensor and at least one inorganic optical sensor or may comprise at least one organic optical sensor and at least one hybrid organic-inorganic optical sensor or may comprise at least one organic optical sensor and at least one hybrid organic-inorganic optical sensor. Preferably, the stack may comprise at least one organic optical sensor and, further, preferably on a side of the stack furthest away from the object, at least one inorganic optical sensor. Thus, as an example,
30 as will be outlined in further detail below, the stack may comprise at least one organic optical sensor, such as at least one DSC or sDSC, and, further, at least one inorganic sensor such as a CCD or CMOS sensor chip more preferably on a side of the stack furthest away from the object.

Further, in case a plurality of optical sensors is provided, the optical sensors may differ with
35 regard to their transparency. Thus, as an example, all optical sensors may fully or partially be transparent. Alternatively, all optical sensors may fully or partially be intransparent (also referred to as opaque). Further, specifically in case the plurality of optical sensors is arranged as a stack, a combination of at least one at least partially transparent optical sensor and at least one at least partially intransparent optical sensor may be used. Thus, the stack may comprise one or
40 more transparent optical sensors and, additionally, preferably on a side of the stack furthest away from the object, at least one intransparent optical sensor. Thus, as outlined above, one or more at least partially transparent optical sensors may be provided by using one or more transparent organic optical sensors such as one or more transparent DSCs or sDSCs.

Additionally or alternatively, at least partially transparent optical sensors may be provided by using inorganic sensors, such as very thin inorganic optical sensors or inorganic optical sensors having a bandgap which is designed such that at least a part of the incident light beam is transmitted. Intransparent optical sensors may be provided by using intransparent electrodes and/or intransparent absorbing materials, such as organic and/or inorganic materials. As an example, an organic optical sensor may be provided having a thick metal electrode, such as a metal electrode having a thickness of more than 50 nm, preferably more than 100 nm. Additionally or alternatively, an inorganic optical sensor may be provided having an intransparent semiconductor material. As an example, typical CCD or CMOS camera chips provide intransparent properties. As an example, the stack may comprise one or more at least partially transparent DSCs or sDSCs and, on a side furthest away from the object, an intransparent CMOS or CCD chip. Other embodiments are feasible.
